Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19 (online at goo.gl/uPLFFs)
Preface to the Fourth Edition

As the teaching of calculus in many colleges and universities has become more problem-oriented with added emphasis on the use of calculators and computers, the theoretical gap between the material presented in calculus and the mathematical background expected (or at least hoped for) in advanced calculus and other more advanced courses has widened. In an attempt to narrow this gap and to better prepare students for the more abstract mathematics courses to follow, many colleges and universities have introduced courses that are now commonly called “transition courses.” In these courses, students are introduced to problems whose solution involves mathematical reasoning and a knowledge of proof techniques, where writing clear proofs is emphasized. Topics such as relations, functions and cardinalities of sets are encountered throughout theoretical mathematics courses. Lastly, transition courses often include theoretical aspects of number theory, combinatorics, abstract algebra and calculus. This textbook has been written for such a course.

The idea for this textbook originated in the early 1980s, long before transition courses became fashionable, during the supervision of undergraduate mathematics research projects. We came to realize that even advanced undergraduates lack a sound understanding of proof techniques and have difficulty writing correct and clear proofs. At that time, we developed a set of notes for these students. This was followed by the introduction of a transition course, for which a more detailed set of notes was written. The first edition of this book emanated from these notes, which in turn has ultimately led to this fourth edition.

While understanding proofs and proof techniques and writing good proofs are major goals here, these are not things that can be accomplished to any great degree in a single course during a single semester. These must continue to be emphasized and practiced in succeeding mathematics courses.

Our Approach

Since this textbook originated from notes that were written exclusively for undergraduates to help them understand proof techniques and to write good proofs, the tone is student-friendly. Numerous examples of proofs are presented in the text. Following common practice, we indicate the end of a proof with the square symbol ■. Often we precede a proof by a discussion, referred to as a proof strategy, where we think through what is needed to present a proof of the result in question. Other times, we find it useful to reflect on a proof we have just presented to point out certain key details. We refer to a discussion of this type as a proof analysis. Periodically, we present and solve problems, and we may find it convenient to discuss some features of the solution, which we refer to
simply as an *analysis*. For clarity, we indicate the end of a discussion of a proof strategy, proof analysis, analysis, or solution of an example with the diamond symbol ♦.

A major goal of this textbook is to help students learn to construct proofs of their own that are not only mathematically correct but clearly written. More advanced mathematics students should strive to present proofs that are convincing, readable, notationally consistent and grammatically correct. A secondary goal is to have students gain sufficient knowledge of and confidence with proofs so that they will recognize, understand and appreciate a proof that is properly written.

As with the first three editions, the fourth edition of this book is intended to assist the student in making the transition to courses that rely more on mathematical proof and reasoning. We envision that students taking a course based on this book have probably had a year of calculus (and possibly another course such as elementary linear algebra) although no specific prerequisite mathematics courses are required. It is likely that, prior to taking this course, a student’s training in mathematics consisted primarily of doing patterned problems; that is, students have been taught methods for solving problems, likely including some explanation as to why these methods worked. Students may very well have had exposure to some proofs in earlier courses but, more than likely, were unaware of the logic involved and of the method of proof being used. There may have even been times when the students were not certain what was being proved.

**New to This Edition**

The following changes and additions to the third edition have resulted in this fourth edition of the text:

- Presentation slides in PDF and LaTeX formats have been created to accompany every chapter. These presentations provide examples and exposition on key topics. Using short URLs (which are called out in the margin using the icon), these presentations are linked in the text beside the supplemental exercises at the end of each chapter. These slides can be used by instructors in lecture, or by students to learn and review key ideas.
- The new Chapter 7, “Reviewing Proof Techniques,” summarizes all the techniques that have been presented. The placement of this chapter allows instructors and students to review all of these techniques before beginning to explore different contexts in which proofs are used. This new chapter includes many new examples and exercises.
- The new Chapter 13, “Proofs in Combinatorics,” has been added because of a demand for such a chapter. Here, results and examples are presented in this important area of discrete mathematics. Numerous exercises are also included in this chapter.
- The new online Chapter 18, “Proofs with Real and Complex Numbers,” has been added to provide information on these two important classes of numbers. This chapter includes many important classical results on real numbers as well as important results from complex variables. In each case, detailed proofs are given.
Chapters 16 (Proofs in Ring Theory), 17 (Proofs in Linear Algebra), and 19 (Proofs in Topology) continue to exist online to allow faculty to tailor the course to meet their specific needs.

- More than 250 exercises have been added. Many of the new exercises fall into the moderate difficulty level and require more thought to solve.
- Section exercises for each chapter have been moved from the end of the chapter to the end of each section within a chapter. (Exceptions: for the review chapter 7 and the online chapters 16–19, all exercises remain at the end of the chapter.)
- In the previous edition, there were exercises at the end of each chapter called Additional Exercises. These summative exercises served to pull together the ideas from the various sections of the chapter. These exercises remain at the end of the chapters in this edition, but they have been renamed Supplemental Exercises.

Contents and Structure

Outline of Contents

Each of the Chapters 1–6 and 8–15 is divided into sections, and exercises for each section occur at the end of that section. There is also a final supplemental section of exercises for the entire chapter appearing at the end of that chapter.

Since writing good proofs requires a certain degree of competence in writing, we have devoted Chapter 0 to writing mathematics. The emphasis of this chapter is on effective and clear exposition, correct usage of symbols, writing and displaying mathematical expressions, and using key words and phrases. Although every instructor will emphasize writing in his or her own way, we feel that it is useful to read Chapter 0 periodically throughout the course. It will mean more as the student progresses through the course.

Chapter 1 contains a gentle introduction to sets, so that everyone has the same background and is using the same notation as we prepare for what lies ahead. No proofs involving sets occur until Chapter 4. Much of Chapter 1 may very well be a review for many.

Chapter 2 deals exclusively with logic. The goal here is to present what is needed to get into proofs as quickly as possible. Much of the emphasis in Chapter 2 is on statements, implications and quantified statements, including a discussion of mixed quantifiers. Sets are introduced before logic so that the student’s first encounter with mathematics here is a familiar one and because sets are needed to discuss quantified statements properly in Chapter 2.

The two proof techniques of direct proof and proof by contrapositive are introduced in Chapter 3 in the familiar setting of even and odd integers. Proof by cases is discussed in this chapter as well as proofs of “if and only if” statements. Chapter 4 continues this discussion in other settings, namely divisibility of integers, congruence, real numbers and sets.

The technique of proof by contradiction is introduced in Chapter 5. Since existence proofs and counterexamples have a connection with proof by contradiction, these also occur in Chapter 5. The topic of uniqueness (of an element with specified properties) is also addressed in Chapter 5.
Proof by mathematical induction occurs in Chapter 6. In addition to the Principle of Mathematical Induction and the Strong Principle of Mathematical Induction, this chapter includes proof by minimum counterexample.

Chapter 7 reviews all proof techniques (direct proof, proof by contrapositive, proof by contradiction and induction) introduced in Chapters 3–6. This chapter provides many examples to solidify the understanding of these techniques, emphasizing both how and when to use the techniques. Exercises in this chapter are distributed randomly with respect to the method of proof used.

The main goal of Chapter 8 (Prove or Disprove) concerns the testing of statements of unknown truth value, where it is to be determined, with justification, whether a given statement is true or false. In addition to the challenge of determining whether a statement is true or false, such problems provide added practice with counterexamples and the various proof techniques. Testing statements is preceded in this chapter by a historical discussion of conjectures in mathematics and a review of quantifiers.

Chapter 9 deals with relations, especially equivalence relations. Many examples involving congruence are presented and the set of integers modulo $n$ is described.

Chapter 10 involves functions, with emphasis on the properties of one-to-one (injective) and onto (subjective) functions. This gives rise to a discussion of bijective functions and inverses of functions. The well-defined property of functions is discussed in more detail in this chapter. In addition, there is a discussion of images and inverse images of sets with regard to functions as well as operations on functions, especially composition.

Chapter 11 deals with infinite sets and a discussion of cardinalities of sets. This chapter includes a historical discussion of infinite sets, beginning with Cantor and his fascination and difficulties with the Schröder–Bernstein Theorem, then proceeding to Zermelo and the Axiom of Choice, and ending with a proof of the Schröder–Bernstein Theorem.

All of the proof techniques are employed in Chapter 12, where numerous results in the area of number theory are introduced and proved.

Chapter 13 deals with proofs in the area of discrete mathematics called combinatorics. The primary goal of this chapter is to introduce the basic principles of counting such as multiplication, addition, pigeonhole and inclusion-exclusion. The concepts of permutations and combinations described here give rise to a wide variety of counting problems. In addition, Pascal triangles and the related binomial theorem are discussed. This chapter describes many proofs that occur in this area including many examples of how this subject can be used to solve a variety of problems.

Chapter 14 deals with proofs that occur in calculus. Because these proofs are quite different from those previously encountered but are often more predictable in nature, many illustrations are given that involve limits of sequences and functions and their connections with infinite series, continuity and differentiability.

The final Chapter 15 deals with modern algebra, beginning with binary operations and moving into proofs that are encountered in the area of group theory.

It is our experience that many students have benefited by reading and solving problems in these later chapters that deal with courses they are currently taking or are about to take. The same is true for the following online chapters.

The study of proofs in modern algebra continues in the first online Chapter 16 (goo.gl/zKdQor), where the major topic is ring theory. Proofs concerning integral domains and fields are presented here as well.
In Chapter 17 (goo.gl/Tmh2ZB), we discuss proofs in linear algebra, where the concepts of vector spaces and linear transformations are emphasized.

Even though real numbers (and, to a lesser degree, complex numbers) occur throughout mathematics, there are many properties of these two classes of numbers of which students may be unaware. This is the topic for Chapter 18 (goo.gl/ymv5kJ).

The final online chapter is Chapter 19 (goo.gl/bWFRMu), where we discuss proofs in topology. Included in this chapter are proofs involving metric spaces and topological spaces. A major topic here is open and closed sets.

Exercises
There are over 1000 exercises in Chapters 1–19. The degree of difficulty of the exercises ranges from routine to medium difficulty to moderately challenging. As mentioned earlier, the fourth edition contains more exercises in the moderately difficult category. Types of exercises include:

- Exercises that present students with statements, asking students to decide whether they are true or false (with justification).
- Proposed proofs of statements, asking if the argument is valid.
- Proofs without a statement given, which ask students to supply a statement of what has been proved.
- Exercises that call upon students to make conjectures of their own and possibly to provide proofs of these conjectures.

Chapter 3 is the first chapter in which students will be called upon to write proofs. At such an early stage, we feel that students need to (1) concentrate on constructing a valid proof and not be distracted by unfamiliarity with the mathematics, (2) develop some self-confidence with this process and (3) learn how to write a proof properly. With this in mind, many of the exercises in Chapter 3 have been intentionally structured so as to be similar to the examples in that chapter.

Exercises for each section in Chapters 1–6 and 8–15 occur at the end of a section (section exercises) and additional exercises for the entire chapter (supplemental exercises) appear at the end of the chapter as do chapter exercises for Chapter 7. Answers or hints to the odd-numbered section exercises appear at the end of the text as do odd-numbered chapter exercises for Chapter 7. One should also keep in mind, however, that proofs of results are not unique in general.

Teaching a Course from This Text
Although a course using this textbook could be designed in many ways, here are our views on such a course. As we noted earlier, we think it is useful for students to reread (at least portions of) Chapter 0 throughout the course, as we feel that with each reading, the chapter becomes more meaningful. The first part of Chapter 1 (Sets) will likely be familiar to most students, although the last part may not. Chapters 2–6 will probably be part of any such course, although certain topics could receive varying degrees of emphasis (with perhaps proof by minimum counterexample in Chapter 6 possibly even omitted). Chapter 7 reviews all proof techniques introduced in Chapters 3–6. If the instructor believes that students have obtained a strong understanding of these techniques,
this chapter could be omitted. Nevertheless, we feel it is good for students to read this chapter and try solving the exercises. Instructors who choose to omit Chapter 7 might find it useful to assign exercises from this chapter, asking students to determine which proof technique is to be used.

One could spend much or little time on Chapter 8, depending on how much time is used to discuss the large number of “prove or disprove” exercises. We think that most of Chapters 9 and 10 would be covered in such a course. It would be useful to cover some of the fundamental ideas addressed in Chapter 11 (Cardinalities of Sets). As time permits, portions of the later chapters could be covered, especially those of interest to the instructor, including the possibility of going to the web site for even more variety.

Supplements and Technology

Online Chapters

Four additional chapters, Chapters 16–19 (dealing with proofs in ring theory, linear algebra, real and complex numbers, and topology), can be found by going to: goo.gl/bf2Nb3.

Instructor’s Solutions Manual (downloadable)

The Instructor’s Solutions Manual, written by the authors, provides worked-out solutions for all exercises in the text. It is available for download to qualified instructors from the Pearson Instructor Resource Center https://www.pearson.com/us/sign-in.html.

Chapter Presentations

This icon found beside the supplemental exercises for each chapter, indicates a chapter presentation. The short URLs in the margin of the text provide students with direct access to the presentations in PDF form. The URL goo.gl/bf2Nb3 provides access to the complete library of presentations in both PDF and editable LaTeX (Beamer) formats.

Acknowledgments

It is a pleasure to thank the reviewers of the third edition and those who made valuable suggestions for the writing of the fourth edition:

Brendon Kerr Ballenger-Fazzone, Florida State University
José Flores, University of South Dakota
Eric Gottlieb, Rhodes College
Teresa Haynes, East Tennessee State University
William Heller, University of Texas Rio Grande Valley
Thomas Kent, Marywood University
Anita Mareno, Penn State University, Harrisburg
George Poole, East Tennessee State University
John Saccoman, Seton Hall University
Sam Smith, Saint Joseph’s University
Kristopher Tapp, Saint Joseph’s University
Jacob Wildstrom, University of Louisville

We are fortunate to have received such great support in the writing of this fourth edition. We especially thank the following from Pearson Education: Jeff Weidenaar, Executive Editor, Mathematics; Jennifer Snyder, Editorial Assistant, Higher Education; Tara Corpuz, Content Producer. We also thank Ira Chawla, Customer Service Head, Digital Publishing Group, APTARA; Bret D. Workman, Editing and Proofreading Services; Jennifer Blue, SUNY Empire State College, who have been of great assistance in guiding us through the final stages of the fourth edition.

Gary Chartrand
Albert D. Polimeni
Ping Zhang
Communicating Mathematics

Quite likely, the mathematics you have already encountered consists of doing problems using a specific approach or procedure. These may include solving equations in algebra, simplifying algebraic expressions, verifying trigonometric identities, using certain rules to find and simplify the derivatives of functions, and setting up and evaluating a definite integral that gives the area of a region or the volume of a solid. Accomplishing all of these is often a matter of practice.

Many of the methods used to solve problems in mathematics are based on results in mathematics that were discovered by people and shown to be true. This kind of mathematics may very well be new to you and, as with anything that’s new, there are things to be learned. But learning something new can be (and, in fact should be) fun. There are several steps involved here. The first step is discovering something in mathematics that we believe to be true. How does one discover new mathematics? This usually comes about by considering examples and observing that a pattern seems to be occurring with the examples. This may lead to a guess on our part as to what appears to be happening. We then have to convince ourselves that our guess is correct. In mathematics this involves constructing a proof showing what we believe to be true is, in fact, true. But this is not enough. We need to convince others that we are right. So we need to write a proof that is written so clearly and so logically that people who know the methods of mathematics will be convinced. Where mathematics differs from all other scholarly fields is that once a proof has been given of a certain mathematical statement, there is no longer any doubt. This statement is true. Period. There is no other alternative.

Our main emphasis here will be in learning how to construct mathematical proofs and learning to write proofs in such a manner that these proofs will be clear to and understood by others. Even though learning to guess new mathematics is important and can be fun, we will spend only a little time on this as it often requires an understanding of more mathematics than can be discussed at this time. But why would we want to discover new mathematics? While one possible answer is that it comes from the curiosity that most mathematicians possess, a more common explanation is that we have a problem to solve that requires knowing that some mathematical statement is true.
Chapter 0  Communicating Mathematics

0.1 LEARNING MATHEMATICS

One of the major goals of this book is to assist you as you progress from an individual who uses mathematics to an individual who understands mathematics. Perhaps this will mark the beginning of you becoming someone who actually develops mathematics of your own. This is an attainable goal if you have the desire.

The fact that you’ve gone this far in your study of mathematics suggests that you have ability in mathematics. This is a real opportunity for you. Much of the mathematics that you will encounter in the future is based on what you are about to learn here. The better you learn the material and the mathematical thought process now, the more you will understand later. To be sure, any area of study is considerably more enjoyable when you understand it. But getting to that point will require effort on your part.

There are probably as many excuses for doing poorly in mathematics as there are strategies for doing well in mathematics. We have all heard students say (sometimes, remarkably, even with pride) that they are not good at mathematics. That’s only an alibi. Mathematics can be learned like any other subject. Even some students who have done well in mathematics say that they are not good with proofs. This, too, is unacceptable. What is required is determination and effort. To have done well on an exam with little or no studying is nothing to be proud of. Confidence based on being well prepared is good, however.

Here is some advice that has worked for several students. First, it is important to understand what goes on in class each day. This means being present and being prepared for every class. After each class, recopy any lecture notes. When recopying the notes, express sentences in your own words and add details so that everything is as clear as possible. If you run into snags (and you will), talk them over with a classmate or your instructor. In fact, it’s a good idea (at least in our opinion) to have someone with whom to discuss the material on a regular basis. Not only does it often clarify ideas, it gets you into the habit of using correct terminology and notation.

In addition to learning mathematics from your instructor, solidifying your understanding by careful note-taking and talking with classmates, your textbook is (or at least should be) an excellent source as well. Read your textbook carefully with pen (or pencil) and paper in hand. Make a serious effort to do every homework problem assigned and, eventually, be certain that you know how to solve them. If there are exercises in the textbook that have not been assigned, you might even try to solve these as well. Another good idea is to try to create your own problems. In fact, when studying for an exam, try creating your own exam. If you start doing this for all of your classes, you might be surprised at how good you become. Creativity is a major part of mathematics. Discovering mathematics not only contributes to your understanding of the subject but has the potential to contribute to mathematics itself. Creativity can come in all forms. The following quote is from the well-known writer J. K. Rowling (author of the Harry Potter novels).

"Sometimes ideas just come to me. Other times I have to sweat and almost bleed to make ideas come. It’s a mysterious process, but I hope I never find out exactly how it works."

In her book Defying Gravity: The Creative Career of Stephen Schwartz, from Godspell to Wicked, Carol de Gier writes a biography of Stephen Schwartz, one of the most
successful composer-lyricists, in which she discusses not only creativity in music but how an idea can lead to something special and interesting and how creative people may have to deal with disappointment. Indeed, de Giere dedicates her book to the creative spirit within each of us. While Schwartz wrote the music for such famous shows as Godspell and Wicked, he discusses creativity head-on in the song “The Spark of Creation,” which he wrote for the musical Children of Eden. In her book, de Giere writes:

_In many ways, this song expresses the theme of Stephen Schwartz’s life – the naturalness and importance of the creative urge within us. At the same time he created an anthem for artists._

In mathematics our goal is to seek the truth. Finding answers to mathematical questions is important, but we cannot be satisfied with this alone. We must be certain that we are right and that our explanation for why we believe we are correct is convincing to others. The reasoning we use as we proceed from what we know to what we wish to show must be logical. It must make sense to others, not just to ourselves.

There is joint responsibility here. As writers, it is our responsibility to give an accurate, clear argument with enough details provided to allow the reader to understand what we have written and to be convinced. It is the reader’s responsibility to know the basics of logic and to study the concepts involved so that a well-presented argument will be understood. Consequently, in mathematics writing is important, _very_ important. Is it _really_ important to write mathematics well? After all, isn’t mathematics mainly equations and symbols? Not at all. It is not only important to write mathematics well, it is important to write well. You will be writing the rest of your life, at least reports, letters and email. Many people who never meet you will know you only by what you write and how you write.

Mathematics is a sufficiently complicated subject that we don’t need vague, hazy and boring writing to add to it. A teacher has a very positive impression of a student who hands in well-written and well-organized assignments and examinations. You want people to enjoy reading what you’ve written. It is important to have a good reputation as a writer. It’s part of being an educated person. Especially with the large number of email letters that so many of us write, it has become commonplace for writing to be more casual. Although all people would probably subscribe to this (since it is more efficient), we should know how to write well, formally and professionally, when the situation requires it.

You might think that considering how long you’ve been writing and that you’re set in your ways, it will be very difficult to improve your writing. Not really. If you want to improve, you can and will. Even if you are a good writer, your writing can always be improved. Ordinarily, people don’t think much about their writing. Often just thinking about your writing is the first step to writing better.

## 0.2 WHAT OTHERS HAVE SAID ABOUT WRITING

Many people who are well known in their areas of expertise have expressed their thoughts about writing. Here are quotes by some of these individuals.
Chapter 0  Communicating Mathematics

Anything that helps communication is good. Anything that hurts it is bad.
I like words more than numbers, and I always did—conceptual more than computational.

Paul Halmos, mathematician

Writing is easy. All you have to do is cross out all the wrong words.

Mark Twain, author (The Adventures of Hucklebery Finn)

You don’t write because you want to say something; you write because you’ve got something to say.

F. Scott Fitzgerald, author (The Great Gatsby)

Writing comes more easily if you have something to say.

Scholem Asch, author

Either write something worth reading or do something worth writing.

Benjamin Franklin, statesman, writer, inventor

What is written without effort is in general read without pleasure.

Samuel Johnson, writer

Easy reading is damned hard writing.

Nathaniel Hawthorne, novelist (The Scarlet Letter)

Everything that is written merely to please the author is worthless.
The last thing one knows when writing a book is what to put first.
I have made this letter longer because I lack the time to make it short.

Blaise Pascal, mathematician and physicist

The best way to become acquainted with a subject is to write a book about it.

Benjamin Disraeli, prime minister of England

In a very real sense, the writer writes in order to teach himself, to understand himself, to satisfy himself; the publishing of his ideas, though it brings gratification, is a curious anticlimax.

Alfred Kazin, literary critic

The skill of writing is to create a context in which other people can think.

Edwin Schlossberg, exhibit designer

A writer needs three things, experience, observation, and imagination, any two of which, at times any one of which, can supply the lack of the other.

William Faulkner, writer (The Sound and the Fury)

If confusion runs rampant in the passage just read,
It may very well be that too much has been said.
So that’s what he meant! Then why didn’t he say so?

Frank Harary, mathematician

A mathematical theory is not to be considered complete until you have made it so clear that you can explain it to the first man whom you meet on the street.

David Hilbert, mathematician
0.3 Mathematical Writing

Everything should be made as simple as possible, but not simpler.
Albert Einstein, physicist

Never let anything you write be published without having had others critique it.
Donald E. Knuth, computer scientist and writer

Some books are to be tasted, others to be swallowed, and some few to be chewed and digested.
Reading maketh a full man, conference a ready man, and writing an exact man.
Francis Bacon, writer and philosopher

Judge an article not by the quality of what is framed and hanging on the wall, but by the quality of what’s in the wastebasket.
Anonymous (Quote by Leslie Lamport)

We are all apprentices in a craft where no-one ever becomes a master.
Ernest Hemingway, author (For Whom the Bell Tolls)

There are three rules for writing a novel. Unfortunately, no one knows what they are.
W. Somerset Maugham, author (Of Human Bondage)

0.3 MATHEMATICAL WRITING

Most of the quotes given above pertain to writing in general, not to mathematical writing in particular. However, these suggestions for writing apply as well to writing mathematics. For us, mathematical writing means writing assignments for a mathematics course (particularly a course with proofs). Such an assignment might consist of writing a single proof, writing solutions to a number of problems, or perhaps writing a term paper which, more than likely, includes definitions, examples, background and proofs. We’ll refer to any of these as an “assignment.” Your goal should be to write correctly, clearly and in an interesting manner.

Before you even begin to write, you should have already thought about a number of things. First, you should know what examples and proofs you plan to include if this is appropriate for your assignment. You should not be overly concerned about writing good proofs on your first attempt – but be certain that you do have proofs.

As you’re writing your assignment, you must be aware of your audience. What is the target group for your assignment? Of course, it should be written for your instructor. But it should be written so that a classmate would understand it. As you grow mathematically, your audience will grow with you and you will adapt your writing to this new audience.

Give yourself enough time to write your assignment. Don’t try to put it together just a few minutes before it’s due. The disappointing result will be obvious to your instructor. And to you! Find a place to write that is comfortable for you: your room, an office, a study room, the library and sitting at a desk, at a table, in a chair. Do what works best for you. Perhaps you write best when it’s quiet or when there is background music.
6 Chapter 0  Communicating Mathematics

Now that you’re comfortably settled and have allowed enough time to do a good job, let’s put a plan together. If the assignment is fairly lengthy, you may need an outline, which, most likely, will include one or more of the following:

1. background and motivation
2. definitions to be presented and possibly notation to be used
3. examples to include
4. results to be presented (whose proofs have already been written, probably in rough form)
5. references to other results you intend to use
6. the order of everything mentioned above.

If the assignment is a term paper, it may include extensive background material and may need to be carefully motivated. The subject of the paper should be placed in perspective. Where does it fit in with what we already know?

Many writers write in “spirals.” Even though you have a plan for your assignment that includes an ordered list of things you want to say, it is likely that you will reach some point (perhaps sooner than you think) when you realize that you should have included something earlier – perhaps a definition, a theorem, an example, some notation. (This happened to us many times while writing this textbook.) Insert the missing material, start over again and write until once again you realize that something is missing. It is important, as you reread, that you start at the beginning each time. Then repeat the steps listed above.

We are about to give you some advice, some “pointers,” about writing mathematics. Such advice is necessarily subjective. Not everyone subscribes to these suggestions on writing. Indeed, writing “experts” don’t agree on all issues. For the present, your instructor will be your best guide. But writing does not follow a list of rules. As you mature mathematically, perhaps the best advice about your writing is the same advice given by Jiminy Cricket to Disney’s Pinocchio: *Always let your conscience be your guide*. You must be yourself. And one additional piece of advice: Be careful about accepting advice on writing. Originality and creativity don’t follow rules. Until you reach the stage of being comfortable and confident with your own writing, however, we believe that it is useful to consider a few writing tips.

Since a number of these writing tips may not make sense (since, after all, we don’t even have anything to write yet), it will probably be most useful to return to this chapter periodically as you proceed through the chapters that follow.

0.4 USING SYMBOLS

Since mathematics is a symbol-oriented subject, mathematical writing involves a mixture of words and symbols. Here are several guidelines to which a number of mathematicians subscribe.

1. Never start a sentence with a symbol.
   Writing mathematics follows the same practice as writing all sentences, namely that the first word should be capitalized. This is confusing if the
0.4 Using Symbols

sentence were to begin with a symbol since the sentence appears to be incomplete. Also, in general, a sentence sounds better if it starts with a word. Instead of writing:

\[ x^2 - 6x + 8 = 0 \]

write:

The equation \( x^2 - 6x + 8 = 0 \) has two distinct roots.

2. Separate symbols not in a list by words if possible.

Separating symbols by words makes the sentence easier to read and therefore easier to understand. The sentence:

With the exception of \( a \), \( b \) is the only root of \((x - a)(x - b) = 0\).

would be clearer if it were written as:

With the exception of \( a \), the number \( b \) is the only root of \((x - a)(x - b) = 0\).

3. Except when discussing logic, avoid writing the following symbols in your assignment:

\( \Rightarrow \), \( \forall \), \( \exists \), \( \ni \), etc.

The first four symbols stand for “implies,” “for every,” “there exists” and “such that,” respectively. You may have already seen these symbols and know what they mean. If so, this is good. It is useful when taking notes or writing early drafts of an assignment to use shorthand symbols but many mathematicians avoid such symbols in their professional writing. (We will visit these symbols later.)

4. Be careful about using i.e. and e.g.

These stand for that is and for example, respectively. There are situations when writing the words is preferable to writing the abbreviations as there may be confusion with nearby symbols. For example, \( \sqrt{-1} \) and \( \lim_{n \to \infty} \left( 1 + \frac{1}{n} \right)^n \) are not rational numbers, that is, \( i \) and \( e \) are not rational numbers.

5. Write out integers as words when they are used as adjectives and when the numbers are relatively small or are easy to describe in words. Write out numbers numerically when they specify the value of something.

There are exactly two groups of order 4.

Fifty million Frenchmen can’t be wrong.

There are one million positive integers less than 1,000,001.

6. Don’t mix words and symbols improperly.

Avoid writing:

Every integer \( \geq 2 \) is a prime or is composite.

It is preferable to write:

Every integer exceeding 1 is prime or composite.
8 Chapter 0 Communicating Mathematics

or

If $n \geq 2$ is an integer, then $n$ is prime or composite.

Although

Since $(x - 2)(x - 3) = 0$, it follows that $x = 2$ or 3.

sounds correct, it is not written correctly. It should be:

Since $(x - 2)(x - 3) = 0$, it follows that $x = 2$ or $x = 3$.

7. Avoid using a symbol in the statement of a theorem when it’s not needed.
Don’t write:

Theorem Every bijective function $f$ has an inverse.

Delete “$f$.” It serves no useful purpose. The theorem does not depend on what the function is called. A symbol should not be used in the statement of a theorem (or in its proof) exactly once. If it is useful to have a name for an arbitrary bijective function in the proof (as it probably will be), then “$f$” can be introduced there.

8. Explain the meaning of every symbol that you introduce.
Although what you intended may seem clear, don’t assume this. For example, if you write $n = 2k + 1$ and $k$ has never appeared before, then say that $k$ is an integer (if indeed $k$ is an integer).

9. Use “frozen symbols” properly.
If $m$ and $n$ are typically used for integers (as they probably are), then don’t use them for real numbers. If $A$ and $B$ are used for sets, then don’t use these as typical elements of a set. If $f$ is used for a function, then don’t use this as an integer. Write symbols that the reader would expect. To do otherwise could very well confuse the reader.

10. Use consistent symbols.
Unless there is some special reason to the contrary, use symbols that “fit” together. Otherwise, it is distracting to the reader.
Instead of writing:

If $x$ and $y$ are even integers, then $x = 2a$ and $y = 2r$ for some integers $a$ and $r$.

replace $2r$ by $2b$ (where then, of course, we write “for some integers $a$ and $b$”). On the other hand, you might prefer to write $x = 2r$ and $y = 2x$.

0.5 WRITING MATHEMATICAL EXPRESSIONS

There will be numerous occasions when you will want to write mathematical expressions in your assignment, such as algebraic equations, inequalities and formulas. If these expressions are relatively short, then they should probably be written within the text of the proof or discussion. (We’ll explain this in a moment.) If the expressions are rather lengthy, then it is probably preferred for these expressions to be written as “displays.”
0.5 Writing Mathematical Expressions

For example, suppose that we are discussing the Binomial Theorem. (It’s not important if you don’t recall what this theorem is.) It’s possible that what we are writing includes the following passage:

For example, if we expand \((a + b)^4\), then we obtain \((a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4\).

It would probably be better to write the expansion of \((a + b)^4\) as a display, where the mathematical expression is placed on a line or lines by itself and is centered. This is illustrated below.

For example, if we expand \((a + b)^4\), then we obtain

\[(a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4.\]

If there are several mathematical expressions that are linked by equal signs and inequality symbols, then we would almost certainly write this as a display. For example, suppose that we wanted to write \(n^3 + 3n^2 - n + 4\) in terms of \(k\), where \(n = 2k + 1\). A possible display is given next:

Since \(n = 2k + 1\), it follows that

\[
\begin{align*}
n^3 + 3n^2 - n + 4 &= (2k + 1)^3 + 3(2k + 1)^2 - (2k + 1) + 4 \\
&= (8k^3 + 12k^2 + 6k + 1) + 3(4k^2 + 4k + 1) - 2k - 1 + 4 \\
&= 8k^3 + 24k^2 + 16k + 7 = 8k^3 + 24k^2 + 16k + 6 + 1 \\
&= 2(4k^3 + 12k^2 + 8k + 3) + 1.
\end{align*}
\]

Notice how the equal signs are lined up. (We wrote two equal signs on one line since that line would have contained very little material otherwise, as well as to balance the lengths of the lines better.)

Let’s return to the expression \((a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4\) for a moment. If we were to write this expression in the text of a paragraph (as we are doing) and if we find it necessary to write portions of this expression on two separate lines, then this expression should be broken so that the first line ends with an operation or comparative symbol such as \(+\), \(-\), \(<\), \(>\), \(\ge\) or \(\le\). In other words, the second line should not begin with one of these symbols. The reason for doing this is that ending the line with one of these symbols alerts the reader that more will follow; otherwise, the reader might conclude (incorrectly) that the portion of the expression appearing on the first line is the entire expression. Consequently, write

For example, if we expand \((a + b)^4\), then we obtain \((a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4\).

and not

For example, if we expand \((a + b)^4\), then we obtain \((a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4\).

If there is an occasion to refer to an expression that has already appeared, then this expression should have been written as a display and labeled as below:

\[(a + b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4.\] (1)

Then we can simply refer to expression (1) rather than writing it out each time.
10 Chapter 0 Communicating Mathematics

0.6 COMMON WORDS AND PHRASES IN MATHEMATICS

There are some words and phrases that appear so often in mathematical writing that it is useful to discuss them.

1. *I* We One Let’s

   I will now show that $n$ is even.
   We will now show that $n$ is even.
   One now shows that $n$ is even.
   Let’s now show that $n$ is even.

   These are four ways that we might write a sentence in a proof. Which of these sounds the best to you? It is not considered good practice to use “I” unless you are writing a personal account of something. Otherwise, “I” sounds egotistical and can be annoying. Using “one” is often awkward. Using “we” is standard practice in mathematics. This word also brings the reader into the discussion with the author and gives the impression of a team effort. The word “let’s” accomplishes this as well but is much less formal. There is a danger of being too casual, however. In general, your writing should be balanced, maintaining a professional style. Of course, there is the possibility of avoiding all of these words:

   The integer $n$ is now shown to be even.

2. Clearly Obviously Of course Certainly

   These and similar words can turn a reader off if what’s written is not clear to the reader. It can give the impression that the author is putting the reader down. These words should be used sparingly and with caution. If they are used, then at least be certain that what you say is true. There is also the possibility that the writer (a student?) has a lack of understanding of the mathematics or is not being careful and is using these words as a cover-up. This gives us even more reasons to avoid these words.

3. Any Each Every

   This statement is true for any integer $n$.

   Does this mean that the statement is true for *some* integer $n$ or *all* integers $n$? Since the word “any” can be vague, perhaps it is best to avoid it. If by “any,” we mean “each” or “every,” then use one of these two words instead. When the word “any” is encountered, most of the time the author means “each” or “every.”

4. Since …, then …

   A number of people connect these two words. You should use either “If …, then …” (should this be the intended meaning) or “Since …, it follows that …” or, possibly, “Since …, we have …”. For example, it is correct to write

   If $n^2$ is even, then $n$ is even.
or

Since \(n^2\) is even, it follows that \(n\) is even.

or perhaps

Since \(n^2\) is even, \(n\) is even.

but avoid

Since \(n^2\) is even, then \(n\) is even.

In this context, the word “since” can be replaced by “because.”

5. \textit{Therefore} \textit{Thus} \textit{Hence} \textit{Consequently} \textit{So} \textit{It follows that} \textit{This implies that}

This is tricky. Mathematicians cannot survive without these words. Often within a proof, we proceed from something we’ve just learned to something else that can be concluded from it. There are many (many!) openings to sentences that attempt to say this. Although each of the words or phrases is suitable, it is good to introduce some variety into your writing and not use the same words or phrases any more often than necessary.

6. \textit{That} \textit{Which}

These words are often confused with each other. Sometimes they are interchangeable; more often they are not.

The solution to the equation is the number less than 5 that is positive. \hfill (2)

The solution to the equation is the number less than 5 which is positive. \hfill (3)

Which of these two sentences is correct? The simple answer is: Both are correct – or, at least, both might be correct.

For example, sentence (2) could be the response to the question: Which of the numbers -2, 3 and 5 is the solution of the equation? Sentence (3) could be the response to the question: Which of the numbers 4.9 and 5.0 is the solution of the equation?

The word “that” introduces a \textit{restrictive clause} and, as such, the clause is essential to the meaning of the sentence. That is, if sentence (2) were written only as “The solution to the equation is the number less than 5,” then the entire meaning is changed. Indeed, we no longer know what the solution of the equation is.

On the other hand, the word “which” does not introduce a restrictive clause. It introduces a nonrestrictive (or parenthetical) clause. A \textit{nonrestrictive clause} only provides additional information that is not essential to the meaning of the sentence. In sentence (3) the phrase “which is positive” simply provides more information about the solution. This clause may have been added because the solution to an earlier equation is negative. In fact, it would be more appropriate to add a comma:

The solution to the equation is the number less than 5, which is positive.
Chapter 0   Communicating Mathematics

For another illustration, consider the following two statements:

I always keep the math text that I like with me.  \hspace{2cm} (4)

I always keep the math text which I like with me.  \hspace{2cm} (5)

What is the difference between these two sentences? In (4), the writer of the sentence clearly has more than one math text and is referring to the one that he/she likes. In (5), the writer has only one math text and is providing the added information that he/she likes it. The nonrestrictive clause in (5) should be set off by commas:

I always keep the math text, which I like, with me.

A possible guideline to follow as you seek to determine whether “that” or “which” is the proper word to use is to ask yourself: Does it sound right if it reads “which, by the way”? In general, “that” is normally used considerably more often than “which.” Hence, the advice here is: Beware of wicked which’s!

While we are discussing the word “that,” we mention that the words “assume” and “suppose” often precede restrictive clauses and, as such, the word “that” should immediately follow one of these words. Omitting “that” leaves us with an implied “that.” Many mathematicians prefer to include it rather than omit it.

In other words, instead of writing:

Assume \( N \) is a normal subgroup.

many would write

Assume that \( N \) is a normal subgroup.

0.7 SOME CLOSING COMMENTS ABOUT WRITING

1. Use good English. Write in complete sentences, ending each sentence with a period (or a question mark when appropriate) and capitalize the first word of each sentence. (Remember: No sentence begins with a symbol!)

2. Capitalize theorem and lemma as in Theorem 1.15 and Lemma 4.11. (For example, write: In order to verify the truth of Result 3.14, we first prove the following lemma.)

3. Many mathematicians do not hyphenate words containing the prefix “non,” such as

   nonempty, nonnegative, nondecreasing, nonzero.

4. Many words that occur often in mathematical writing are commonly misspelled. Among these are:

   commutative (independent of order)
   complement (supplement, balance, remainder)
   consistent (conforming, agreeing)
   feasible (suitable, attainable)
0.7 Some Closing Comments About Writing

its (possessive, not “it is”)
occurrence (incident)
parallel (non-intersecting)
preceding (foregoing, former)
principle (postulate, regulation, rule)
proceed (continue, move on)

and, of course,
corollary, lemma, theorem.

5. There are many pairs of words that fit together in mathematics (while
interchanging words among the pairs do not). For example,

We ask questions.
We pose problems.
We present solutions.
We prove theorems.
We solve problems.

and
We conclude this chapter.

The Chapter Presentation for Chapter 0 can be found at goo.gl/pC77jw
1

Sets

In this initial chapter, you will be introduced to, or more than likely be reminded of, a fundamental idea that occurs throughout mathematics: sets. Indeed, a set is an object from which every mathematical structure is constructed (as we will often see in the succeeding chapters). Although there is a formal subject called set theory in which the properties of sets follow from a number of axioms, this is neither our interest nor our need. It is our desire to keep the discussion of sets informal without sacrificing clarity. It is almost a certainty that portions of this chapter will be familiar to you. Nevertheless, it is important that we understand what is meant by a set, how mathematicians describe sets, the notation used with sets and several concepts that involve sets.

You’ve been experiencing sets all your life. In fact, all of the following are examples of sets: the students in a particular class who have a smartphone, the items on a shopping list, the integers. As a small child, you learned to say the alphabet. When you did this, you were actually listing the letters that make up the set we call the alphabet. A set is a collection of objects. The objects that make up a set are called its elements (or members). The elements of a softball team are the players, while the elements of the alphabet are letters.

It is customary to use capital (upper case) letters (such as $A, B, C, S, X, Y$) to designate sets and lower case letters (for example, $a, b, c, s, x, y$) to represent elements of sets. If $a$ is an element of the set $A$, then we write $a \in A$; if $a$ does not belong to $A$, then we write $a \notin A$.

1.1 DESCRIBING A SET

There will be many occasions when we (or you) will need to describe a set. The most important requirement when describing a set is to make it clear precisely which elements belong to the set.

If a set consists of a small number of elements, then this set can be described by explicitly listing its elements between braces (curly brackets) where the elements are separated by commas. Thus $S = \{1, 2, 3\}$ is a set, consisting of the numbers 1, 2 and 3. The order in which the elements are listed doesn’t matter. Thus the set $S$ just mentioned could be written as $S = \{3, 2, 1\}$ or $S = \{2, 1, 3\}$, for example. They describe the same set. If a set $T$ consists of the first five letters of the alphabet, then it is not essential that we
write \( T = \{a, b, c, d, e\} \), that is, the elements of \( T \) need not be listed in alphabetical order. On the other hand, listing the elements of \( T \) in any other order may create unnecessary confusion.

The set \( A \) of all people who signed the Declaration of Independence and later became president of the United States is \( A = \{\) John Adams, Thomas Jefferson \(\} \) and the set \( B \) of all positive even integers less than 20 is \( B = \{2, 4, 6, 8, 10, 12, 14, 16, 18\} \). Some sets contain too many elements to be listed this way. Perhaps even the set \( B \) just given contains too many elements to describe in this manner. In such cases, the ellipsis or “three dot notation” is often helpful. For example, \( X = \{1, 3, 5, \ldots, 49\} \) is the set of all positive odd integers less than 50; while \( Y = \{2, 4, 6, \ldots\} \) is the set of all positive even integers. The three dots mean “and so on” for \( Y \) and “and so on up to” for \( X \).

A set need not contain any elements. Although it may seem peculiar to consider sets without elements, these kinds of sets occur surprisingly often and in a variety of settings. For example, if \( S \) is the set of real number solutions of the equation \( x^2 + 1 = 0 \), then \( S \) contains no elements. There is only one set that contains no elements and it is called the empty set (or sometimes the null set or void set). The empty set is denoted by \( \emptyset \). We also write \( \emptyset = \{\} \). In addition to the example given above, the set of all real numbers \( x \) such that \( x^2 < 0 \) is also empty.

The elements of a set may in fact be sets themselves. The symbol \( \cup \) below indicates the conclusion of an example.

**Example 1.1**

The set \( S = \{1, 2, \{1, 2\}, \emptyset\} \) consists of four elements, two of which are sets, namely, \( \{1, 2\} \) and \( \emptyset \). If we write \( C = \{1, 2\} \), then we can also write \( S = \{1, 2, C, \emptyset\} \).

The set \( T = \{0, \{1, 2, 3\}, 4, 5\} \) also has four elements, namely, the three integers 0, 4 and 5 and the set \( \{1, 2, 3\} \). Even though \( 2 \in \{1, 2, 3\} \), the number 2 is not an element of \( T \); that is, \( 2 \notin T \).

Often sets consist of those elements satisfying some condition or possessing some specified property. In this case, we can define such a set as \( S = \{x : p(x)\} \), where, by this, we mean that \( S \) consists of all those elements \( x \) satisfying some condition \( p(x) \) concerning \( x \). Some mathematicians write \( S = \{x \mid p(x)\} \); that is, some prefer to write a vertical line rather than a colon (which, by itself here, is understood to mean “such that”). For example, if we are studying real number solutions of equations, then

\[
S = \{x : (x - 1)(x + 2)(x + 3) = 0\}
\]

is the set of all real numbers \( x \) such that \((x - 1)(x + 2)(x + 3) = 0\), that is, \( S \) is the solution set of the equation \((x - 1)(x + 2)(x + 3) = 0\). We could have written \( S = \{1, -2, -3\} \); however, even though this way of expressing \( S \) is apparently simpler, it does not tell us that we are interested in the solutions of a particular equation. The absolute value \( |x| \) of a real number \( x \) is \( x \) if \( x \geq 0 \); while \( |x| = -x \) if \( x < 0 \). Therefore,

\[
T = \{x : |x| = 2\}
\]

is the set of all real numbers having absolute value 2, that is, \( T = \{2, -2\} \). In the sets \( S \) and \( T \) that we have just described, we understand that “\( x \)” refers to a real number \( x \). If there is a possibility that this wouldn’t be clear to the reader, then we should specifically say that \( x \) is a real number. We’ll say more about this soon. The set

\[
P = \{x : x \text{ has been a president of the United States}\}
\]
describes, rather obviously, all those individuals who have been president of the United States. So, Abraham Lincoln belongs to \( P \) but Benjamin Franklin does not.

**Example 1.2** Let \( A = \{3, 4, 5, \ldots, 20\} \). If \( B \) denotes the set consisting of those elements of \( A \) that are less than 8, then we can write

\[
B = \{x \in A : x < 8\} = \{3, 4, 5, 6, 7\}. \quad \blacktriangle
\]

Some sets are encountered so often that they are given special notation. We use \( \mathbb{N} \) to denote the set of all positive integers (or natural numbers); that is, \( \mathbb{N} = \{1, 2, 3, \ldots\} \). The set of all integers (positive, negative and zero) is denoted by \( \mathbb{Z} \). So \( \mathbb{Z} = \{\ldots, -2, -1, 0, 1, 2, \ldots\} \). With the aid of the notation we've just introduced, we can now describe the set \( E = \{\ldots, -4, -2, 0, 2, 4, \ldots\} \) of even integers by

\[
E = \{y : y \text{ is an even integer}\} \quad \text{or} \quad E = \{2x : x \text{ is an integer}, \text{or as } E = \{2x : x \in \mathbb{Z}\}. \quad \blacktriangle
\]

Also,

\[
S = \{x^2 : x \text{ is an integer}\} = \{x^2 : x \in \mathbb{Z}\} = \{0, 1, 4, 9, \ldots\}
\]

describes the set of squares of integers.

The set of real numbers is denoted by \( \mathbb{R} \) and the set of positive real numbers is denoted by \( \mathbb{R}^+ \). A real number that can be expressed in the form \( \frac{m}{n} \), where \( m, n \in \mathbb{Z} \) and \( n \neq 0 \), is called a rational number. For example, \( \frac{2}{3}, \frac{-5}{11}, 17 = \frac{17}{1} \) and \( \frac{4}{9} \) are rational numbers. Of course, \( \frac{2}{3} = \frac{4}{5} \). The set of all rational numbers is denoted by \( \mathbb{Q} \). A real number that is not rational is called irrational. The real numbers \( \sqrt{2}, \sqrt{3}, \sqrt{2}, \pi \) and \( e \) are known to be irrational; that is, none of these numbers can be expressed as the ratio of two integers. It is also known that the real numbers with (infinite) nonrepeating decimal expansions are precisely the irrational numbers. There is no common symbol to denote the set of irrational numbers. We will often use \( I \) for the set of all irrational numbers, however. Thus, \( \sqrt{2} \in \mathbb{R} \) and \( \sqrt{2} \notin \mathbb{Q} \); so \( \sqrt{2} \in \mathbb{I} \).

For a set \( S \), we write \( |S| \) to denote the number of elements in \( S \). The number \( |S| \) is also referred to as the cardinal number or cardinality of \( S \). If \( A = \{1, 2\} \) and \( B = \{1, 2, \{1, 2\}, \emptyset\} \), then \( |A| = 2 \) and \( |B| = 4 \). Also, \(|\emptyset| = 0 \). Although the notation is identical for the cardinality of a set and the absolute value of a real number, we should have no trouble distinguishing between the two. A set \( S \) is finite if \( |S| = n \) for some nonnegative integer \( n \). A set \( S \) is infinite if it is not finite. For the present, we will use the notation \( |S| \) only for finite sets \( S \). In Chapter 11, we will discuss the cardinality of infinite sets.

Let’s now consider a few examples of sets that are defined in terms of the special sets we have just described.

**Example 1.3** Let \( D = \{n \in \mathbb{N} : n \leq 9\} \), \( E = \{x \in \mathbb{Q} : x \leq 9\} \), \( H = \{x \in \mathbb{R} : x^2 - 2 = 0\} \) and \( J = \{x \in \mathbb{Q} : x^2 - 2 = 0\} \).

(a) Describe the set \( D \) by listing its elements.

(b) Give an example of three elements that belong to \( E \) but do not belong to \( D \).

(c) Describe the set \( H \) by listing its elements.
Section 1.1 Exercises

(d) Describe the set $J$ in another manner.
(e) Determine the cardinality of each set $D$, $H$, and $J$.

**Solution**

(a) $D = \{1, 2, 3, 4, 5, 6, 7, 8, 9\}$.
(b) $\frac{7}{3}, 0, -3$.
(c) $H = \{\sqrt{2}, -\sqrt{2}\}$.
(d) $J = \emptyset$.
(e) $|D| = 9$, $|H| = 2$ and $|J| = 0$.

♦

**Example 1.4**

In which of the following sets is the integer $-2$ an element?

$S_1 = \{-1, -2, \{-1\}, \{-2\}, \{-1, -2\}\}$, $S_2 = \{x \in \mathbb{N} : -x \in \mathbb{N}\}$,
$S_3 = \{x \in \mathbb{Z} : x^2 = 2^4\}$, $S_4 = \{x \in \mathbb{Z} : |x| = -x\}$,
$S_5 = \{\{-1, -2\}, \{-2, -3\}, \{-1, -3\}\}$.

**Solution**

The integer $-2$ is an element of the sets $S_1$ and $S_4$. For $S_4$, $|−2| = 2 = −(−2)$. The set $S_2 = \emptyset$. Since $(-2)^2 = 4$ and $2^{-2} = 1/4$, it follows that $−2 \not\in S_3$. Because each element of $S_5$ is a set, it contains no integers.

A **complex number** is a number of the form $a + bi$, where $a, b \in \mathbb{R}$ and $i = \sqrt{-1}$. A complex number $a + bi$, where $b = 0$, can be expressed as $a + 0i$ or, more simply, as $a$. Hence $a + 0i = a$ is a real number. Thus every real number is a complex number. Let $\mathbb{C}$ denote the set of complex numbers. If $K = \{x \in \mathbb{C} : x^2 + 1 = 0\}$, then $K = \{i, -i\}$. Of course, if $L = \{x \in \mathbb{R} : x^2 + 1 = 0\}$, then $L = \emptyset$. You might have seen that the sum of two complex numbers $a + bi$ and $c + di$ is $(a + c) + (b + d)i$, while their product is

$$(a + bi) \cdot (c + di) = ac + adi + bci + bdi^2 = (ac - bd) + (ad + bc)i.$$ 

The special sets that we’ve just described are now summarized below:

<table>
<thead>
<tr>
<th>Symbol</th>
<th>For the set of</th>

</tbody>
</table>

Real numbers and complex numbers are described in more detail in the online Chapter 18.

**SECTION 1.1 EXERCISES**

1.1. Which of the following are sets?

(a) 1, 2, 3  (b) \{1, 2\}, 3  (c) \{\{1\}, 2\}, 3
(d) \{1, \{2\}, 3\}  (e) \{1, 2, a, b\}.
18 Chapter 1 Sets

1.2 Let \( S = \{-2, -1, 0, 1, 2, 3\} \). Describe each of the following sets as \( \{x \in S : p(x)\} \), where \( p(x) \) is some condition on \( x \).
   (a) \( A = \{1, 2, 3\} \)
   (b) \( B = \{0, 1, 2, 3\} \)
   (c) \( C = \{-2, -1\} \)
   (d) \( D = \{-2, 2, 3\} \).

1.3 Determine the cardinality of each of the following sets:
   (a) \( A = \{1, 2, 3, 4, 5\} \)
   (b) \( B = \{0, 2, 4, \ldots, 20\} \)
   (c) \( C = \{25, 26, 27, \ldots, 75\} \)
   (d) \( D = \{1, 2, 3, 4\} \)
   (e) \( E = \{\emptyset\} \)
   (f) \( F = \{2, [2, 3, 4]\}\).

1.4 Write each of the following sets by listing its elements within braces.
   (a) \( A = \{n \in \mathbb{Z} : -4 < n \leq 4\} \)
   (b) \( B = \{n \in \mathbb{Z} : n^2 < 5\} \)
   (c) \( C = \{n \in \mathbb{N} : n^3 < 100\} \)
   (d) \( D = \{x \in \mathbb{R} : x^2 - x = 0\} \)
   (e) \( E = \{x \in \mathbb{R} : x^2 + 1 = 0\} \).

1.5 Write each of the following sets in the form \( \{x \in \mathbb{Z} : p(x)\} \), where \( p(x) \) is a property concerning \( x \).
   (a) \( A = \{-1, -2, -3, \ldots\} \)
   (b) \( B = \{-3, -2, \ldots, 3\} \)
   (c) \( C = \{-2, -1, 1, 2\} \).

1.6 The set \( E = \{2x : x \in \mathbb{Z}\} \) can be described by listing its elements, namely \( E = \{\ldots, -4, -2, 0, 2, 4, \ldots\} \). List the elements of the following sets in a similar manner.
   (a) \( A = \{2x + 1 : x \in \mathbb{Z}\} \)
   (b) \( B = \{4n : n \in \mathbb{Z}\} \)
   (c) \( C = \{3q + 1 : q \in \mathbb{Z}\} \).

1.7 The set \( E = \{\ldots, -4, -2, 0, 2, 4, \ldots\} \) of even integers can be described by means of a defining condition by \( E = \{y = 2x : x \in \mathbb{Z}\} = \{2x : x \in \mathbb{Z}\} \). Describe the following sets in a similar manner.
   (a) \( A = \{\ldots, -4, -1, 2, 5, 8, \ldots\} \)
   (b) \( B = \{\ldots, -10, -5, 0, 5, 10, \ldots\} \)
   (c) \( C = \{1, 8, 27, 64, 125, \ldots\} \).

1.8 Let \( A = \{n \in \mathbb{Z} : 2 \leq |n| < 4\} \), \( B = \{x \in \mathbb{Q} : 2 < x \leq 4\} \), \( C = \{x \in \mathbb{R} : x^2 - (2 + \sqrt{2})x + 2\sqrt{2} = 0\} \), and \( D = \{x \in \mathbb{Q} : x^2 = (2 + \sqrt{2})x + 2\sqrt{2} = 0\} \).
   (a) Describe the set \( A \) by listing its elements.
   (b) Give an example of three elements that belong to \( B \) but do not belong to \( A \).
   (c) Describe the set \( C \) by listing its elements.
   (d) Describe the set \( D \) in another manner.
   (e) Determine the cardinality of each of the sets \( A, C \) and \( D \).

1.9 For \( A = \{2, 3, 5, 7, 8, 10, 13\} \), let
   \[ B = \{x \in A : x = y + z, \text{ where } y, z \in A\} \]
   and \( C = \{r \in B : r + s \in B \text{ for some } s \in B\} \).

Determine \( C \).

1.2 SUBSETS

A set \( A \) is called a sub
subset of a set \( B \) if every element of \( A \) also belongs to \( B \). If \( A \) is a subset of \( B \), then we write \( A \subseteq B \). If \( A, B \) and \( C \) are sets such that \( A \subseteq B \) and \( B \subseteq C \), then \( A \subseteq C \). To see why this is so, suppose that some element \( x \) belongs to \( A \). Because \( A \subseteq B \), it follows that \( x \in B \). But \( B \subseteq C \), which implies that \( x \in C \). Therefore, every element that belongs to \( A \) also belongs to \( C \) and so \( A \subseteq C \). This property of subsets might remind you of the property of real numbers where if \( a, b, c \in \mathbb{R} \) such that if \( a \leq b \) and \( b \leq c \), then \( a \leq c \). For the sets \( X = \{1, 3, 6\} \) and \( Y = \{1, 2, 3, 5, 6\} \), we have \( X \subseteq Y \).
Also, \( N \subseteq Z \) and \( Q \subseteq R \). In addition, \( R \subseteq C \). Since \( Q \subseteq R \) and \( R \subseteq C \), it therefore follows that \( Q \subseteq C \). Moreover, every set is a subset of itself.

**Example 1.5** Find two sets \( A \) and \( B \) such that \( A \) is both an element of and a subset of \( B \).

**Solution** Suppose that we seek two sets \( A \) and \( B \) such that \( A \in B \) and \( A \subseteq B \). Let’s start with a simple example for \( A \), say \( A = \{1\} \). Since we want \( A \in B \), the set \( B \) must contain the set \( \{1\} \) as one of its elements. On the other hand, we also require that \( A \subseteq B \), so every element of \( A \) must belong to \( B \). Since 1 is the only element of \( A \), it follows that \( B \) must also contain the number 1. A possible choice for \( B \) is then \( B = \{1, \{1\}\} \), although \( B = \{1, 2, \{1\}\} \) would also satisfy the conditions.

In the following example, we will see how we arrive at the answer to a question asked there. This is a prelude to logic, which will be discussed in Chapter 2.

**Example 1.6** Two sets \( A \) and \( B \) have the property that each is a subset of \( \{1, 2, 3, 4, 5\} \) and \( |A| = |B| = 3 \). Furthermore,
- (a) 1 belongs to \( A \) but not to \( B \).
- (b) 2 belongs to \( B \) but not to \( A \).
- (c) 3 belongs to exactly one of \( A \) and \( B \).
- (d) 4 belongs to exactly one of \( A \) and \( B \).
- (e) 5 belongs to at least one of \( A \) and \( B \).

What are the possibilities for the set \( A \)?

**Solution** By (a) and (b), \( 1 \in A \) and \( 1 \notin B \), while \( 2 \in B \) and \( 2 \notin A \). By (c), 3 belongs to \( A \) or \( B \) but not both. By (d), 4 belongs to \( A \) or \( B \) but not both. If 3 and 4 belong to the same set, then either 3 and 4 both belong to \( A \) or 3 and 4 both belong to \( B \). Should it occur that 3 \( \in \) \( A \) and 4 \( \in \) \( A \), then 1 \( \notin \) \( B \), 3 \( \notin \) \( B \) and 4 \( \notin \) \( B \). This means that \( |B| \neq 3 \). On the other hand, if 3 \( \in \) \( B \) and 4 \( \in \) \( B \), then 3 \( \notin \) \( A \) and 4 \( \notin \) \( A \). Therefore, \( A \) contains none of 2, 3 and 4 and so \( |A| \neq 3 \). We can therefore conclude that 3 and 4 belong to different sets. The only way that \( |A| = |B| = 3 \) is for 5 to belong to both \( A \) and \( B \) and so either \( A = \{1, 3, 5\} \) or \( A = \{1, 4, 5\} \).

If a set \( C \) is not a subset of a set \( D \), then we write \( C \not\subseteq D \). In this case, there must be some element of \( C \) that is not an element of \( D \). One consequence of this is that the empty set \( \emptyset \) is a subset of every set. If this were not the case, then there must be some set \( A \) such that \( \emptyset \not\subseteq A \). But this would mean there is some element, say \( x \), in \( \emptyset \) that is not in \( A \). However, \( \emptyset \) contains no elements. So \( \emptyset \subseteq A \) for every set \( A \).

**Example 1.7** Let \( S = \{1, \{2\}, \{1, 2\}\} \).
- (a) Determine which of the following are elements of \( S \):
  - 1, \( \{1\} \), 2, \( \{2\} \), \( \{1, 2\} \), \( \{\{1, 2\}\} \).
- (b) Determine which of the following are subsets of \( S \):
  - \( \{1\} \), \( \{2\} \), \( \{1, 2\} \), \( \{\{1\}\} \), \( \{\{2\}\} \), \( \{\{1, 2\}\} \).
Chapter 1  Sets

Solution  

(a) The following are elements of S: 1, [2], {1, 2}.
(b) The following are subsets of S: {1}, {1, [2]}, {[1, 2]}. ♦

In a typical discussion of sets, we are ordinarily concerned with subsets of some specified set \( U \), called the universal set. For example, we may be dealing only with integers, in which case the universal set is \( \mathbb{Z} \), or we may be dealing only with real numbers, in which case the universal set is \( \mathbb{R} \). On the other hand, the universal set being considered may be neither \( \mathbb{Z} \) nor \( \mathbb{R} \). Indeed, \( U \) may not even be a set of numbers.

Some frequently encountered subsets of \( \mathbb{R} \) are the so-called “intervals,” which you have no doubt encountered often. For \( a, b \in \mathbb{R} \) and \( a < b \), the open interval \((a, b)\) is the set

\[ (a, b) = \{ x \in \mathbb{R} : a < x < b \}. \]

Therefore, all of the real numbers \( \sqrt{2}, \sqrt{5}, e, 3, \pi, 4, 99 \) belong to \((2, 5)\), but none of the real numbers \( \sqrt{2}, 1.99, 2, 5 \) belong to \((2, 5)\).

For \( a, b \in \mathbb{R} \) and \( a \leq b \), the closed interval \([a, b]\) is the set

\[ [a, b] = \{ x \in \mathbb{R} : a \leq x \leq b \}. \]

While \( 2, 5 \notin (2, 5) \), we do have \( 2, 5 \in [2, 5] \). The “interval” \([a, a]\) is therefore \([a]\). Thus, for \( a < b \), we have \((a, b) \subseteq [a, b]\). For \( a, b \in \mathbb{R} \) and \( a < b \), the half-open or half-closed intervals \([a, b)\) and \((a, b]\) are defined as expected:

\[ [a, b) = \{ x \in \mathbb{R} : a \leq x < b \} \quad \text{and} \quad (a, b] = \{ x \in \mathbb{R} : a < x \leq b \}. \]

For \( a \in \mathbb{R} \), the infinite intervals \((–\infty, a), (–\infty, a], (a, \infty)\) and \([a, \infty)\) are defined as

\[ (–\infty, a) = \{ x \in \mathbb{R} : x < a \}, \quad (–\infty, a] = \{ x \in \mathbb{R} : x \leq a \}, \]

\[ (a, \infty) = \{ x \in \mathbb{R} : x > a \}, \quad [a, \infty) = \{ x \in \mathbb{R} : x \geq a \}. \]

The interval \((–\infty, \infty)\) is the set \( \mathbb{R} \). Note that the infinity symbols \( \infty \) and \(-\infty\) are not real numbers; they are only used to help describe certain intervals. Therefore, \([1, \infty)\), for example, has no meaning.

Two sets \( A \) and \( B \) are equal, indicated by writing \( A = B \), if they have exactly the same elements. Another way of saying \( A = B \) is that every element of \( A \) is in \( B \) and every element of \( B \) is in \( A \), that is, \( A \subseteq B \) and \( B \subseteq A \). In particular, whenever some element \( x \) belongs to \( A \), then \( x \in B \) because \( A \subseteq B \). Also, if \( y \) is an element of \( B \), then because \( B \subseteq A \), it follows that \( y \in A \). That is, whenever an element belongs to one of these sets, it must belong to the other and so \( A = B \). This fact will be very useful to us in Chapter 4.

If \( A \neq B \), then there must be some element belonging to one of \( A \) and \( B \) that does not belong to the other.

It is often convenient to represent sets by diagrams called Venn diagrams. For example, Figure 1.1 shows Venn diagrams for two sets \( A \) and \( B \). The diagram on the left represents two sets \( A \) and \( B \) that have no elements in common, while the diagram on the right is more general. The element \( x \) belongs to \( A \) but not to \( B \), the element \( y \) belongs to \( B \) but not to \( A \), the element \( z \) belongs to both \( A \) and \( B \), while \( w \) belongs to neither \( A \) nor \( B \). In general, the elements of a set are understood to be those displayed within the region that describes the set. A rectangle in a Venn diagram represents the universal set.
in this case. Since every element under consideration belongs to the universal set, each element in a Venn diagram lies within the rectangle.

\[ A \quad \text{and} \quad B \]

\[ \begin{array}{c}
 A \\
 B \\
 \end{array} \]

\[ \begin{array}{c}
 x \\
 y \\
 z \\
 w \\
 \end{array} \]

\[ A \quad \text{and} \quad B \]

**Figure 1.1** Venn diagrams for two sets \( A \) and \( B \)

A set \( A \) is a **proper subset** of a set \( B \) if \( A \subseteq B \) but \( A \neq B \). If \( A \) is a proper subset of \( B \), then we write \( A \subset B \). For example, if \( S = \{4, 5, 7\} \) and \( T = \{3, 4, 5, 6, 7\} \), then \( S \subset T \). (Although we write \( A \subseteq B \) to indicate that \( A \) is a proper subset of \( B \), it should be mentioned that some prefer to write \( A \subset B \) to indicate that \( A \) is a proper subset of \( B \). Indeed, there are some who write \( A \subset B \) rather than \( A \subseteq B \), to indicate that \( A \) is a subset of \( B \). We will follow the notation introduced above, however.)

The set consisting of all subsets of a given set \( A \) is called the **power set** of \( A \) and is denoted by \( \mathcal{P}(A) \).

**Example 1.8** For each set \( A \) below, determine \( \mathcal{P}(A) \). In each case, determine \( |A| \) and \( |\mathcal{P}(A)| \).

\( A = \emptyset \), \( (b) \ A = \{a, b\} \), \( (c) \ A = \{1, 2, 3\} \).

**Solution**

\( (a) \ \mathcal{P}(A) = \{\emptyset\} \). In this case, \( |A| = 0 \) and \( |\mathcal{P}(A)| = 1 \).

\( (b) \ \mathcal{P}(A) = \{\emptyset, \{a\}, \{b\}, \{a, b\}\} \). In this case, \( |A| = 2 \) and \( |\mathcal{P}(A)| = 4 \).

\( (c) \ \mathcal{P}(A) = \{\emptyset, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}\} \).

In this case, \( |A| = 3 \) and \( |\mathcal{P}(A)| = 8 \).

Notice that for each set \( A \) in Example 1.8, we have \( |\mathcal{P}(A)| = 2^{|A|} \). In fact, if \( A \) is any finite set, with \( n \) elements say, then \( \mathcal{P}(A) \) has \( 2^n \) elements; that is,

\[ |\mathcal{P}(A)| = 2^{|A|} \]

for every finite set \( A \). (Later we will explain why this is true.)

**Example 1.9** If \( C = \{\emptyset, \{\emptyset\}\} \), then

\[ \mathcal{P}(C) = \{\emptyset, \{\emptyset\}, \{\emptyset, \{\emptyset\}\}\} \].

It is important to note that no two of the sets \( \emptyset, \{\emptyset\} \) and \( \{\emptyset, \{\emptyset\}\} \) are equal. (An empty box and a box containing an empty box are not the same.) For the set \( C \) above, it is therefore correct to write

\( \emptyset \subseteq C, \emptyset \subset C, \emptyset \in C, \{\emptyset\} \subseteq C, \{\emptyset\} \subset C, \emptyset \not\in C, \{\emptyset\} \not\in C \),

as well as

\[ \{\emptyset,\} \not\subseteq C, \{\emptyset\} \not\in C, \{\emptyset\} \not\in \mathcal{P}(C) \].

\[ \emptyset \subseteq C, \emptyset \subset C, \emptyset \in C, \{\emptyset\} \subseteq C, \{\emptyset\} \subset C, \emptyset \not\in C \].
CHAPTER 1  Sets

SECTION 1.2 EXERCISES

1.10. Give examples of three sets $A$, $B$ and $C$ such that
   
   (a) $A \subseteq B \subset C$
   
   (b) $A \in B$, $B \in C$ and $A \notin C$
   
   (c) $A \in B$ and $A \subset C$.

1.11. Let $(a, b)$ be an open interval of real numbers and let $c \in (a, b)$. Describe an open interval $I$ centered at $c$ such that $I \subseteq (a, b)$.

1.12. Which of the following sets are equal?
   
   $A = \{n \in \mathbb{Z} : |n| < 2\}$  $D = \{n \in \mathbb{Z} : n^2 \leq 1\}$
   
   $B = \{n \in \mathbb{Z} : n^3 = n\}$  $E = \{-1, 0, 1\}$.
   
   $C = \{n \in \mathbb{Z} : n^2 \leq n\}$

1.13. For a universal set $U = \{1, 2, \ldots, 8\}$ and two sets $A = \{1, 3, 4, 7\}$ and $B = \{4, 5, 8\}$, draw a Venn diagram that represents these sets.

1.14. Find $\mathcal{P}(A)$ and $|\mathcal{P}(A)|$ for
   
   (a) $A = \{1, 2\}$  (b) $A = \{\emptyset, 1, \{a\}\}$.

1.15. Find $\mathcal{P}(A)$ for $A = \{0, \{0\}\}$.

1.16. Find $\mathcal{P}(\mathcal{P}(\{1\}))$ and its cardinality.

1.17. Find $\mathcal{P}(A)$ and $|\mathcal{P}(A)|$ for $A = \{0, \emptyset, \{\emptyset\}\}$.

1.18. For $A = \{x : x = 0 \text{ or } x \in \mathcal{P}(\{0\})\}$, determine $\mathcal{P}(A)$.

1.19. Give an example of a set $S$ such that
   
   (a) $S \subseteq \mathcal{P}(\mathbb{N})$  (b) $S \in \mathcal{P}(\mathbb{N})$
   
   (c) $S \subseteq \mathcal{P}(\mathbb{N})$ and $|S| = 5$  (d) $S \in \mathcal{P}(\mathbb{N})$ and $|S| = 5$.

1.20. Determine whether the following statements are true or false.
   
   (a) If $\{1\} \in \mathcal{P}(A)$, then $1 \in A$ but $\{1\} \notin A$.
   
   (b) If $A$, $B$ and $C$ are sets such that $A \subseteq \mathcal{P}(B) \subset C$ and $|A| = 2$, then $|C|$ can be 5 but $|C|$ cannot be 4.
   
   (c) If a set $B$ has one more element than a set $A$, then $\mathcal{P}(B)$ has at least two more elements than $\mathcal{P}(A)$.
   
   (d) If four sets $A$, $B$, $C$ and $D$ are subsets of $\{1, 2, 3\}$ such that $|A| = |B| = |C| = |D| = 2$, then at least two of these sets are equal.

1.21. Three subsets $A$, $B$ and $C$ of $\{1, 2, 3, 4, 5\}$ have the same cardinality. Furthermore,
   
   (a) 1 belongs to $A$ and $B$ but not to $C$.
   
   (b) 2 belongs to $A$ and $C$ but not to $B$.
   
   (c) 3 belongs to $A$ and exactly one of $B$ and $C$.
   
   (d) 4 belongs to an even number of $A$, $B$ and $C$.
   
   (e) 5 belongs to an odd number of $A$, $B$ and $C$.
   
   (f) The sums of the elements in two of the sets $A$, $B$ and $C$ differ by 1.

   What is $B$?
1.3 SET OPERATIONS

Just as there are several ways of combining two integers to produce another integer (addition, subtraction, multiplication and sometimes division), there are several ways to combine two sets to produce another set. The union of two sets \( A \) and \( B \), denoted by \( A \cup B \), is the set of all elements belonging to \( A \) or \( B \), that is,
\[
A \cup B = \{ x : x \in A \text{ or } x \in B \}.
\]
The use of the word “or” here, and in mathematics in general, allows an element of \( A \cup B \) to belong to both \( A \) and \( B \). That is, \( x \) is in \( A \cup B \) if \( x \) is in \( A \), or \( x \) is in \( B \), or \( x \) is in both \( A \) and \( B \). A Venn diagram for \( A \cup B \) is shown in Figure 1.2. The shaded region indicates the set \( A \cup B \).

![Venn diagram for \( A \cup B \)](image)

**Figure 1.2**  A Venn diagram for \( A \cup B \)

**Example 1.10**  For the sets \( A_1 = \{2, 5, 7, 8\}, A_2 = \{1, 3, 5\} \) and \( A_3 = \{2, 4, 6, 8\} \), we have
\[
A_1 \cup A_2 = \{1, 2, 3, 5, 7, 8\},
\]
\[
A_1 \cup A_3 = \{2, 4, 5, 6, 7, 8\},
\]
\[
A_2 \cup A_3 = \{1, 2, 3, 4, 5, 6, 8\}.
\]
Also, \( \mathbb{N} \cup \mathbb{Z} = \mathbb{Z} \) and \( \mathbb{Q} \cup \mathbb{I} = \mathbb{R} \).

The intersection of two sets \( A \) and \( B \) is the set of all elements belonging to both \( A \) and \( B \). The intersection of \( A \) and \( B \) is denoted by \( A \cap B \). In symbols,
\[
A \cap B = \{ x : x \in A \text{ and } x \in B \}.
\]
A Venn diagram for \( A \cap B \) is shown in Figure 1.3, again indicated by the shaded region.

![Venn diagram for \( A \cap B \)](image)

**Figure 1.3**  A Venn diagram for \( A \cap B \)
Chapter 1  Sets

Example 1.11 For the sets $A_1, A_2$ and $A_3$ described in Example 1.10,

$$A_1 \cap A_2 = \{5\}, A_1 \cap A_3 = \{2, 8\} \text{ and } A_2 \cap A_3 = \emptyset.$$  

Also, $N \cap Z = N$ and $Q \cap R = Q$. 

For every two sets $A$ and $B$, it follows that

$$A \cap B \subseteq A \cup B.$$ 

To see why this is true, suppose that $x$ is an element belonging to $A \cap B$. Then $x$ belongs to both $A$ and $B$. Since $x \in A$, for example, $x \in A \cup B$ and so $A \cap B \subseteq A \cup B$.

If two sets $A$ and $B$ have no elements in common, then $A \cap B = \emptyset$ and $A$ and $B$ are said to be disjoint. Consequently, the sets $A_2$ and $A_3$ described in Example 1.10 are disjoint; however, $A_1$ and $A_3$ are not disjoint since 2 and 8 belong to both sets. Also, $Q$ and $I$ are disjoint.

The difference $A \setminus B$ of two sets $A$ and $B$ (also written as $A \setminus B$ by some mathematicians) is defined as

$$A \setminus B = \{ x : x \in A \text{ and } x \notin B \}.$$ 

A Venn diagram for $A \setminus B$ is shown in Figure 1.4.

![Venn diagram](image)

Figure 1.4  A Venn diagram for $A \setminus B$

Example 1.12 For the sets $A_1 = \{2, 5, 7, 8\}$ and $A_2 = \{1, 3, 5\}$ in Examples 1.10 and 1.11, $A_1 - A_2 = \{2, 7, 8\}$ and $A_2 - A_1 = \{1, 3\}$. Furthermore, $R - Q = I$. 

Example 1.13 Let $A = \{x \in R : |x| \leq 3\}, B = \{x \in R : |x| > 2\}$ and $C = \{x \in R : |x - 1| \leq 4\}$.

(a) Express $A, B$ and $C$ using interval notation.

(b) Determine $A \cap B, A - B, B \cap C, B \cup C, B - C$ and $C - B$.

Solution

(a) $A = [-3, 3], B = (-\infty, -2) \cup (2, \infty)$ and $C = [-3, 5]$. 

(b) $A \cap B = [-3, -2) \cup (2, 3], A - B = [-2, 2], B \cap C = [-3, -2) \cup (2, 5], B \cup C = (-\infty, \infty), B - C = (-\infty, -3) \cup (5, \infty)$ and $C - B = [-2, 2]$. 

Suppose that we are considering a certain universal set $U$, that is, all sets being discussed are subsets of $U$. For a set $A$, its complement is

$$\overline{A} = U - A = \{ x : x \in U \text{ and } x \notin A \}.$$
1.3 Set Operations

If \( U = \mathbb{Z} \), then \( \overline{\mathbb{N}} = \{0, -1, -2, \ldots\} \); while if \( U = \mathbb{R} \), then \( \overline{\mathbb{Q}} = \mathbb{I} \). A Venn diagram for \( \overline{A} \) is shown in Figure 1.5.

![Venn diagram for \( \overline{A} \)](image)

Figure 1.5 A Venn diagram for \( \overline{A} \)

The set difference \( A - B \) is sometimes called the relative complement of \( B \) in \( A \). Indeed, from the definition, \( A - B = \{ x : x \in A \text{ and } x \notin B \} \). The set \( A - B \) can also be expressed in terms of complements, namely, \( A - B = A \cap \overline{B} \). This fact will be established later.

**Example 1.14** Let \( U = \{1, 2, \ldots, 10\} \) be the universal set, \( A = \{2, 3, 5, 7\} \) and \( B = \{2, 4, 6, 8, 10\} \). Determine each of the following:

(a) \( \overline{B} \),
(b) \( A - B \),
(c) \( A \cap \overline{B} \),
(d) \( \overline{\overline{B}} \).

**Solution**

(a) \( \overline{B} = \{1, 3, 5, 7, 9\} \).
(b) \( A - B = \{3, 5, 7\} \).
(c) \( A \cap \overline{B} = \{3, 5, 7\} = A - B \).
(d) \( \overline{\overline{B}} = B = \{2, 4, 6, 8, 10\} \).

**Example 1.15** Let \( A = \{0, \{0\}, \{0, \{0\}\}\} \).

(a) Determine which of the following are elements of \( A \): \( \{0\}, \{\{0\}\}, \{0, \{0\}\} \).
(b) Determine \( |A| \).
(c) Determine which of the following are subsets of \( A \): \( \{0\}, \{\{0\}\}, \{0, \{0\}\} \).

For (d)–(i), determine the indicated sets.

(d) \( \{0\} \cap A \)
(e) \( \{\{0\}\} \cap A \)
(f) \( \{\{0\}\} \cap A \)
(g) \( \{0\} \cup A \)
(h) \( \{\{0\}\} \cup A \)
(i) \( \{\{0\}\} \cup A \).
26 Chapter 1 Sets

Solution

(a) While 0 and \{0\} are elements of \(A\), \{\{0\}\} is not an element of \(A\).
(b) The set \(A\) has three elements: 0, \{0\}, \{0, \{0\}\}. Therefore, \(|A| = 3\).
(c) The integer 0 is not a set and so cannot be a subset of \(A\) (or a subset of any other set). Since 0 \(\in A\) and \{0\} \(\in A\), it follows that \{0\} \(\subseteq A\) and \{\{0\}\} \(\subseteq A\).
(d) Since 0 is the only element that belongs to both \{0\} and \(A\), it follows that \{0\} \(\cap A = \{0\}\).
(e) Since \{0\} is the only element that belongs to both \{\{0\}\} and \(A\), it follows that \{\{0\}\} \(\cap A = \{0\}\).
(f) Since \{\{0\}\} is not an element of \(A\), it follows that \{\{\{0\}\}\} \(\cap A = \{0\}\). 
(g) Since 0 \(\in A\), it follows that \{0\} \(\cup A = A\).
(h) Since \{0\} \(\in A\), it follows that \{\{0\}\} \(\cup A = A\).
(i) Since \{\{0\}\} \(\not\in A\), it follows that \{\{\{0\}\}\} \(\cup A = \{0, \{0\}, \{\{0\}\}, \{0, \{0\}\}\}\).

SECTION 1.3 EXERCISES

1.22. Let \(U = \{1, 3, \ldots, 15\}\) be the universal set, \(A = \{1, 5, 9, 13\}\) and \(B = \{3, 9, 15\}\). Determine the following:
   (a) \(A \cup B\)  (b) \(A \cap B\)  (c) \(A - B\)  (d) \(B - A\)  (e) \(\overline{A}\)  (f) \(A \cap \overline{B}\).

1.23. Give examples of two sets \(A\) and \(B\) such that \(|A - B| = |A \cap B| = |B - A| = 3\). Draw the accompanying Venn diagram.

1.24. Give examples of three sets \(A, B\) and \(C\) such that \(B \neq C\) but \(B - A = C - A\).

1.25. Give examples of three sets \(A, B\) and \(C\) such that
   (a) \(A \in B, A \subseteq C\) and \(B \not\subseteq C\)
   (b) \(B \in A, B \subseteq C\) and \(A \cap C \neq \emptyset\)
   (c) \(A \in B, B \subseteq C\) and \(A \not\subseteq C\).

1.26. Let \(U\) be a universal set and let \(A\) and \(B\) be two subsets of \(U\). Draw a Venn diagram for each of the following sets.
   (a) \(\overline{A \cup B}\)  (b) \(\overline{A \cap B}\)  (c) \(\overline{A \cap \overline{B}}\)  (d) \(\overline{A \cup \overline{B}}\).
   What can you say about parts (a) and (b)? parts (c) and (d)?

1.27. Give an example of a universal set \(U\), two sets \(A\) and \(B\) and accompanying Venn diagram such that \(|A \cap B| = |A - B| = |B - A| = |A \cup B| = 2\).

1.28. Let \(A, B\) and \(C\) be nonempty subsets of a universal set \(U\). Draw a Venn diagram for each of the following set operations.
   (a) \((C - B) \cup A\)  (b) \(C \cap (A - B)\).

1.29. Let \(A = \{\emptyset, \{\emptyset\}, \{\{\emptyset\}\}\}\).
   (a) Determine which of the following are elements of \(A\): \(\emptyset, \{\emptyset\}, \{\{\emptyset\}\}\).
   (b) Determine \(|A|\).
   (c) Determine which of the following are subsets of \(A\): \(\emptyset, \{\emptyset\}, \{\{\emptyset\}\}\).
   For (d)–(i), determine the indicated sets.
   (d) \(\emptyset \cap A\)  (e) \(\{\emptyset\} \cap A\)  (f) \(\{\emptyset\} \cap \{\emptyset\}\) \(\cap A\)
   (g) \(\emptyset \cup A\)  (h) \(\{\emptyset\} \cup A\)  (i) \(\{\emptyset, \{\emptyset\}\} \cup A\).
1.30. Let \( A = \{ x \in \mathbb{R} : |x - 1| \leq 2 \} \), \( B = \{ x \in \mathbb{R} : |x| \geq 1 \} \) and \( C = \{ x \in \mathbb{R} : |x + 2| \leq 3 \} \).

(a) Express \( A \), \( B \) and \( C \) using interval notation.

(b) Determine each of the following sets using interval notation:
\[ A \cup B, A \cap B, B \cap C, B - C. \]

1.31. Give an example of four different sets \( A, B, C \) and \( D \) such that (1) \( A \cup B = \{1, 2\} \) and \( C \cap D = \{2, 3\} \) and (2) if \( B \) and \( C \) are interchanged and \( \cup \) and \( \cap \) are interchanged, then we get the same result.

1.32. Give an example of four different subsets \( A, B, C \) and \( D \) of \( \{1, 2, 3, 4\} \) such that all intersections of two subsets are different.

1.33. Give an example of two nonempty sets \( A \) and \( B \) such that \( \{ A \cup B, A \cap B, A - B, B - A \} \) is the power set of some set.

1.34. Give an example of two subsets \( A \) and \( B \) of \( \{1, 2, 3\} \) such that all of the following sets are different: \( A \cup B, A \cup \overline{B}, \overline{A} \cup B, \overline{A} \cup \overline{B}, A \cap B, A \cap \overline{B}, \overline{A} \cap B, \overline{A} \cap \overline{B}. \)

1.35. Give examples of a universal set \( U \) and sets \( A, B \) and \( C \) such that each of the following sets contains exactly one element: \( A \cap B \cap C, (A \cap B) - C, (A \cap C) - B, (B \cap C) - A, A - (B \cup C), B - (A \cup C), C - (A \cup B), A \cup B \cup \overline{C}. \) Draw the accompanying Venn diagram.

### 1.4 Indexed Collections of Sets

We will often encounter situations where more than two sets are combined using the set operations described earlier. In the case of three sets \( A, B \) and \( C \), the standard Venn diagram is shown in Figure 1.6.

![Venn diagram for three sets](image)

**Figure 1.6** A Venn diagram for three sets

The union \( A \cup B \cup C \) is defined as
\[ A \cup B \cup C = \{ x : x \in A, \text{ or } x \in B, \text{ or } x \in C \}. \]

Thus, in order for an element to belong to \( A \cup B \cup C \), the element must belong to at least one of the sets \( A, B \) and \( C \). Because it is often useful to consider the union of several sets, additional notation is needed. The union of the \( n \geq 2 \) sets \( A_1, A_2, \ldots, A_n \) is denoted by \( A_1 \cup A_2 \cup \cdots \cup A_n \) or \( \bigcup_{i=1}^{n} A_i \) and is defined as
\[ \bigcup_{i=1}^{n} A_i = \{ x : x \in A_i \text{ for some } i, 1 \leq i \leq n \}. \]
Chapter 1  Sets

Thus, for an element $a$ to belong to $\bigcup_{i=1}^{n} A_i$, it is necessary that $a$ belongs to at least one of the sets $A_1, A_2, \ldots, A_n$.

**Example 1.16**  Let $B_1 = \{1, 2\}$, $B_2 = \{2, 3\}$, $\ldots$, $B_{10} = \{10, 11\}$; that is, $B_i = \{i, i + 1\}$ for $i = 1, 2, \ldots, 10$. Determine each of the following:

(a) $\bigcup_{i=1}^{5} B_i$.  (b) $\bigcup_{i=1}^{10} B_i$.  (c) $\bigcup_{i=3}^{7} B_i$.  (d) $\bigcup_{i=j}^{k} B_i$, where $1 \leq j \leq k \leq 10$.

**Solution**

(a) $\bigcup_{i=1}^{5} B_i = \{1, 2, \ldots, 6\}$.  (b) $\bigcup_{i=1}^{10} B_i = \{1, 2, \ldots, 11\}$.

(c) $\bigcup_{i=3}^{7} B_i = \{3, 4, \ldots, 8\}$.  (d) $\bigcup_{i=j}^{k} B_i = \{j, j + 1, \ldots, k + 1\}$.

We are often interested in the intersection of several sets as well. The intersection of the $n \geq 2$ sets $A_1, A_2, \ldots, A_n$ is expressed as $A_1 \cap A_2 \cap \cdots \cap A_n$ or $\bigcap_{i=1}^{n} A_i$ and is defined by

$$\bigcap_{i=1}^{n} A_i = \{x : x \in A_i \text{ for every } i, 1 \leq i \leq n\}.$$  

The next example concerns the sets mentioned in Example 1.16.

**Example 1.17**  Let $B_i = \{i, i + 1\}$ for $i = 1, 2, \ldots, 10$. Determine the following:

(a) $\bigcap_{i=1}^{10} B_i$.  (b) $B_i \cap B_{i+1}$.  (c) $\bigcap_{i=j}^{j+1} B_i$, where $1 \leq j < 10$.

(d) $\bigcap_{i=j}^{k} B_i$ where $1 \leq j < k \leq 10$.

**Solution**

(a) $\bigcap_{i=1}^{10} B_i = \emptyset$.  (b) $B_i \cap B_{i+1} = \{i + 1\}$.  (c) $\bigcap_{i=j}^{j+1} B_i = \{j + 1\}$.

(d) $\bigcap_{i=j}^{k} B_i = \{j + 1\}$ if $k = j + 1$; while $\bigcap_{i=j}^{k} B_i = \emptyset$ if $k > j + 1$.

There are instances when the union or intersection of a collection of sets cannot be described conveniently (or perhaps at all) in the manner mentioned above. For this reason, we introduce a (nonempty) set $I$, called an index set, which is used as a mechanism for selecting those sets we want to consider. For example, for an index set $I$, suppose that there is a set $S_\alpha$ for each $\alpha \in I$. We write $\{S_\alpha\}_{\alpha \in I}$ to describe the collection of all sets $S_\alpha$ where $\alpha \in I$. Such a collection is called an indexed collection of sets. We define the
union of the sets in $\{S_\alpha\}_{\alpha \in I}$ by
\[
\bigcup_{\alpha \in I} S_\alpha = \{x : x \in S_\alpha \text{ for some } \alpha \in I\},
\]
and the intersection of these sets by
\[
\bigcap_{\alpha \in I} S_\alpha = \{x : x \in S_\alpha \text{ for all } \alpha \in I\}.
\]
Hence, an element $a$ belongs to $\bigcup_{\alpha \in I} S_\alpha$ if $a$ belongs to at least one of the sets in the collection $\{S_\alpha\}_{\alpha \in I}$; while $a$ belongs to $\bigcap_{\alpha \in I} S_\alpha$ if $a$ belongs to every set in the collection $\{S_\alpha\}_{\alpha \in I}$. We refer to $\bigcup_{\alpha \in I} S_\alpha$ as the union of the collection $\{S_\alpha\}_{\alpha \in I}$ and $\bigcap_{\alpha \in I} S_\alpha$ as the intersection of the collection $\{S_\alpha\}_{\alpha \in I}$. Just as there is nothing special about our choice of $i$ in $\bigcup_{i=1}^n A_i$ (that is, we could just as well describe this set by $\bigcup_{j=1}^p A_j$, say), there is nothing special about $\alpha$ in $\bigcup_{\alpha \in I} S_\alpha$. We could also describe this set by $\bigcup_{\alpha \in I} S_\alpha$. The variables $i$ and $\alpha$ above are “dummy variables” and any appropriate symbol could be used. Indeed, we could write $J$ or some other symbol for an index set.

**Example 1.18**  For $n \in \mathbb{N}$, define $S_n = \{n, 2n\}$. For example, $S_1 = \{1, 2\}$, $S_2 = \{2, 4\}$ and $S_4 = \{4, 8\}$. Then $S_1 \cup S_2 \cup S_4 = \{1, 2, 4, 8\}$. We can also describe this set by means of an index set. If we let $I = \{1, 2, 4\}$, then
\[
\bigcup_{\alpha \in I} S_\alpha = S_1 \cup S_2 \cup S_4.
\]

**Example 1.19**  For each $n \in \mathbb{N}$, define $A_n$ to be the closed interval $[-\frac{1}{n}, \frac{1}{n}]$ of real numbers; that is,
\[
A_n = \left\{ x \in \mathbb{R} : -\frac{1}{n} \leq x \leq \frac{1}{n} \right\}.
\]
So $A_1 = [-1, 1]$, $A_2 = [-\frac{1}{2}, \frac{1}{2}]$, $A_3 = [-\frac{1}{3}, \frac{1}{3}]$ and so on. We have now defined the sets $A_1, A_2, A_3, \ldots$. The union of these sets can be written as $A_1 \cup A_2 \cup A_3 \cup \cdots$ or $\bigcup_{i=1}^\infty A_i$. Using $\mathbb{N}$ as an index set, we can also write this union as $\bigcup_{n \in \mathbb{N}} A_n$. Since $A_n \subseteq A_1 = [-1, 1]$ for every $n \in \mathbb{N}$, it follows that $\bigcup_{n \in \mathbb{N}} A_n = [-1, 1]$. Certainly, $0 \in A_n$ for every $n \in \mathbb{N}$; in fact, $\bigcap_{n \in \mathbb{N}} A_n = \{0\}$.

**Example 1.20**  Let $A$ denote the set of the letters of the alphabet, that is, $A = \{a, b, \ldots, z\}$. For $\alpha \in A$, let $A_\alpha$ consist of $\alpha$ and the two letters that follow $\alpha$. So $A_a = \{a, b, c\}$ and $A_b = \{b, c, d\}$. By $A_\alpha$, we will mean the set $\{\gamma, z, a\}$ and $A_z = \{z, a, b\}$. Hence $|A_\alpha| = 3$ for every $\alpha \in A$. Therefore, $\bigcup_{\alpha \in A} A_\alpha = A$. Indeed, if
\[
B = \{a, d, g, j, m, p, s, v, y\},
\]
then $\bigcup_{\alpha \in B} A_\alpha = A$ as well. On the other hand, if $I = \{p, q, r\}$, then $\bigcup_{\alpha \in I} A_\alpha = \{p, q, r, s, t\}$ while $\bigcap_{\alpha \in I} A_\alpha = \{r\}$.

**Example 1.21**  Let $S = \{1, 2, \ldots, 10\}$. Each of the sets
\[
S_1 = \{1, 2, 3, 4\}, S_2 = \{4, 5, 6, 7, 8\} \text{ and } S_3 = \{7, 8, 9, 10\}\]
30 Chapter 1 Sets

is a subset of $S$. Also, $S_1 \cup S_2 \cup S_3 = S$. This union can be described in a number of ways. Define $I = \{1, 2, 3\}$ and $J = \{S_1, S_2, S_3\}$. Then the union of the three sets belonging to $J$ is precisely $S_1 \cup S_2 \cup S_3$, which can also be written as

$$S = S_1 \cup S_2 \cup S_3 = \bigcup_{i=1}^{3} S_i = \bigcup_{a \in I} S_a = \bigcup_{X \in I} X.$$  

SECTION 1.4 EXERCISES

1.36. For a real number $r$, define $S_r$ to be the interval $[r - 1, r + 2]$. Let $A = \{1, 3, 4\}$. Determine $\bigcup_{a \in A} S_a$ and $\bigcap_{a \in A} S_a$.

1.37. Let $A = \{1, 2, 5\}, B = \{0, 2, 4\}, C = \{2, 3, 4\}$ and $S = \{A, B, C\}$. Determine $\bigcup_{X \in S} X$ and $\bigcap_{X \in S} X$.

1.38. For a real number $r$, define $A_r = \{r^2\}$, $B_r$ as the closed interval $[r - 1, r + 1]$ and $C_r$ as the interval $(r, \infty)$. For $S = \{1, 2, 4\}$, determine

(a) $\bigcup_{a \in S} A_a$ and $\bigcap_{a \in S} A_a$
(b) $\bigcup_{a \in S} B_a$ and $\bigcap_{a \in S} B_a$
(c) $\bigcup_{a \in S} C_a$ and $\bigcap_{a \in S} C_a$.

1.39. Let $A = \{a, b, \ldots, z\}$ be the set consisting of the letters of the alphabet. For $\alpha \in A$, let $A_\alpha$ consist of $\alpha$ and the two letters that follow it, where $A_y = \{y, z, a\}$ and $A_z = \{z, a, b\}$. Find a set $S \subseteq A$ of smallest cardinality such that $\bigcup_{\alpha \in S} A_\alpha = A$. Explain why your set $S$ has the required properties.

1.40. For $i \in \mathbb{Z}$, let $A_i = \{i - 1, i + 1\}$. Determine the following:

(a) $\bigcup_{i=1}^{5} A_{2i}$
(b) $\bigcup_{i=1}^{5} (A_i \cap A_{i+1})$
(c) $\bigcup_{i=1}^{5} (A_{2i-1} \cap A_{2i+1})$.

1.41. For each of the following, find an indexed collection $\{A_n\}_{n \in \mathbb{N}}$ of distinct sets (that is, no two sets are equal) satisfying the given conditions.

(a) $\bigcap_{n=1}^{\infty} A_n = \{0\}$ and $\bigcup_{n=1}^{\infty} A_n = [0, 1]$
(b) $\bigcap_{n=1}^{\infty} A_n = \{-1, 0, 1\}$ and $\bigcup_{n=1}^{\infty} A_n = \mathbb{Z}$.

1.42. For each of the following collections of sets, define a set $A_n$ for each $n \in \mathbb{N}$ such that the indexed collection $\{A_n\}_{n \in \mathbb{N}}$ is precisely the given collection of sets. Then find both the union and intersection of the indexed collection of sets.

(a) $\{(1, 2 + 1), [1, 2 + 1/2), [1, 2 + 1/3), \ldots\}$
(b) $\{(-1, 2), (-3/2, 4), (-5/3, 6), (-7/4, 8), \ldots\}$

1.43. For $r \in \mathbb{R}^+$, let $A_r = \{x \in \mathbb{R} : |x| < r\}$. Determine $\bigcup_{r \in \mathbb{R}^+} A_r$ and $\bigcap_{r \in \mathbb{R}^+} A_r$.

1.44. Each of the following sets is a subset of $A = \{1, 2, \ldots, 10\}$:

$A_1 = \{1, 5, 7, 9, 10\}, A_2 = \{1, 2, 3, 8, 9\}, A_3 = \{2, 4, 6, 8, 9\},$
$A_4 = \{2, 4, 8\}, A_5 = \{3, 6, 7\}, A_6 = \{3, 8, 10\}, A_7 = \{4, 5, 7, 9\},$
$A_8 = \{4, 5, 10\}, A_9 = \{4, 6, 8\}, A_{10} = \{5, 6, 10\},$
$A_{11} = \{5, 8, 9\}, A_{12} = \{6, 7, 10\}, A_{13} = \{6, 8, 9\}.$

Find a set $I \subseteq \{1, 2, \ldots, 13\}$ such that for every two distinct elements $j, k \in I$, $A_j \cap A_k = \emptyset$ and $|\bigcup_{i \in I} A_i|$ is maximum.

1.45. For $n \in \mathbb{N}$, let $A_n = (\frac{-1}{n}, 2 - \frac{1}{n})$. Determine $\bigcup_{n \in \mathbb{N}} A_n$ and $\bigcap_{n \in \mathbb{N}} A_n$. 
1.46. Determine the following:

(a) \( \bigcup_{n=1}^{\infty} \left( \frac{-1}{n}, \frac{1}{n} \right) \) and \( \bigcap_{n=1}^{\infty} \left( \frac{-1}{n}, \frac{1}{n} \right) \)

(b) \( \bigcup_{n=1}^{\infty} \left[ \frac{n-1}{n}, \frac{n+1}{n} \right] \) and \( \bigcap_{n=1}^{\infty} \left[ \frac{n-1}{n}, \frac{n+1}{n} \right] \)

1.47. Determine the following:

(a) \( \bigcup_{n=1}^{\infty} \left\{ \sin^2 \frac{n\pi}{2} + \cos^2 \frac{n\pi}{2} \right\} \) and \( \bigcap_{n=1}^{\infty} \left\{ \sin^2 \frac{n\pi}{2} + \cos^2 \frac{n\pi}{2} \right\} \)

(b) \( \bigcup_{n=1}^{\infty} \left\{ \sin \frac{n\pi}{2} + \cos \frac{n\pi}{2} \right\} \) and \( \bigcap_{n=1}^{\infty} \left\{ \sin \frac{n\pi}{2} + \cos \frac{n\pi}{2} \right\} \)

### 1.5 PARTITIONS OF SETS

Recall that two sets are disjoint if their intersection is the empty set. A collection \( S \) of subsets of a set \( A \) is called pairwise disjoint if every two distinct subsets that belong to \( S \) are disjoint. For example, let \( A = \{1, 2, \ldots, 7\} \), \( B = \{1, 6\} \), \( C = \{2, 5\} \), \( D = \{4, 7\} \) and \( S = \{B, C, D\} \). Then \( S \) is a pairwise disjoint collection of subsets of \( A \) since \( B \cap C = B \cap D = C \cap D = \emptyset \). On the other hand, let \( A' = \{1, 2, 3\} \), \( B' = \{1, 2\} \), \( C' = \{1, 3\} \), \( D' = \{2, 3\} \) and \( S' = \{B', C', D'\} \). Although \( S' \) is a collection of subsets of \( A' \) and \( B' \cap C' \cap D' = \emptyset \), the set \( S' \) is not a pairwise disjoint collection of sets since \( B' \cap C' \neq \emptyset \), for example. Indeed, \( B' \cap D' \) and \( C' \cap D' \) are also nonempty.

We will often have the occasion (especially in Chapter 9) to encounter, for a nonempty set \( A \), a collection \( S \) of pairwise disjoint nonempty subsets of \( A \) with the added property that every element of \( A \) belongs to some subset in \( S \). Such a collection is called a **partition** of \( A \). A partition of \( A \) can also be defined as a collection \( S \) of nonempty subsets of \( A \) such that every element of \( A \) belongs to exactly one subset in \( S \). Furthermore, a partition of \( A \) can be defined as a collection \( S \) of subsets of \( A \) satisfying the three properties:

1. \( X \neq \emptyset \) for every set \( X \in S \);
2. for every two sets \( X, Y \in S \), either \( X = Y \) or \( X \cap Y = \emptyset \);
3. \( \bigcup_{X \in S} X = A \).

**Example 1.22** Consider the following collections of subsets of the set \( A = \{1, 2, 3, 4, 5, 6\} \):

\[
S_1 = \{\{1, 3, 6\}, \{2, 4\}, \{5\}\};
\]

\[
S_2 = \{\{1, 2, 3\}, \{4\}, \emptyset, \{5, 6\}\};
\]

\[
S_3 = \{\{1, 2\}, \{3, 4, 5\}, \{5, 6\}\};
\]

\[
S_4 = \{\{1, 4\}, \{3, 5\}, \{2\}\}.
\]

Determine which of these sets are partitions of \( A \).

**Solution** The set \( S_1 \) is a partition of \( A \). The set \( S_2 \) is not a partition of \( A \) since \( \emptyset \) is one of the elements of \( S_2 \). The set \( S_3 \) is not a partition of \( A \) either since the element 5 belongs to
three distinct subsets in $S_3$, namely, $\{3, 4, 5\}$ and $\{5, 6\}$. Finally, $S_4$ is also not a partition of $A$ because the element 6 belongs to no subset in $S_4$.

As the word “partition” probably suggests, a partition of a nonempty set $A$ is a division of $A$ into nonempty subsets. The partition $S_1$ of the set $A$ in Example 1.22 is illustrated in the diagram shown in Figure 1.7.

![Figure 1.7 A partition of a set](image)

For example, the set $\mathbb{Z}$ of integers can be partitioned into the set of even integers and the set of odd integers. The set $\mathbb{R}$ of real numbers can be partitioned into the set $\mathbb{R}^+$ of positive real numbers, the set of negative real numbers and the set $\{0\}$ consisting of the number 0. In addition, $\mathbb{R}$ can be partitioned into the set $\mathbb{Q}$ of rational numbers and the set $\mathbb{I}$ of irrational numbers.

**Example 1.23** Let $A = \{1, 2, \ldots, 12\}$.

(a) Give an example of a partition $S$ of $A$ such that $|S| = 5$.

(b) Give an example of a subset $T$ of the partition $S$ in (a) such that $|T| = 3$.

(c) List all those elements $B$ in the partition $S$ in (a) such that $|B| = 2$.

**Solution**

(a) We are seeking a partition $S$ of $A$ consisting of five subsets. One such example is

$$S = \{\{1, 2\}, \{3, 4\}, \{5, 6\}, \{7, 8, 9\}, \{10, 11, 12\}\}.$$  

(b) We are seeking a subset $T$ of $S$ (given in (a)) consisting of three elements. One such example is

$$T = \{\{1, 2\}, \{3, 4\}, \{7, 8, 9\}\}.$$  

(c) We have been asked to list all those elements of $S$ (given in (a)) consisting of two elements of $A$. These elements are $\{1, 2\}, \{3, 4\}, \{5, 6\}$.

**SECTION 1.5 EXERCISES**

1.48. Which of the following are partitions of $A = \{a, b, c, d, e, f, g\}$? For each collection of subsets that is not a partition of $A$, explain your answer.

(a) $S_1 = \{\{a, c, e, g\}, \{b, f\}, \{d\}\}$  
(b) $S_2 = \{\{a, b, c, d\}, \{e, f\}\}$

(c) $S_3 = \{\{a\}\}$  
(d) $S_4 = \{\{a\}, \emptyset, \{b, c, d\}, \{e, f, g\}\}$

(e) $S_5 = \{\{a, c, d\}, \{b, g\}, \{e\}, \{b, f\}\}$.
1.49. Which of the following sets are partitions of \( A = \{1, 2, 3, 4, 5\} \)?

(a) \( S_1 = \{\{1, 3\}, \{2, 5\}\} \)  
(b) \( S_2 = \{\{1, 2\}, \{3, 4, 5\}\} \)  
(c) \( S_3 = \{\{1, 2\}, \{2, 3\}, \{3, 4\}, \{4, 5\}\} \)  
(d) \( S_4 = A \).

1.50. Let \( A = \{1, 2, 3, 4, 5, 6\} \). Give an example of a partition \( S \) of \( A \) such that \( |S| = 3 \).

1.51. Give an example of a set \( A \) with \( |A| = 4 \) and two disjoint partitions \( S_1 \) and \( S_2 \) of \( A \) with \( |S_1| = |S_2| = 3 \).

1.52. Give an example of a partition of \( \mathbb{N} \) into three subsets.

1.53. Give an example of a partition of \( \mathbb{Q} \) into three subsets.

1.54. Give an example of three sets \( A, S_1 \) and \( S_2 \) such that \( S_1 \) is a partition of \( A \), \( S_2 \) is a partition of \( S_1 \) and \( |S_2| < |S_1| < |A| \).

1.55. Give an example of a partition of \( \mathbb{Z} \) into four subsets.

1.56. Let \( A = \{1, 2, \ldots, 12\} \). Give an example of a partition \( S \) of \( A \) satisfying the following requirements: (i) \( |S| = 5 \), (ii) there is a subset \( T \) of \( S \) such that \( |T| = 4 \) and \( \cup_{x \in T} x \) has 10, and (iii) there is no element \( B \in S \) such that \( |B| = 3 \).

1.57. A set \( S \) is partitioned into two subsets \( S_1 \) and \( S_2 \). This produces a partition \( P_1 \) of \( S \) where \( P_1 = \{S_1, S_2\} \) and so \( |P_1| = 2 \). One of the sets in \( P_1 \) is then partitioned into two subsets, producing a partition \( P_2 \) of \( S \) with \( |P_2| = 3 \). A total of \( |P_1| \) sets in \( P_2 \) are partitioned into two subsets each, producing a partition \( P_3 \) of \( S \). This is continued until a partition \( P_6 \) of \( S \) is produced. What is \( |P_6| \)?

1.58. It was mentioned that there are three ways that a collection \( S \) of subsets of a nonempty set \( A \) is defined to be a partition of \( A \).

**Definition 1** The collection \( S \) consists of pairwise disjoint nonempty subsets of \( A \) and every element of \( A \) belongs to a subset in \( S \).

**Definition 2** The collection \( S \) consists of nonempty subsets of \( A \) and every element of \( A \) belongs to exactly one subset in \( S \).

**Definition 3** The collection \( S \) consists of subsets of \( A \) satisfying the three properties (1) every subset in \( S \) is nonempty, (2) every two subsets of \( A \) are equal or disjoint, and (3) the union of all subsets in \( S \) is \( A \).

(a) Show that any collection \( S \) of subsets of \( A \) satisfying Definition 1 satisfies Definition 2.

(b) Show that any collection \( S \) of subsets of \( A \) satisfying Definition 2 satisfies Definition 3.

(c) Show that any collection \( S \) of subsets of \( A \) satisfying Definition 3 satisfies Definition 1.

### 1.6 Cartesian Products of Sets

We’ve already mentioned that when a set \( A \) is described by listing its elements, the order in which the elements of \( A \) are listed doesn’t matter. That is, if the set \( A \) consists of two elements \( x \) and \( y \), then \( A = \{x, y\} = \{y, x\} \). When we speak of the **ordered pair** \( (x, y) \), however, this is another story. The ordered pair \( (x, y) \) is a single element consisting of a pair of elements in which \( x \) is the first element (or first coordinate) of the ordered pair \( (x, y) \) and \( y \) is the second element (or second coordinate). Moreover, for two ordered pairs \( (x, y) \) and \( (w, z) \) to be equal, that is, \( (x, y) = (w, z) \), we must have \( x = w \) and \( y = z \). So, if \( x \neq y \), then \( (x, y) \neq (y, x) \).

The **Cartesian product** (or simply the product) \( A \times B \) of two sets \( A \) and \( B \) is the set consisting of all ordered pairs whose first coordinate belongs to \( A \) and whose second
Chapter 1

Sets

coordinate belongs to $B$. In other words,

$$A \times B = \{(a, b) : a \in A \text{ and } b \in B\}.$$ 

**Example 1.24** If $A = \{x, y\}$ and $B = \{1, 2, 3\}$, then

$$A \times B = \{(x, 1), (x, 2), (x, 3), (y, 1), (y, 2), (y, 3)\},$$

while

$$B \times A = \{(1, x), (1, y), (2, x), (2, y), (3, x), (3, y)\}.$$

Since, for example, $(x, 1) \in A \times B$ and $(x, 1) \notin B \times A$, these two sets do not contain the same elements; so $A \times B \neq B \times A$. Also,

$$A \times A = \{(x, x), (x, y), (y, x), (y, y)\}$$

and

$$B \times B = \{(1, 1), (1, 2), (1, 3), (2, 1), (2, 2), (2, 3), (3, 1), (3, 2), (3, 3)\}.$$ 

We also note that if $A = \emptyset$ or $B = \emptyset$, then $A \times B = \emptyset$.

The Cartesian product $\mathbb{R} \times \mathbb{R}$ is the set of all points in the Euclidean plane. For example, the graph of the straight line $y = 2x + 3$ is the set

$$\{(x, y) \in \mathbb{R} \times \mathbb{R} : y = 2x + 3\}.$$ 

For the sets $A = \{x, y\}$ and $B = \{1, 2, 3\}$ given in Example 1.24, $|A| = 2$ and $|B| = 3$; while $|A \times B| = 6$. Indeed, for all finite sets $A$ and $B$,

$$|A \times B| = |A| \cdot |B|.$$

Cartesian products will be explored in more detail in Chapters 4 and 9.

**SECTION 1.6 EXERCISES**

1.59. Let $A = \{x, y, z\}$ and $B = \{x, y\}$. Determine $A \times B$.

1.60. Let $A = \{1, \{1\}\}, \{\{1\}\}$. Determine $A \times A$.

1.61. For $A = \{a, b\}$, determine $A \times \mathcal{P}(A)$.

1.62. For $A = \emptyset, \{\emptyset\}$, determine $A \times \mathcal{P}(A)$.

1.63. For $A = \{1, 2\}$ and $B = \emptyset$, determine $A \times B$ and $\mathcal{P}(A) \times \mathcal{P}(B)$.

1.64. Describe the graph of the circle whose equation is $x^2 + y^2 = 4$ as a subset of $\mathbb{R} \times \mathbb{R}$.

1.65. List the elements of the set $S = \{(x, y) \in \mathbb{Z} \times \mathbb{Z} : |x| + |y| = 3\}$. Plot the corresponding points in the Euclidean $x$-$y$ plane.

1.66. For $A = \{1, 2\}$ and $B = \{1\}$, determine $\mathcal{P}(A \times B)$.

1.67. For $A = \{x \in \mathbb{R} : |x - 1| \leq 2\}$ and $B = \{y \in \mathbb{R} : |y - 4| \leq 2\}$, give a geometric description of the points in the $xy$-plane belonging to $A \times B$.

1.68. For $A = \{a \in \mathbb{R} : |a| \leq 1\}$ and $B = \{b \in \mathbb{R} : |b| = 1\}$, give a geometric description of the points in the $xy$-plane belonging to $(A \times B) \cup (B \times A)$. 

1.69. Let $A = \{1, 2, 3\}$ and $B = \{2, 3, 4\}$. Determine the following:

(a) $(A \times B) \cap (B \times A)$
(b) $(A \cap B) \times (B \cap A)$

1.70. Let $R = \{(1, 1), (2, 1), (3, 2), (3, 3), (4, 2), (4, 3)\}$ be a collection of ordered pairs. Find subsets $A, B, C, D$ of the set $\{1, 2, 3, 4\}$ such that $R = ((A \times B) \cup (C \times D)) - (D \times D)$.

1.71. For $i = 1, 2, 3$, let $A_i = \{i, i + 1\}$. Determine $\bigcup_{i=1}^{3} (A_i \times A_i)$.

1.72. For $A = \{1, 2\}$ and $B = \{3, 4\}$, it follows that $P = \{A, B\}$ is a partition of the set $S = \{1, 2, 3, 4\}$. Describe a partition of $S \times S$ in terms of Cartesian products of the sets $A$ and $B$.

---

**Chapter 1 Supplemental Exercises**

1.73. The set $T = \{2k + 1 : k \in \mathbb{Z}\}$ can be described as $T = \{\ldots, -3, -1, 1, 3, \ldots\}$. Describe each of the following sets in a similar manner.

(a) $A = \{4k + 3 : k \in \mathbb{Z}\}$
(b) $B = \{5k - 1 : k \in \mathbb{Z}\}$.

1.74. Let $S = \{-10, -9, \ldots, 9, 10\}$. Describe each of the following sets as $\{x \in S : p(x)\}$, where $p(x)$ is some condition on $x$.

(a) $A = \{-10, -9, \ldots, -1, 1, 1, \ldots, 9, 10\}$
(b) $B = \{-10, -9, \ldots, -1, 0\}$
(c) $C = \{-5, -4, \ldots, 0, 1, 1, \ldots, 7\}$
(d) $D = \{-10, -9, \ldots, 4, 6, 7, \ldots, 10\}$.

1.75. Describe each of the following sets by listing its elements within braces.

(a) $\{x \in \mathbb{Z} : x^3 - 4x = 0\}$
(b) $\{x \in \mathbb{R} : |x| = 1\}$
(c) $\{m \in \mathbb{N} : 2 < m \leq 5\}$
(d) $\{n \in \mathbb{N} : 0 \leq n \leq 3\}$
(e) $\{k \in \mathbb{Q} : k^2 - 4 = 0\}$
(f) $\{k \in \mathbb{Z} : 9k^2 - 3 = 0\}$
(g) $\{k \in \mathbb{Z} : 1 \leq k^2 \leq 10\}$.

1.76. Determine the cardinality of each of the following sets.

(a) $A = \{1, 2, 3, \{1, 2, 3\}, 4, \{4\}\}$
(b) $B = \{x \in \mathbb{R} : |x| = 1\}$
(c) $C = \{m \in \mathbb{N} : 2 < m \leq 5\}$
(d) $D = \{n \in \mathbb{N} : n < 0\}$
(e) $E = \{k \in \mathbb{N} : 1 \leq k^2 \leq 100\}$
(f) $F = \{k \in \mathbb{Z} : 1 \leq k^2 \leq 100\}$.

1.77. For $A = \{-1, 0, 1\}$ and $B = \{x, y\}$, determine $A \times B$.

1.78. Let $U = \{1, 2, 3\}$ be the universal set and let $A = \{1, 2\}, B = \{2, 3\}$ and $C = \{1, 3\}$. Determine the following.

(a) $(A \cup B) - (B \cap C)$
(b) $\overline{A}$
(c) $\overline{B} \cup \overline{C}$
(d) $A \times B$.

1.79. Let $A = \{1, 2, \ldots, 10\}$. Give an example of two sets $S$ and $B$ such that $S \subseteq \mathcal{P}(A)$, $|S| = 4, B \in S$ and $|B| = 2$.

1.80. For $A = \{1\}$ and $C = \{1, 2\}$, give an example of a set $B$ such that $\mathcal{P}(A) \subseteq B \subseteq \mathcal{P}(C)$.

1.81. Give examples of two sets $A$ and $B$ such that $A \cap \mathcal{P}(A) \in B$ and $\mathcal{P}(A) \subseteq A \cup B$.

1.82. Which of the following sets are equal?

$$
A = \{n \in \mathbb{Z} : -4 \leq n \leq 4\} \quad D = \{x \in \mathbb{Z} : x^3 = 4x\}
B = \{x \in \mathbb{N} : 2x + 2 = 0\} \quad E = \{-2, 0, 2\}
C = \{x \in \mathbb{Z} : 3x - 2 = 0\}
$$
1.83. Let \( A \) and \( B \) be subsets of some unknown universal set \( U \). Suppose that \( \overline{A} = \{3, 8, 9\} \), \( A - B = \{1, 2\} \), \( B - A = \{8\} \) and \( A \cap B = \{5, 7\} \). Determine \( U \), \( A \) and \( B \).

1.84. Let \( I \) denote the interval \([0, \infty)\). For each \( r \in I \), define

\[
A_r = \{(x, y) \in \mathbb{R} \times \mathbb{R} : x^2 + y^2 = r^2\} \\
B_r = \{(x, y) \in \mathbb{R} \times \mathbb{R} : x^2 + y^2 \leq r^2\} \\
C_r = \{(x, y) \in \mathbb{R} \times \mathbb{R} : x^2 + y^2 > r^2\}.
\]

(a) Determine \( \bigcup_{r \in I} A_r \) and \( \bigcap_{r \in I} A_r \).
(b) Determine \( \bigcup_{r \in I} B_r \) and \( \bigcap_{r \in I} B_r \).
(c) Determine \( \bigcup_{r \in I} C_r \) and \( \bigcap_{r \in I} C_r \).

1.85. Give an example of four sets \( A_1, A_2, A_3, A_4 \) such that \( |A_i \cap A_j| = |i - j| \) for every two integers \( i \) and \( j \) with \( 1 \leq i < j \leq 4 \).

1.86. (a) Give an example of two problems suggested by Exercise 1.85 (above).
(b) Solve one of the problems in (a).

1.87. Let \( A = \{1, 2, 3\} \), \( B = \{1, 2, 3, 4\} \) and \( C = \{1, 2, 3, 4, 5\} \). For the sets \( S \) and \( T \) described below, explain whether \( |S| < |T| \), \( |S| > |T| \) or \( |S| = |T| \).

(a) Let \( B \) be the universal set and let \( S \) be the set of all subsets \( X \) of \( B \) for which \( |X| \neq |X^c| \). Let \( T \) be the set of 2-element subsets of \( C \).
(b) Let \( S \) be the set of all partitions of the set \( A \) and let \( T \) be the set of 4-element subsets of \( C \).
(c) Let \( S = \{(a, b) : b \in B, a \in A, a + b \text{ is odd}\} \) and let \( T \) be the set of all nonempty proper subsets of \( A \).

1.88. Give an example of a set \( A = \{1, 2, \ldots, k\} \) for a smallest \( k \in \mathbb{N} \) containing subsets \( A_1, A_2, A_3 \) such that \( |A_i - A_j| = |A_j - A_i| = |i - j| \) for every two integers \( i \) and \( j \) with \( 1 \leq i < j \leq 3 \).

1.89. (a) For \( A = \{-3, -2, \ldots, 4\} \) and \( B = \{1, 2, \ldots, 6\} \), determine \( S = \{(a, b) \in A \times B : a^2 + b^2 = 25\} \).
(b) For \( C = \{a \in B : (a, b) \in S\} \) and \( D = \{b \in A : (a, b) \in S\} \), where \( A, B, S \) are the sets in (a), determine \( C \times D \).

1.90. For \( A = \{1, 2, 3\} \), let \( B \) be the set of 2-element sets belonging to \( \mathcal{P}(A) \) and let \( C \) be the set consisting of the sets that are the intersections of two distinct elements of \( B \). Determine \( D = \mathcal{P}(C) \).

1.91. For a real number \( r \), let \( A_r = \{r, r + 1\} \). Let \( S = \{x \in \mathbb{R} : x^2 + 2x - 1 = 0\} \).

(a) Determine \( B = A_t \times A_s \) for the distinct elements \( s, t \in S \), where \( s < t \).
(b) Let \( C = \{ab : (a, b) \in B\} \). Determine the sum of the elements of \( C \).

1.92. (a) For a set \( A \) with \( |A| = 2 \), what is the largest possible value of \( |A \cap \mathcal{P}(A)| \)?
(b) What is the largest possible value of \( |A \cap \mathcal{P}(A)| \) if \( |A| = 3 \)?
(c) This should suggest another question to you. What is the answer to your question?

1.93. For \( n \in \mathbb{N} \), let \( S_n = \left\{ x + y : x, y \in \mathbb{R}, \frac{1}{n^2} \leq x^2 + y^2 \leq 1 \right\} \). Determine \( \bigcup_{n=1}^{\infty} S_n \) and \( \bigcap_{n=1}^{\infty} S_n \).
1.94. For the set \( S = \{1, 2, \ldots, 7\} \), consider the five subsets
\( A_1 = \{1, 2\}, A_2 = \{3, 4, 5\}, A_3 = \{2, 5, 6\}, A_4 = \{2, 7\}, A_5 = \{1, 2\} \).

(a) Is the collection \( P_1 = \{A_1, A_2, A_3, A_4, A_5\} \) a partition of \( S \)?

(b) Let \( B_i = A_i - A_{i+1} \) for \( i = 1, 2, 3, 4 \). Is \( P_2 = \{B_1, B_2, B_3, B_4\} \) a partition of \( S \)?

(c) Let \( C_i = A_{6-i} - A_{5-i} \) for \( i = 1, 2, 3, 4 \). Is \( P_3 = \{C_1, C_2, C_3, C_4\} \) a partition of \( S \)?

1.95. Let \( S = \{1, 2, 3\} \). Find a condition under which nonempty subsets \( A, B, C \) of \( S \) have the property that \(|A \times (B \cup C)| = |A \times B| + |A \times C|\).
In mathematics our goal is to seek the truth. Are there connections between two given mathematical concepts? If so, what are they? Under what conditions does an object possess a particular property? Finding answers to questions such as these is important, but we cannot be satisfied only with this. We must be certain that we are right and that our explanation for why we believe we are correct is convincing to others. The reasoning we use as we proceed from what we know to what we wish to show must be logical. It must make sense to others, not just to ourselves.

There is joint responsibility here, however. It is the writer’s responsibility to use the rules of logic to give a valid and clear argument with enough details provided to allow the reader to understand what we have written and to be convinced. It is the reader’s responsibility to know the basics of logic and to study the concepts involved sufficiently well so that he or she will not only be able to understand a well-presented argument but can decide as well whether it is valid. Consequently, both writer and reader must be familiar with logic.

Although it is possible to spend a great deal of time studying logic, we will present only what we actually need and will instead use the majority of our time putting what we learn into practice.

2.1 STATEMENTS

In mathematics we are constantly dealing with statements. By a **statement** we mean a declarative sentence or assertion that is true or false (but not both). Statements therefore declare or assert the truth of something. Of course, the statements in which we will be primarily interested deal with mathematics. For example, the sentences

- The integer 3 is odd.
- The integer 57 is prime.

are statements (only the first of which is true).

Every statement has a **truth value**, namely **true** (denoted by $T$) or **false** (denoted by $F$). We often use $P$, $Q$ and $R$ to denote statements, or perhaps $P_1, P_2, \ldots, P_n$ if there are several statements involved. We have seen that

- $P_1$ : The integer 3 is odd.
2.1 Statements

and

\[ P_2 : \text{The integer 57 is prime.} \]

are statements, where \( P_1 \) has truth value \( T \) and \( P_2 \) has truth value \( F \).

Sentences that are imperative (commands) such as

- Substitute the number 2 for \( x \).
- Find the derivative of \( f(x) = e^{-x} \cos 2x \).

or are interrogative (questions) such as

- Are these sets disjoint?
- What is the derivative of \( f(x) = e^{-x} \cos 2x \)?

or are exclamatory such as

- What an interesting question!
- How difficult this problem is!

are not statements since these sentences are not declarative.

It may not be immediately clear whether a statement is true or false. For example, the sentence “The 100th digit in the decimal expansion of \( \pi \) is 7.” is a statement, but it may be necessary to find this information in a website on the Internet to determine whether this statement is true. Indeed, for a sentence to be a statement, it is not a requirement that we know or are able to determine its truth value.

The sentence “The real number \( r \) is rational.” is a statement provided we know what real number \( r \) is being referred to. Without this additional information, however, it is impossible to assign a truth value to it. This is an example of what is often referred to as an open sentence. In general, an open sentence is a declarative sentence that contains one or more variables, each variable representing a value in some prescribed set, called the domain of the variable, and which becomes a statement when values from their respective domains are substituted for these variables. For example, the open sentence “\( 3x = 12 \)” where the domain of \( x \) is the set of integers is a true statement only when \( x = 4 \).

An open sentence that contains a variable \( x \) is typically represented by \( P(x) \), \( Q(x) \) or \( R(x) \). If \( P(x) \) is an open sentence, where the domain of \( x \) is \( S \), then we say \( P(x) \) is an open sentence over the domain \( S \). Also, \( P(x) \) is a statement for each \( x \in S \). For example, the open sentence

\[ P(x) : (x - 3)^2 \leq 1 \]

over the domain \( \mathbb{Z} \) is a true statement when \( x \in \{2, 3, 4\} \) and is a false statement otherwise.

**Example 2.1** For the open sentence

\[ P(x, y) : |x + 1| + |y| = 1 \]

in two variables, suppose that the domain of the variable \( x \) is \( S = \{-2, -1, 0\} \) and the domain of the variable \( y \) is \( T = \{-1, 0, 1\} \). Then

\[ P(-1, 1) : |(-1) + 1| + |1| = 1 \]
is a true statement, while

\[ P(1, -1) : |1 + 1| + | - 1| = 1 \]

is a false statement. In fact, \( P(x, y) \) is a true statement when

\( (x, y) \in \{(-2, 0), (-1, -1), (-1, 1), (0, 0)\}, \)

while \( P(x, y) \) is a false statement for all other elements \( (x, y) \in S \times T \).

The possible truth values of a statement are often listed in a table, called a truth table. The truth tables for two statements \( P \) and \( Q \) are given in Figure 2.1. Since there are two possible truth values for each of \( P \) and \( Q \), there are four possible combinations of truth values for \( P \) and \( Q \). The truth table showing all these combinations is also given in Figure 2.1. If a third statement \( R \) is involved, then there are eight possible combinations of truth values for \( P, Q \) and \( R \). This is displayed in Figure 2.1 as well. In general, a truth table involving \( n \) statements \( P_1, P_2, \ldots, P_n \) contains \( 2^n \) possible combinations of truth values for these statements and a truth table showing these combinations would have \( n \) columns and \( 2^n \) rows. Much of the time, we will be dealing with two statements, usually denoted by \( P \) and \( Q \); so the associated truth table will have four rows with the first two columns headed by \( P \) and \( Q \). In this case, it is customary to consider the four combinations of the truth values in the order TT, TF, FT, FF from top to bottom.

\[
\begin{array}{c|c|c|c|c|c}
P & Q & P & Q & P & Q \\
T & T & T & T & T & T \\
F & F & F & F & F & F \\
\end{array}
\]

\[
\begin{array}{c|c|c|c|c|c|c|c|c}
 & & & & & & & & \\
T & T & T & T & T & T & T & T & T \\
T & T & F & T & F & F & F & F & F \\
F & T & T & T & F & F & F & F & F \\
F & F & T & F & T & T & T & T & T \\
\end{array}
\]

Figure 2.1 Truth tables for one, two and three statements

SECTION 2.1 EXERCISES

2.1. Which of the following sentences are statements? For those that are, indicate the truth value.

(a) The integer 123 is prime.  
(b) The integer 0 is even.  
(c) Is \( 5 \times 2 = 10? \)  
(d) \( x^2 - 4 = 0. \)

(e) Multiply \( 5x + 2 \) by 3.  
(f) \( 5x + 3 \) is an odd integer.  
(g) What an impossible question!
2.2. Consider the sets $A$, $B$, $C$, and $D$ below. Which of the following statements are true? Give an explanation for each false statement.

$$A = \{1, 4, 7, 10, 13, 16, \ldots \} \quad C = \{x \in \mathbb{Z} : x \text{ is prime and } x \neq 2\}$$

$$B = \{x \in \mathbb{Z} : x \text{ is odd} \} \quad D = \{1, 2, 3, 5, 8, 13, 21, 34, 55, \ldots \}$$

(a) $25 \in A$  (b) $33 \in D$  (c) $22 \notin A \cup D$  (d) $C \subseteq B$  (e) $\emptyset \in B \cap D$  (f) $53 \notin C$.

2.3. Which of the following statements are true? Give an explanation for each false statement.

(a) $\emptyset \notin \emptyset$  (b) $\emptyset \notin \emptyset$  (c) $\{1, 3\} = \{3, 1\}$

(d) $\emptyset = \emptyset$  (e) $\emptyset \subset \emptyset$  (f) $1 \subseteq \{1\}$.

2.4. Consider the open sentence $P(x) : x(x - 1) = 6$ over the domain $\mathbb{R}$.

(a) For what values of $x$ is $P(x)$ a true statement?

(b) For what values of $x$ is $P(x)$ a false statement?

2.5. For the open sentence $P(x) : 3x - 2 > 4$ over the domain $\mathbb{Z}$, determine:

(a) the values of $x$ for which $P(x)$ is true.

(b) the values of $x$ for which $P(x)$ is false.

2.6. For the open sentence $Q(A) : A \subseteq \{1, 2, 3\}$ over the domain $S = \mathcal{P}([1, 2, 4])$, determine:

(a) all $A \in S$ for which $Q(A)$ is true.

(b) all $A \in S$ for which $Q(A)$ is false.

(c) all $A \in S$ for which $A \cap \{1, 2, 3\} = \emptyset$.

2.7. Let $P(n)$: $n$ and $n + 2$ are primes. be an open sentence over the domain $\mathbb{N}$. Find six positive integers $n$ for which $P(n)$ is true. If $n \in \mathbb{N}$ such that $P(n)$ is true, then the two integers $n$, $n + 2$ are called twin primes. It has been conjectured that there are infinitely many twin primes.

2.8. Let $P(n) : \frac{n^2 + 5n + 6}{2}$ is even.

(a) Find a set $S_1$ of three integers such that $P(n)$ is an open sentence over the domain $S_1$ and $P(n)$ is true for each $n \in S_1$.

(b) Find a set $S_2$ of three integers such that $P(n)$ is an open sentence over the domain $S_2$ and $P(n)$ is false for each $n \in S_2$.

2.9. Find an open sentence $P(n)$ over the domain $S = \{3, 5, 7, 9\}$ such that $P(n)$ is true for half of the integers in $S$ and false for the other half.

2.10. Find two open sentences $P(n)$ and $Q(n)$, both over the domain $S = \{2, 4, 6, 8\}$, such that $P(2)$ and $Q(2)$ are both true, $P(4)$ and $Q(4)$ are both false, $P(6)$ is true and $Q(6)$ is false, while $P(8)$ is false and $Q(8)$ is true.

2.2 NEGATIONS

Much of the interest in integers and other familiar sets of numbers comes not only from the numbers themselves but from properties of the numbers that result by performing operations on them (such as taking their negatives, adding or multiplying them, or combinations of these). Similarly, much of our interest in statements comes from investigating the truth or falseness of new statements that can be produced from one or more given statements by performing certain operations on them. Our first example concerns producing a new statement from a single given statement.

The negation of a statement $P$ is the statement

$$\text{not } P$$
and is denoted by $\sim P$. (The negation of a statement $P$ is expressed as $\neg P$ by some, but we will denote the negation of $P$ by $\sim P$.)

Although $\sim P$ could always be expressed as “It is not the case that $P$,” there are better ways to express the statement $\sim P$ in words. Consequently, we follow the practice of not expressing negation in this manner.

**Example 2.2** For the statement

$$P_1: \text{The integer 3 is odd.}$$

described above, we have

$$\sim P_1: \text{The integer 3 is not odd.}$$

or better yet to write

$$\sim P_1: \text{The integer 3 is even.}$$

Similarly, the negation of the statement

$$P_2: \text{The integer 57 is prime.}$$

considered above is

$$\sim P_2: \text{The integer 57 is not prime.}$$

Note that $\sim P_1$ is false, while $\sim P_2$ is true.

Indeed, the negation of a true statement is always false and the negation of a false statement is always true; that is, the truth value of $\sim P$ is opposite to that of $P$. This is summarized in Figure 2.2, which gives the truth table for $\sim P$ (in terms of the possible truth values of $P$).

<table>

</tbody>
</table>

Figure 2.3  The truth table for Exercise 2.12.

2.13. State the negation of each of the following statements.
   
   (a) The real number $r$ is at most $\sqrt{2}$.
   
   (b) The absolute value of the real number $a$ is less than 3.
   
   (c) Two angles of the triangle are $45^\circ$.
   
   (d) The area of the circle is at least $9\pi$.
   
   (e) Two sides of the triangle have the same length.
   
   (f) The point $P$ in the plane lies outside of the circle $C$.

2.14. State the negation of each of the following statements.
   
   (a) At least two of my library books are overdue.
   
   (b) One of my two friends misplaced his homework assignment.
   
   (c) No one expected that to happen.
   
   (d) It’s not often that my instructor teaches that course.
   
   (e) It’s surprising that two students received the same exam score.

2.3 DISJUNCTIONS AND CONJUNCTIONS

For two given statements $P$ and $Q$, a common way to produce a new statement from them is by inserting the word “or” or “and” between $P$ and $Q$. The **disjunction** of the statements $P$ and $Q$ is the statement

\[ P \lor Q \]

and is denoted by $P \lor Q$. The disjunction $P \lor Q$ is true if at least one of $P$ and $Q$ is true; otherwise, $P \lor Q$ is false. Therefore, $P \lor Q$ is true if exactly one of $P$ and $Q$ is true or if both $P$ and $Q$ are true.

**Example 2.3**  For the statements

\[ P_1 : \text{The integer } 3 \text{ is odd. and } P_2 : \text{The integer } 57 \text{ is prime.} \]

described earlier, the disjunction is the new statement

\[ P_1 \lor P_2 : \text{Either } 3 \text{ is odd or } 57 \text{ is prime.} \]
Chapter 2 Logic

which is true since at least one of \( P_1 \) and \( P_2 \) is true (namely, \( P_1 \) is true). Of course, in this case exactly one of \( P_1 \) and \( P_2 \) is true.

For two statements \( P \) and \( Q \), the truth table for \( P \lor Q \) is shown in Figure 2.4. This truth table then describes precisely when \( P \lor Q \) is true (and when it is false).

<table>
<thead>
<tr>
<th>( P )</th>
<th>( Q )</th>
<th>( P \lor Q )</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>T</td>

<td>T</td>
</tr>
<tr>
<td>F</td>
<td>T</td>
<td>T</td>
</tr>
<tr>
<td>F</td>
<td>F</td>
<td>F</td>
</tr>
</tbody>
</table>

Figure 2.4 The truth table for disjunction

The **conjunction** of the statements \( P \) and \( Q \) is the statement

\[
P \land Q
\]

and is denoted by \( P \land Q \). The conjunction \( P \land Q \) is true only when both \( P \) and \( Q \) are true; otherwise, \( P \land Q \) is false.

**Example 2.4** For \( P_1 \) : The integer 3 is odd. and \( P_2 \) : The integer 57 is prime., the statement

\[
P_1 \land P_2 : 3 \text{ odd and 57 is prime.}
\]

is false since \( P_2 \) is false and so not both \( P_1 \) and \( P_2 \) are true.

The truth table for the conjunction of two statements is shown in Figure 2.5.

<table>
<thead>
<tr>
<th>( P )</th>
<th>( Q )</th>
<th>( P \land Q )</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>T</td>
<td>T</td>

<td>F</td>
<td>F</td>
</tr>
</tbody>
</table>

Figure 2.5 The truth table for conjunction

Since the statement \( P_3 : 59 \text{ is prime.} \) is true, it follows that the conjunction

\[
P_1 \land P_3 : 3 \text{ odd and 59 is prime.}
\]

is a true statement.
SECTION 2.3 EXERCISES

2.15. Complete the truth table in Figure 2.6.

\[
\begin{array}{cccc}
P & Q & \sim Q & P \land (\sim Q) \\
T & T & & \\
T & F & & \\
F & T & & \\
F & F & & \\
\end{array}
\]

Figure 2.6  The truth table for Exercise 2.15.

2.16. For the sets \(A = \{1, 2, \cdots, 10\}\) and \(B = \{2, 4, 6, 9, 12, 25\}\), consider the statements

\[
P: A \subseteq B. \quad Q: |A - B| = 6.
\]

Determine which of the following statements are true.

(a) \(P \lor Q\)  \(\text{ (b) } P \lor (\sim Q) \quad \text{(c) } P \land Q\)

(d) \((\sim P) \land Q\)  \(\text{ (e) } (\sim P) \lor (\sim Q)\).

2.17. Let \(P: 15\) is odd. and \(Q: 21\) is prime. State each of the following in words and determine whether it is true or false.

(a) \(P \lor Q\)  \(\text{ (b) } P \land Q \quad \text{(c) } (\sim P) \lor Q \quad \text{(d) } P \land (\sim Q)\).

2.18. Let \(S = \{1, 2, \ldots, 6\}\) and let

\[
P(A): A \cap \{2, 4, 6\} = \emptyset. \quad \text{and } Q(A): A \neq \emptyset.
\]

be open sentences over the domain \(\mathcal{P}(S)\).

(a) Determine all \(A \in \mathcal{P}(S)\) for which \(P(A) \land Q(A)\) is true.

(b) Determine all \(A \in \mathcal{P}(S)\) for which \(P(A) \lor (\sim Q(A))\) is true.

(c) Determine all \(A \in \mathcal{P}(S)\) for which \((\sim P(A)) \land (\sim Q(A))\) is true.

2.4 IMPLICATIONS

A statement formed from two given statements in which we will be most interested is the implication (also called the conditional). For statements \(P\) and \(Q\), the implication (or conditional) is the statement

\[
\text{If } P, \text{ then } Q.
\]

and is denoted by \(P \Rightarrow Q\). In addition to the wording “If \(P\), then \(Q\)”, we also express \(P \Rightarrow Q\) in words as

\[
P \text{ implies } Q.
\]

The truth table for \(P \Rightarrow Q\) is given in Figure 2.7.

Notice that \(P \Rightarrow Q\) is false only when \(P\) is true and \(Q\) is false (\(P \Rightarrow Q\) is true otherwise).
Chapter 2 Logic

46

Example 2.5 For $P_1$: The integer 3 is odd. and $P_2$: The integer 57 is prime., the implication

$$P_1 \Rightarrow P_2 : \text{If 3 is an odd integer, then 57 is prime.}$$

is a false statement. The implication

$$P_2 \Rightarrow P_1 : \text{If 57 is prime, then 3 is odd.}$$

is true, however. ♦

While the truth tables for the negation $\sim P$, the disjunction $P \lor Q$ and the conjunction $P \land Q$ are probably what one would expect, this may not be so for the implication $P \Rightarrow Q$. There is ample justification, however, for the truth values in the truth table of $P \Rightarrow Q$. We illustrate this with an example.

Example 2.6 A student is taking a math class (let’s say this one) and is currently receiving a $B\!+$. He visits his instructor a few days before the final examination and asks her, “Is there any chance that I can get an $A$ in this course?” His instructor looks through her grade book and says, “If you earn an $A$ on the final exam, then you will receive an $A$ for your final grade.” We now check the truth or falseness of this implication based on the various combinations of truth values of the statements

$P$: You earn an $A$ on the final exam.

and

$Q$: You receive an $A$ for your final grade.

which make up the implication.

Analysis Suppose first that $P$ and $Q$ are both true. That is, the student receives an $A$ on his final exam and later learns that he got an $A$ for his final grade in the course. Did his instructor tell the truth? I think we would all agree that she did. So if $P$ and $Q$ are both true, then so too is $P \Rightarrow Q$, which agrees with the first row of the truth table of Figure 2.7.

Second, suppose that $P$ is true and $Q$ is false. So the student got an $A$ on his final exam but did not receive an $A$ as a final grade (say he received a $B$). Certainly, his instructor did not do as she promised (as she will soon be reminded by her student). What she said was false, which agrees with the second row of the table in Figure 2.7.
Third, suppose that $P$ is false and $Q$ is true. In this case, the student did not get an A on his final exam (say he earned a B), but when he received his final grades, he learned (and was pleasantly surprised) that his final grade was an A. How could this happen? Perhaps his instructor was lenient. Perhaps the final exam was unusually difficult and a grade of $B$ on it indicated an exceptionally good performance. Perhaps the instructor made a mistake. In any case, the instructor did not lie; so she told the truth. Indeed, she never promised anything if the student did not get an A on his final exam. This agrees with the third row of the table in Figure 2.7.

Finally, suppose that $P$ and $Q$ are both false. That is, suppose the student did not get an A on his final exam and he also did not get an A for a final grade. The instructor did not lie here either. She only promised the student an A if he got an A on the final exam. Once again, she did not promise anything if the student did not get an A on the final exam. So the instructor told the truth and this agrees with the fourth and final row of the table.

In summary then, the only situation for which $P \Rightarrow Q$ is false is when $P$ is true and $Q$ is false (so $\sim Q$ is true). That is, the truth tables for

$$\sim (P \Rightarrow Q) \text{ and } P \land (\sim Q)$$

are the same. We’ll revisit this observation again soon.

We have already mentioned that the implication $P \Rightarrow Q$ can be expressed as both “If $P$, then $Q$” and “$P$ implies $Q$.” In fact, there are several ways of expressing $P \Rightarrow Q$ in words, namely:

- If $P$, then $Q$.
- $Q$ if $P$.
- $P$ implies $Q$.
- $P$ only if $Q$.
- $P$ is sufficient for $Q$.
- $Q$ is necessary for $P$.

It is probably not surprising that the first three of these say the same thing but perhaps not at all obvious that the last three say the same thing as the first three. Consider the statement “$P$ only if $Q$.” This says that $P$ is true only under the condition that $Q$ is true; in other words, it cannot be the case that $P$ is true and $Q$ is false. Thus, it says that if $P$ is true, then necessarily $Q$ must be true. We can also see from this that the statement “$Q$ is necessary for $P$” has the same meaning as “$P$ only if $Q$.” The statement “$P$ is sufficient for $Q$” states that the truth of $P$ is sufficient for the truth of $Q$. In other words, the truth of $P$ implies the truth of $Q$; that is, “$P$ implies $Q$.”

**SECTION 2.4 EXERCISES**

2.19. Consider the statements $P$: 17 is even. and $Q$: 19 is prime. Write each of the following statements in words and indicate whether it is true or false.

(a) $\sim P$  
(b) $P \lor Q$  
(c) $P \land Q$  
(d) $P \Rightarrow Q$.

2.20. For statements $P$ and $Q$, construct a truth table for $(P \Rightarrow Q) \Rightarrow (\sim P)$.
Chapter 2  Logic

2.21. Consider the statements \( P : \sqrt{2} \) is rational, and \( Q : \frac{22}{7} \) is rational. Write each of the following statements in words and indicate whether it is true or false.

(a) \( P \Rightarrow Q \)  
(b) \( Q \Rightarrow P \)  
(c) \( \sim P \Rightarrow \sim Q \)  
(d) \( \sim Q \Rightarrow \sim P \).

2.22. Consider the statements:

\( P : \sqrt{2} \) is rational.  \( Q : \frac{2}{7} \) is rational.  \( R : \sqrt{3} \) is rational.

Write each of the following statements in words and indicate whether the statement is true or false.

(a) \( (P \land Q) \Rightarrow R \)  
(b) \( (P \land Q) \Rightarrow (\sim R) \)  
(c) \( ((\sim P) \land Q) \Rightarrow R \)  
(d) \( (P \lor Q) \Rightarrow (\sim R) \).

2.23. Suppose that \( \{S_1, S_2\} \) is a partition of a set \( S \) and \( x \in S \). Which of the following are true?

(a) If we know that \( x \not\in S_1 \), then \( x \) must belong to \( S_2 \).
(b) It’s possible that \( x \not\in S_1 \) and \( x \not\in S_2 \).
(c) Either \( x \not\in S_1 \) or \( x \not\in S_2 \).
(d) Either \( x \in S_1 \) or \( x \in S_2 \).
(e) It’s possible that \( x \in S_1 \) and \( x \in S_2 \).

2.24. Two sets \( A \) and \( B \) are nonempty disjoint subsets of a set \( S \). If \( x \in S \), then which of the following are true?

(a) It’s possible that \( x \in A \cap B \).
(b) If \( x \) is an element of \( A \), then \( x \) can’t be an element of \( B \).
(c) If \( x \) is not an element of \( A \), then \( x \) must be an element of \( B \).
(d) It’s possible that \( x \not\in A \) and \( x \not\in B \).
(e) For each nonempty set \( C \), either \( x \in A \cap C \) or \( x \in B \cap C \).
(f) For some nonempty set \( C \), both \( x \in A \cup C \) and \( x \in B \cup C \).

2.25. A college student makes the following statement:

If I receive an A in both Calculus I and Discrete Mathematics this semester, then I’ll take either Calculus II or Computer Programming this summer.

For each of the following, determine whether the statement above is true or false.

(a) The student doesn’t get an A in Calculus I but decides to take Calculus II this summer anyway.
(b) The student gets an A in both Calculus I and Discrete Mathematics but decides not to take any class this summer.
(c) The student does not get an A in Calculus I and decides not to take Calculus II but takes Computer Programming this summer.
(d) The student gets an A in both Calculus I and Discrete Mathematics and decides to take both Calculus II and Computer Programming this summer.
(e) The student gets an A in neither Calculus I nor Discrete Mathematics and takes neither Calculus II nor Computer Programming this summer.

2.26. A college student makes the following statement:

If I don’t see my advisor today, then I’ll see her tomorrow.

For each of the following, determine whether the statement above is true or false.

(a) The student doesn’t see his advisor either day.
(b) The student sees his advisor both days.
(c) The student sees his advisor on one of the two days.
(d) The student doesn’t see his advisor today and waits until next week to see her.
2.27. The instructor of a computer science class announces to her class that there will be a well-known speaker on campus later that day. Four students in the class are Alice, Ben, Cindy and Don. Ben says that he’ll attend the lecture if Alice does. Cindy says that she’ll attend the talk if Ben does. Don says that he will go to the lecture if Cindy does. That afternoon exactly two of the four students attend the talk. Which two students went to the lecture?

2.28. Consider the statement (implication):
If Bill takes Sam to the concert, then Sam will take Bill to dinner. Which of the following implies that this statement is true?
(a) Sam takes Bill to dinner only if Bill takes Sam to the concert.
(b) Either Bill doesn’t take Sam to the concert or Sam takes Bill to dinner.
(c) Bill takes Sam to the concert.
(d) Bill takes Sam to the concert and Sam takes Bill to dinner.
(e) Bill takes Sam to the concert and Sam doesn’t take Bill to dinner.
(f) The concert is canceled.
(g) Sam doesn’t attend the concert.

2.29. Let $P$ and $Q$ be statements. Which of the following implies that $P \lor Q$ is false?
(a) $(\sim P) \lor (\sim Q)$ is false.
(b) $(\sim P) \lor Q$ is true.
(c) $(\sim P) \land (\sim Q)$ is true.
(d) $Q \Rightarrow P$ is true.
(e) $P \land Q$ is false.

2.5 MORE ON IMPLICATIONS

We have just discussed four ways to create new statements from one or two given statements. In mathematics, however, we are often interested in declarative sentences containing variables and whose truth or falseness is only known once we have assigned values to the variables. The values assigned to the variables come from their respective domains. These sentences are, of course, precisely the sentences we have referred to as open sentences. Just as new statements can be formed from statements $P$ and $Q$ by negation, disjunction, conjunction or implication, new open sentences can be constructed from open sentences in the same manner.

**Example 2.7** Consider the open sentences

$$P_1(x) : x = -3 \quad \text{and} \quad P_2(x) : |x| = 3.$$ 

where $x \in \mathbb{R}$, that is, where the domain of $x$ is $\mathbb{R}$ in each case. We can then form the following open sentences:

$$\sim P_1(x) : x \neq -3.$$ 

$$P_1(x) \lor P_2(x) : x = -3 \text{ or } |x| = 3.$$ 

$$P_1(x) \land P_2(x) : x = -3 \text{ and } |x| = 3.$$ 

$$P_1(x) \Rightarrow P_2(x) : \text{If } x = -3, \text{ then } |x| = 3.$$ 

For a specific real number $x$, the truth value of each resulting statement can be determined. For example, $\sim P_1(-3) : -3 \neq -3$ is a false statement; while each of the
remaining sentences above results in a true statement when \( x = -3 \). Both \( P_1(2) \lor P_2(2) \) and \( P_1(2) \land P_2(2) \) are false statements. On the other hand, both \( \sim P_1(2) \) and \( P_1(2) \Rightarrow P_2(2) \) are true statements. In fact, for each real number \( x \neq -3 \), the implication \( P_1(x) \Rightarrow P_2(x) \) is a true statement since \( P_1(x) : x = -3 \) is a false statement. Thus, \( P_1(x) \Rightarrow P_2(x) \) is true for all \( x \in \mathbb{R} \). We will see that open sentences that result in true statements for all values of the domain will be especially interesting to us.

Listed below are various ways of wording the implication \( P_1(T) \Rightarrow P_2(T) \):

- If \( x = -3 \), then \(|x| = 3\).
- \(|x| = 3\) if \( x = -3\).
- \( x = -3\) implies that \(|x| = 3\).
- \( x = -3\) only if \(|x| = 3\).
- \( x = -3\) is sufficient for \(|x| = 3\).
- \(|x| = 3\) is necessary for \( x = -3\).

We now consider another example, this time from geometry. You may recall that a triangle is called **equilateral** if the lengths of its three sides are the same, while a triangle is **isosceles** if the lengths of any two of its three sides are the same. Figure 2.8 shows an isosceles triangle \( T_1 \) and an equilateral triangle \( T_2 \). Actually, since the lengths of any two of the three sides of \( T_2 \) are the same, \( T_2 \) is isosceles as well. Indeed, this is precisely the fact we wish to discuss.

**Example 2.8** For a triangle \( T \), let

\[
P(T) : T \text{ is equilateral.} \quad \text{and} \quad Q(T) : T \text{ is isosceles.}
\]

Thus, \( P(T) \) and \( Q(T) \) are open sentences over the domain \( S \) of all triangles. Consider the implication \( P(T) \Rightarrow Q(T) \), where the domain then of the variable \( T \) is the set \( S \). For an equilateral triangle \( T_1 \), both \( P(T_1) \) and \( Q(T_1) \) are true statements and so \( P(T_1) \Rightarrow Q(T_1) \) is a true statement as well. If \( T_2 \) is not an equilateral triangle, then \( P(T_2) \) is a false statement and so \( P(T_2) \Rightarrow Q(T_2) \) is true regardless of the truth of \( P(T_2) \). Therefore, \( P(T) \Rightarrow Q(T) \) is a true statement for all \( T \in S \). We now state \( P(T) \Rightarrow Q(T) \) in a variety of ways:

- If \( T \) is an equilateral triangle, then \( T \) is isosceles.
- A triangle \( T \) is isosceles if \( T \) is equilateral.
- A triangle \( T \) being equilateral implies that \( T \) is isosceles.
- A triangle \( T \) is equilateral only if \( T \) is isosceles.
- For a triangle \( T \) to be isosceles, it is sufficient that \( T \) be equilateral.
- For a triangle \( T \) to be equilateral, it is necessary that \( T \) be isosceles.

Notice that at times we change the wording to make the statement or open sentence sound better. In general, the statement or open sentence \( P \) in the implication \( P \Rightarrow Q \) is commonly referred to as the **hypothesis** or **premise** of \( P \Rightarrow Q \), while \( Q \) is called the **conclusion** of \( P \Rightarrow Q \).

It is often easier to deal with an implication when expressed in an “if, then” form. This allows us to identify the hypothesis and conclusion more easily. Indeed, since implications can be stated in a wide variety of ways (even in addition to those mentioned above), being able to reword an implication as “if, then” is especially useful. For
2.5 More on Implications

example, the implication \( P(T) \Rightarrow Q(T) \) described in Example 2.8 can be encountered in many ways, including the following:

- Let \( T \) be an equilateral triangle. Then \( T \) is isosceles.
- Suppose that \( T \) is an equilateral triangle. Then \( T \) is isosceles.
- Every equilateral triangle is isosceles.
- Whenever a triangle is equilateral, it is isosceles.

We now investigate the truth or falseness of implications involving open sentences for values of their variables.

Example 2.9 Let \( S = \{2, 3, 5\} \) and let

\[
P(n): \ n^2 - n + 1 \text{ is prime. and } Q(n): \ n^3 - n + 1 \text{ is prime.}
\]

be open sentences over the domain \( S \). Determine the truth or falseness of the implication \( P(n) \Rightarrow Q(n) \) for each \( n \in S \).

Solution In this case, we have the following:

\[
P(2): \ 3 \text{ is prime. } P(3): \ 7 \text{ is prime. } P(5): \ 21 \text{ is prime.}
Q(2): \ 7 \text{ is prime. } Q(3): \ 25 \text{ is prime. } Q(5): \ 121 \text{ is prime.}
\]

Consequently, \( P(2) \Rightarrow Q(2) \) and \( P(5) \Rightarrow Q(5) \) are true, while \( P(3) \Rightarrow Q(3) \) is false.

Example 2.10 Let \( S = \{1, 2\} \) and let \( T = \{-1, 4\} \). Also, let

\[
P(x, y): \ ||x + y| - |x - y|| = 2 \text{ and } Q(x, y): \ x^{2+1} = y^4
\]

be open sentences, where the domain of the variable \( x \) is \( S \) and the domain of \( y \) is \( T \). Determine the truth or falseness of the implication \( P(x, y) \Rightarrow Q(x, y) \) for all \( (x, y) \in S \times T \).

Solution For \( (x, y) = (1, -1) \), we have

\[
P(1, -1) \Rightarrow Q(1, -1): \text{ If } 2 = 2, \text{ then } 1 = -1.
\]

which is false. For \( (x, y) = (1, 4) \), we have

\[
P(1, 4) \Rightarrow Q(1, 4): \text{ If } 2 = 2, \text{ then } 1 = 4.
\]

which is also false. For \( (x, y) = (2, -1) \), we have

\[
P(2, -1) \Rightarrow Q(2, -1): \text{ If } 2 = 2, \text{ then } 1 = 1.
\]
which is true; while for \((x, y) = (2, 4)\), we have
\[
P(2, 4) \Rightarrow Q(2, 4): \text{If } 2 = 4, \text{ then } 32 = 16.
\]
which is true.

### SECTION 2.5 EXERCISES

**2.30.** Consider the open sentences \(P(n) : 5n + 3 \) is prime. and \(Q(n) : 7n + 1 \) is prime., both over the domain \(\mathbb{N} \).

(a) State \(P(n) \Rightarrow Q(n) \) in words.
(b) State \(P(2) \Rightarrow Q(2) \) in words. Is this statement true or false?
(c) State \(P(6) \Rightarrow Q(6) \) in words. Is this statement true or false?

**2.31.** In each of the following, two open sentences \(P(x)\) and \(Q(x)\) over a domain \(S\) are given. Determine the truth value of \(P(x) \Rightarrow Q(x)\) for each \(x \in S\).

(a) \(P(x) : |x| = 4; \ Q(x) : x = 4; \ S = \{-4, -3, 1, 4, 5\} \)
(b) \(P(x) : x^2 = 16; \ Q(x) : |x| = 4; \ S = \{-6, -4, 0, 3, 4, 8\} \)
(c) \(P(x) : x > 3; \ Q(x) : 4x - 1 > 12; \ S = \{0, 2, 3, 4, 6\} \)

**2.32.** In each of the following, two open sentences \(P(x)\) and \(Q(x)\) over a domain \(S\) are given. Determine all \(x \in S\) for which \(P(x) \Rightarrow Q(x)\) is a true statement.

(a) \(P(x) : x - 3 = 4; \ Q(x) : x \geq 8; \ S = \mathbb{R} \)
(b) \(P(x) : x^2 \geq 1; \ Q(x) : x \geq 1; \ S = \mathbb{R} \)
(c) \(P(x) : x^2 \geq 1; \ Q(x) : x \geq 1; \ S = \mathbb{N} \)
(d) \(P(x) : x \in [-1, 2]; \ Q(x) : x^2 \leq 2; \ S = [-1, 1] \)

**2.33.** In each of the following, two open sentences \(P(x, y)\) and \(Q(x, y)\) are given, where the domain of both \(x\) and \(y\) is \(\mathbb{Z}\). Determine the truth value of \(P(x, y) \Rightarrow Q(x, y)\) for the given values of \(x\) and \(y\).

(a) \(P(x, y) : x^2 - y^2 = 0,\) and \(Q(x, y) : x = y.\)
\((x, y) \in \{(1, -1), (3, 4), (5, 5)\} \)
(b) \(P(x, y) : |x| = |y|,\) and \(Q(x, y) : x = y.\)
\((x, y) \in \{(1, 2), (2, -2), (6, 6)\} \)
(c) \(P(x, y) : x^2 + y^2 = 1,\) and \(Q(x, y) : x + y = 1.\)
\((x, y) \in \{(1, -1), (-3, 4), (0, -1), (1, 0)\} \)

**2.34.** Each of the following describes an implication. Write the implication in the form “if, then.”

(a) Any point on the straight line with equation \(2y + x - 3 = 0\) whose \(x\)-coordinate is an integer also has an integer for its \(y\)-coordinate.
(b) The square of every odd integer is odd.
(c) Let \(n \in \mathbb{Z}\). Whenever \(3n + 7\) is even, \(n\) is odd.
(d) The derivative of the function \(f(x) = \cos x\) is \(f'(x) = -\sin x\).
(e) Let \(C\) be a circle of circumference \(4\pi\). Then the area of \(C\) is also \(4\pi\).
(f) The integer \(n^3\) is even only if \(n\) is even.
2.6 BIBICONDITIONALS

For statements (or open sentences) $P$ and $Q$, the implication $Q \Rightarrow P$ is called the **converse** of $P \Rightarrow Q$. The converse of an implication will often be of interest to us, either by itself or in conjunction with the original implication.

**Example 2.11** For the statements

$P_1$: 3 is an odd integer.  
$P_2$: 57 is prime.

the converse of the implication

$P_1 \Rightarrow P_2$: If 3 is an odd integer, then 57 is prime.

is the implication

$P_2 \Rightarrow P_1$: If 57 is prime, then 3 is an odd integer. ♦

For statements (or open sentences) $P$ and $Q$, the conjunction

$$(P \Rightarrow Q) \land (Q \Rightarrow P)$$

of the implication $P \Rightarrow Q$ and its converse is called the **biconditional** of $P$ and $Q$ and is denoted by $P \Leftrightarrow Q$. For statements $P$ and $Q$, the truth table for $P \Leftrightarrow Q$ can therefore be determined. This is given in Figure 2.9. From this table, we see that $P \Leftrightarrow Q$ is true whenever the statements $P$ and $Q$ are both true or are both false, while $P \Leftrightarrow Q$ is false otherwise. That is, $P \Leftrightarrow Q$ is true precisely when $P$ and $Q$ have the same truth values.

![Truth Table for Biconditional](image)

**Figure 2.9** The truth table for a biconditional
Chapter 2  Logic

The biconditional \( P \iff Q \) is often stated as

\[
P \text{ is equivalent to } Q.
\]

or

\[
P \text{ if and only if } Q.
\]

or as

\[
P \text{ is necessary and sufficient for } Q.
\]

For statements \( P \) and \( Q \), it then follows that the biconditional “\( P \) if and only if \( Q \)” is true only when \( P \) and \( Q \) have the same truth values.

Example 2.12  The biconditional

\[
3 \text{ is an odd integer if and only if } 57 \text{ is prime.}
\]

is false; while the biconditional

\[
100 \text{ is even if and only if } 101 \text{ is prime.}
\]

is true. Furthermore, the biconditional

\[
5 \text{ is even if and only if } 4 \text{ is odd.}
\]

is also true.

The phrase “if and only if” occurs often in mathematics and we shall discuss this at greater length later. For the present, we consider two examples involving statements containing the phrase “if and only if.”

Example 2.13  We noted in Example 2.7 that for the open sentences

\[
P_1(x) : x = -3. \text{ and } P_2(x) : |x| = 3.
\]

over the domain \( \mathbb{R} \), the implication

\[
P_1(x) \Rightarrow P_2(x) : \text{If } x = -3, \text{ then } |x| = 3.
\]

is a true statement for each \( x \in \mathbb{R} \). However, the converse

\[
P_2(x) \Rightarrow P_1(x) : \text{If } |x| = 3, \text{ then } x = -3.
\]

is a false statement when \( x = 3 \) since \( P_2(3) \) is true and \( P_1(3) \) is false. For all other real numbers \( x \), the implication \( P_2(x) \Rightarrow P_1(x) \) is true. Therefore, the biconditional

\[
P_1(x) \iff P_2(x) : x = -3 \text{ if and only if } |x| = 3.
\]

is false when \( x = 3 \) and is true for all other real numbers \( x \).
Example 2.14  For the open sentences

\[ P(T) : T \text{ is equilateral. and } Q(T) : T \text{ is isosceles.} \]

over the domain \( S \) of all triangles, the converse of the implication

\[ P(T) \Rightarrow Q(T) : \text{If } T \text{ is equilateral, then } T \text{ is isosceles.} \]

is the implication

\[ Q(T) \Rightarrow P(T) : \text{If } T \text{ is isosceles, then } T \text{ is equilateral.} \]

We noted that \( P(T) \Rightarrow Q(T) \) is a true statement for all triangles \( T \), while \( Q(T) \Rightarrow P(T) \) is a false statement when \( T \) is an isosceles triangle that is not equilateral. On the other hand, the second implication becomes a true statement for all other triangles \( T \). Therefore, the biconditional

\[ P(T) \iff Q(T) : T \text{ is equilateral if and only if } T \text{ is isosceles.} \]

is false for all triangles that are isosceles and not equilateral, while it is true for all other triangles \( T \).

We now investigate the truth or falseness of biconditionals obtained by assigning to a variable each value in its domain.

Example 2.15  Let \( S = \{0, 1, 4\} \). Consider the following open sentences over the domain \( S \):

\[ P(n) : \frac{n(n+1)(2n+1)}{6} \text{ is odd.} \]

\[ Q(n) : (n + 1)^3 = n^3 + 1. \]

Determine three distinct elements \( a, b, c \) in \( S \) such that \( P(a) \Rightarrow Q(a) \) is false, \( Q(b) \Rightarrow P(b) \) is false and \( P(c) \iff Q(c) \) is true.

Solution  Observe that

\[ P(0) : 0 \text{ is odd. } P(1) : 1 \text{ is odd. } P(4) : 30 \text{ is odd.} \]

\[ Q(0) : 1 = 1. \quad Q(1) : 8 = 2. \quad Q(4) : 125 = 65. \]

Thus, \( P(0) \) and \( P(4) \) are false, while \( P(1) \) is true. Also, \( Q(1) \) and \( Q(4) \) are false, while \( Q(0) \) is true. Thus, \( P(1) \Rightarrow Q(1) \) and \( Q(0) \Rightarrow P(0) \) are false, while \( P(4) \iff Q(4) \) is true. Hence, we may take \( a = 1, b = 0 \) and \( c = 4 \).

Analysis  Notice in Example 2.15 that both \( P(0) \iff Q(0) \) and \( P(1) \iff Q(1) \) are false biconditionals. Hence, the value 4 in \( S \) is the only choice for \( c \).
SECTION 2.6 EXERCISES

2.35. Let \( P \): 18 is odd and \( Q \): 25 is even. State \( P \iff Q \) in words. Is \( P \iff Q \) true or false?

2.36. Let \( P(x) : x \) is odd and \( Q(x) : x^2 \) is odd be open sentences over the domain \( \mathbb{Z} \). State \( P(x) \iff Q(x) \) in two ways: (1) using “if and only if” and (2) using “necessary and sufficient.”

2.37. For the open sentences \( P(x) : |x - 3| < 1 \) and \( Q(x) : x \in (2, 4) \), over the domain \( \mathbb{R} \), state the biconditional \( P(x) \iff Q(x) \) in two different ways.

2.38. Consider the open sentences:

\[ P(x) : x = -2. \text{ and } Q(x) : x^2 = 4. \]

over the domain \( S = \{-2, 0, 2\} \). State each of the following in words and determine all values of \( x \in S \) for which the resulting statements are true.

- \( P(x) \)
- \( P(x) \lor Q(x) \)
- \( P(x) \land Q(x) \)
- \( P(x) \rightarrow Q(x) \)
- \( Q(x) \rightarrow P(x) \)
- \( P(x) \leftrightarrow Q(x) \).

2.39. For the following open sentences \( P(x) \) and \( Q(x) \) over a domain \( S \), determine all values of \( x \in S \) for which the biconditional \( P(x) \iff Q(x) \) is true.

- \( P(x) : |x| = 4; Q(x) : x = 4; S = \{-4, -3, 1, 4, 5\} \)
- \( P(x) : x \geq 3; Q(x) : 4x - 1 > 12; S = \{0, 2, 3, 4, 6\} \)
- \( P(x) : x^2 = 16; Q(x) : x^2 - 4x = 0; S = \{-6, -4, 0, 3, 4, 8\} \)

2.40. In each of the following, two open sentences \( P(x, y) \) and \( Q(x, y) \) are given, where the domain of both \( x \) and \( y \) is \( \mathbb{Z} \). Determine the truth value of \( P(x, y) \iff Q(x, y) \) for the given values of \( x \) and \( y \).

- \( P(x, y) : x^2 - y^2 = 0 \text{ and } Q(x, y) : x = y \)
  - \((x, y) \in \{(1, -1), (3, 4), (5, 5)\} \)
- \( P(x, y) : |x| = |y| \text{ and } Q(x, y) : x = y \)
  - \((x, y) \in \{(1, 2), (2, -2), (6, 6)\} \)
- \( P(x, y) : x^2 + y^2 = 1 \text{ and } Q(x, y) : x + y = 1 \)
  - \((x, y) \in \{(1, -1), (-3, 4), (0, -1), (1, 0)\} \)

2.41. Determine all values of \( n \) in the domain \( S = \{1, 2, 3\} \) for which the following is a true statement:
- A necessary and sufficient condition for \( \frac{n^2 + n}{2} \) to be even is that \( \frac{n^2 + n}{2} \) is odd.

2.42. Determine all values of \( n \) in the domain \( S = \{2, 3, 4\} \) for which the following is a true statement:
- The integer \( \frac{2n(n+1)}{2} \) is odd if and only if \( \frac{2n(n+1)}{2} \) is even.

2.43. Let \( S = \{1, 2, 3\} \). Consider the following open sentences over the domain \( S \):

\[ P(n) : \frac{(n+4)(n+5)}{2} \text{ is odd.} \]
\[ Q(n) : 2^{n-2} + 3^{n-2} + 6^{n-2} > (2.5)^{n-1}. \]

Determine three distinct elements \( a, b, c \) in \( S \) such that \( P(a) \Rightarrow Q(a) \) is false, \( Q(b) \Rightarrow P(b) \) is false and \( P(c) \iff Q(c) \) is true.

2.44. Let \( S = \{1, 2, 3, 4\} \). Consider the following open sentences over the domain \( S \):

\[ P(n) : \frac{n(n-1)}{2} \text{ is even.} \]
\[ Q(n) : 2^{n-2} - (-2)^{n-2} \text{ is even.} \]
\[ R(n) : 5^{n-1} + 2^n \text{ is prime.} \]
Determine four distinct elements \( a, b, c, d \) in \( S \) such that

(i) \( P(a) \Rightarrow Q(a) \) is false;  
(ii) \( Q(b) \Rightarrow P(b) \) is true;  
(iii) \( P(c) \Leftrightarrow R(c) \) is true;  
(iv) \( Q(d) \Leftrightarrow R(d) \) is false.

2.45. Let \( P(n) : 2^n - 1 \) is a prime. and \( Q(n) : n \) is a prime. be open sentences over the domain \( S = \{2, 3, 4, 5, 6, 11\} \). Determine all values of \( n \in S \) for which \( P(n) \Leftrightarrow Q(n) \) is a true statement.

2.7 TAUTOLOGIES AND CONTRADICTIONS

The symbols \( \neg, \lor, \land, \Rightarrow \) and \( \Leftrightarrow \) are sometimes referred to as logical connectives. From given statements, we can use these logical connectives to form more intricate statements. For example, the statement \( (P \lor Q) \land (P \lor R) \) is a statement formed from the given statements \( P, Q \) and \( R \) and the logical connectives \( \lor \) and \( \land \). We call \( (P \lor Q) \land (P \lor R) \) a compound statement. More generally, a compound statement is a statement composed of one or more given statements (called component statements in this context) and at least one logical connective. For example, for a given component statement \( P \), its negation \( \neg P \) is a compound statement.

The compound statement \( P \lor (\neg P) \), whose truth table is given in Figure 2.10, has the feature that it is true regardless of the truth value of \( P \).

\[
\begin{array}{ccc}
P & \neg P & P \lor (\neg P) \\
T & F & T \\
F & T & T \\
\end{array}
\]

**Figure 2.10** An example of a tautology

A compound statement \( S \) is called a tautology if it is true for all possible combinations of truth values of the component statements that comprise \( S \). Hence, \( P \lor (\neg P) \) is a tautology.

**Example 2.16** For statements \( P \) and \( Q \), the compound statement \( (\neg Q) \lor (P \Rightarrow Q) \) is a tautology, as is verified in the truth table shown in Figure 2.11.

\[
\begin{array}{cccc}
P & Q & \neg Q & P \Rightarrow Q & (\neg Q) \lor (P \Rightarrow Q) \\
T & T & F & T & T \\
T & F & T & F & T \\
F & T & F & T & T \\
F & F & T & T & T \\
\end{array}
\]

**Figure 2.11** Verifying that \( (\neg Q) \lor (P \Rightarrow Q) \) is a tautology

Letting

\[ P_1 : 3 \text{ is odd, and } P_2 : 57 \text{ is prime.} \]
Chapter 2  Logic

we see that not only is

57 is not prime, or 57 is prime if 3 is odd.

a true statement, but \((\sim P_2) \lor (P_1 \Rightarrow P_2)\) is true regardless of which statements \(P_1\) and \(P_2\) are being considered.

On the other hand, a compound statement \(S\) is called a contradiction if it is false for all possible combinations of truth values of the component statements that are used to form \(S\). The statement \(P \land (\sim P)\) is a contradiction, as is shown in Figure 2.12. Hence, the statement

\[
3 \text{ is odd and } 3 \text{ is not odd.}
\]

is false.

\[
\begin{array}{ccc}
P & \sim P & P \land (\sim P) \\
T & F & F \\
F & T & F \\
\end{array}
\]

Figure 2.12  An example of a contradiction

Example 2.17  For statements \(P\) and \(Q\), the compound statement

\[
(P \land Q) \land (Q \Rightarrow (\sim P))
\]

is a contradiction, which is verified in the truth table shown in Figure 2.13.

\[
\begin{array}{cccc}
P & Q & \sim P & P \land Q \land (Q \Rightarrow (\sim P)) \\
T & T & F & T \\
T & F & F & T \\
F & T & T & T \\
F & F & T & T \\
\end{array}
\]

Figure 2.13  Verifying that \((P \land Q) \land (Q \Rightarrow (\sim P))\) is a contradiction

Indeed, if a compound statement \(S\) is a tautology, then its negation \(\sim S\) is a contradiction.

Example 2.18  For statements \(P\) and \(Q\), determine whether the compound statement

\[
(P \land Q) \Rightarrow (P \lor Q)
\]

is a tautology, a contradiction or neither.

Solution  The truth table in Figure 2.14 shows that the compound statement \((P \land Q) \Rightarrow (P \lor Q)\) is a tautology.

\[
\begin{array}{cccc}
P & Q & \sim P & P \land Q \Rightarrow (P \lor Q) \\
T & T & F & T \\
T & F & F & T \\
F & T & T & T \\
F & F & T & T \\
\end{array}
\]

Figure 2.14  A truth table for \((P \land Q) \Rightarrow (P \lor Q)\)

\[
\sim S
\]

Section 2.7 Exercises

2.7 Exercises

Example 2.19 For statements $P$ and $Q$, determine whether the compound statement

$$(P \land \sim Q) \iff (P \Rightarrow Q)$$

is a tautology, a contradiction or neither.

Solution The truth table in Figure 2.15 shows that the compound statement $(P \land \sim Q) \iff (P \Rightarrow Q)$ is a contradiction.

![Truth Table](image)

Figure 2.15 Verifying that $(P \land \sim Q) \iff (P \Rightarrow Q)$ is a contradiction

SECTION 2.7 EXERCISES

2.46. For statements $P$ and $Q$, show that $P \Rightarrow (P \lor Q)$ is a tautology.

2.47. For statements $P$ and $Q$, show that $(P \land \sim Q) \land (P \land Q)$ and $(P \Rightarrow \sim Q) \land (P \land Q)$ are contradictions.

2.48. For statements $P$ and $Q$, show that $(P \land (P \Rightarrow Q)) \Rightarrow Q$ is a tautology. Then state $(P \land (P \Rightarrow Q)) \Rightarrow Q$ in words. (This is an important logical argument form, called modus ponens.)

2.49. For statements $P$, $Q$, and $R$, show that $((P \Rightarrow Q) \land (Q \Rightarrow R)) \Rightarrow (P \Rightarrow R)$ is a tautology. Then state this compound statement in words. (This is another important logical argument form, called syllogism.)

2.50. Let $R$ and $S$ be compound statements involving the same component statements. If $R$ is a tautology and $S$ is a contradiction, then what can be said of the following?

(a) $R \lor S$  (b) $R \land S$  (c) $R \Rightarrow S$  (d) $S \Rightarrow R$.

2.51. For statements $P$ and $Q$, determine whether the compound statement $(P \lor Q) \lor (Q \Rightarrow P)$ is a tautology, a contradiction or neither.

2.52. For statements $P$ and $Q$, determine whether the compound statement $((P \Rightarrow Q) \Rightarrow P \Rightarrow (P \Rightarrow Q))$ is a tautology, a contradiction or neither.
2.8 LOGICAL EQUIVALENCE

Figure 2.16 shows a truth table for the two statements $P \Rightarrow Q$ and $(\sim P) \lor Q$. The corresponding columns of these compound statements are identical; in other words, these two compound statements have exactly the same truth value for every combination of truth values of the statements $P$ and $Q$. Let $R$ and $S$ be two compound statements involving the same component statements. Then $R$ and $S$ are called **logically equivalent** if $R$ and $S$ have the same truth values for all combinations of truth values of their component statements. If $R$ and $S$ are logically equivalent, then this is denoted by $R \equiv S$. Hence, $P \Rightarrow Q$ and $(\sim P) \lor Q$ are logically equivalent and so $P \Rightarrow Q \equiv (\sim P) \lor Q$.

\[
\begin{array}{cccc}
P & Q & \sim P & P \Rightarrow Q & (\sim P) \lor Q \\
T & T & F & T & T \\
T & F & F & F & F \\
F & T & T & T & T \\
F & F & T & T & T \\
\end{array}
\]

**Figure 2.16** Verification of $P \Rightarrow Q \equiv (\sim P) \lor Q$

Another, even simpler example of logical equivalence concerns $P \land Q$ and $Q \land P$. That $P \land Q \equiv Q \land P$ is verified in the truth table shown in Figure 2.17.

\[
\begin{array}{cccc}
P & Q & P \land Q & Q \land P \\
T & T & T & T \\
T & F & F & F \\
F & T & F & F \\
F & F & F & F \\
\end{array}
\]

**Figure 2.17** Verification of $P \land Q \equiv Q \land P$

What is the practical significance of logical equivalence? Suppose that $R$ and $S$ are logically equivalent compound statements. Then we know that $R$ and $S$ have the same truth values for all possible combinations of truth values of their component statements. But this means that the biconditional $R \iff S$ is true for all possible combinations of truth values of their component statements and hence $R \iff S$ is a tautology. Conversely, if $R \iff S$ is a tautology, then $R$ and $S$ are logically equivalent.

Let $R$ be a mathematical statement that we would like to show is true and suppose that $R$ and some statement $S$ are logically equivalent. If we can show that $S$ is true, then $R$ is true as well. For example, suppose that we want to verify the truth of an implication $P \Rightarrow Q$. If we can establish the truth of the statement $(\sim P) \lor Q$, then the logical equivalence of $P \Rightarrow Q$ and $(\sim P) \lor Q$ guarantees that $P \Rightarrow Q$ is true as well.
Example 2.20  Let’s return to Example 2.6 and whether a certain mathematics instructor kept her promise that

*If you earn an A on the final exam, then you will receive an A for the final grade.*

We need only know that the student did not receive an A on the final exam or the student received an A as a final grade to see that the instructor kept her promise. ♦

Since the logical equivalence of \( P \Rightarrow Q \) and \((\sim P) \lor Q\), verified in Figure 2.16, is especially important and we will have occasion to use this fact often, we state it as a theorem.

Theorem 2.21 Let \( P \) and \( Q \) be two statements. Then

\[ P \Rightarrow Q \text{ and } (\sim P) \lor Q \]

are logically equivalent.

Let’s return to the truth table in Figure 2.17, where we showed that \( P \land Q \) and \( Q \land P \) are logically equivalent for any two statements \( P \) and \( Q \). In particular, this says that

\[ (P \Rightarrow Q) \land (Q \Rightarrow P) \text{ and } (Q \Rightarrow P) \land (P \Rightarrow Q) \]

are logically equivalent. Of course, \((P \Rightarrow Q) \land (Q \Rightarrow P)\) is precisely what is called the biconditional of \( P \) and \( Q \). Since \((P \Rightarrow Q) \land (Q \Rightarrow P)\) and \((Q \Rightarrow P) \land (P \Rightarrow Q)\) are logically equivalent, \((Q \Rightarrow P) \land (P \Rightarrow Q)\) represents the biconditional of \( P \) and \( Q \) as well. Since \( Q \Rightarrow P \) can be written as “\( P \) if \( Q \)” and \( P \Rightarrow Q \) can be expressed as “\( P \) only if \( Q \)” their conjunction can be written as “\( P \) if \( Q \) and \( P \) only if \( Q \)” or, more simply, as

\( P \) if and only if \( Q \).

Consequently, expressing \( P \Leftrightarrow Q \) as “\( P \) if and only if \( Q \)” is justified. Furthermore, since \( Q \Rightarrow P \) can be phrased as “\( P \) is necessary for \( Q \)” and \( P \Rightarrow Q \) can be expressed as “\( P \) is sufficient for \( Q \)” writing \( P \Leftrightarrow Q \) as “\( P \) is necessary and sufficient for \( Q \)” is likewise justified.

**SECTION 2.8 EXERCISES**

2.53. For statements \( P \) and \( Q \), the implication \((\sim P) \Rightarrow (\sim Q)\) is called the **inverse** of the implication of \( P \Rightarrow Q \).
   (a) Use a truth table to show that these implications are not logically equivalent.
   (b) Find another implication that is logically equivalent to \((\sim P) \Rightarrow (\sim Q)\) and verify your answer.

2.54. Let \( P \) and \( Q \) be statements.
   (a) Is \((\sim P \lor Q)\) logically equivalent to \((\sim P) \lor (\sim Q)\)? Explain.
   (b) What can you say about the biconditional \((\sim P \lor Q) \Leftrightarrow ((\sim P) \lor (\sim Q))\)?

2.55. For statements \( P, Q \) and \( R \), use a truth table to show that each of the following pairs of statements are logically equivalent.
   (a) \((P \land Q) \Leftrightarrow P \text{ and } P \Rightarrow Q\).
   (b) \(P \Rightarrow (Q \lor R) \text{ and } (\sim Q) \Rightarrow ((\sim P) \lor R)\).
2.56. For statements $P$ and $Q$, show that $(\sim Q) \Rightarrow (P \land (\sim P))$ and $Q$ are logically equivalent.

2.57. For statements $P$, $Q$ and $R$, show that $(P \lor Q) \Rightarrow R$ and $(P \Rightarrow R) \land (Q \Rightarrow R)$ are logically equivalent.

2.58. Two compound statements $S$ and $T$ are comprised of the same component statements $P$, $Q$ and $R$. If $S$ and $T$ are not logically equivalent, then what can we conclude from this?

2.59. Five compound statements $S_1$, $S_2$, $S_3$, $S_4$ and $S_5$ are all comprised of the same component statements $P$ and $Q$ whose truth tables have identical first and fourth rows. Show that at least two of these five statements are logically equivalent.

2.9 SOME FUNDAMENTAL PROPERTIES OF LOGICAL EQUIVALENCE

It probably comes as no surprise that the statements $P$ and $\sim (\sim P)$ are logically equivalent. This fact is verified in Figure 2.18.

<table>
<thead>
<tr>
<th>$P$</th>
<th>$\sim P$</th>
<th>$\sim (\sim P)$</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>F</td>
<td>T</td>
</tr>
<tr>
<td>F</td>
<td>T</td>
<td>F</td>
</tr>
</tbody>
</table>

Figure 2.18 Verification of $P \equiv \sim (\sim P)$

We mentioned in Figure 2.17 that, for two statements $P$ and $Q$, the statements $P \land Q$ and $Q \land P$ are logically equivalent. There are other fundamental logical equivalences that we often encounter as well.

**Theorem 2.22** For statements $P$, $Q$ and $R$,

1. **Commutative Laws**
   - (a) $P \lor Q \equiv Q \lor P$.
   - (b) $P \land Q \equiv Q \land P$.

2. **Associative Laws**
   - (a) $P \lor (Q \lor R) \equiv (P \lor Q) \lor R$.
   - (b) $P \land (Q \land R) \equiv (P \land Q) \land R$.

3. **Distributive Laws**
   - (a) $P \lor (Q \land R) \equiv (P \lor Q) \land (P \lor R)$.
   - (b) $P \land (Q \lor R) \equiv (P \land Q) \lor (P \land R)$.

4. **De Morgan’s Laws**
   - (a) $\sim (P \lor Q) \equiv (\sim P) \land (\sim Q)$.
   - (b) $\sim (P \land Q) \equiv (\sim P) \lor (\sim Q)$.

Each part of Theorem 2.22 can be verified by means of a truth table. We have already established the commutative law for conjunction (namely $P \land Q \equiv Q \land P$) in Figure 2.17. In Figure 2.19 $P \lor (Q \land R) \equiv (P \lor Q) \land (P \lor R)$ is verified by observing that
the columns corresponding to the statements \( P \lor (Q \land R) \) and \( (P \lor Q) \land (P \lor R) \) are identical.

\[
\begin{array}{cccccccc}
P & Q & R & Q \land R & P \lor Q & P \lor R & P \lor (Q \land R) & (P \lor Q) \land (P \lor R) \\
T & T & T & T & T & T & T & T \\
T & T & F & F & T & T & T & T \\
T & F & T & F & T & T & T & T \\
T & F & F & F & T & T & T & T \\
F & T & T & T & T & T & T & T \\
F & T & F & F & T & F & F & F \\
F & F & T & F & F & F & F & F \\
F & F & F & F & F & F & F & F \\
\end{array}
\]

Figure 2.19 Verification of the distributive law \( P \lor (Q \land R) \equiv (P \lor Q) \land (P \lor R) \)

The laws given in Theorem 2.22 together with other known logical equivalences can be used to good advantage at times to prove other logical equivalences (without introducing a truth table).

**Example 2.23** Suppose that we are asked to verify

\[
\neg (P \Rightarrow Q) \equiv P \land (\neg Q)
\]

for every two statements \( P \) and \( Q \). Using the logical equivalence of \( P \Rightarrow Q \) and \( (\neg P) \lor Q \) from Theorem (2.21) and Theorem 2.22(4a), we see that

\[
\neg (P \Rightarrow Q) \equiv \neg ((\neg P) \lor Q) \equiv (\neg (\neg P)) \land (\neg Q) \equiv P \land (\neg Q), \tag{2.1}
\]

implying that the statements \( \neg (P \Rightarrow Q) \) and \( P \land (\neg Q) \) are logically equivalent, which we alluded to earlier.

It is important to keep in mind what we have said about logical equivalence. For example, the logical equivalence of \( P \land Q \) and \( Q \land P \) allows us to replace a statement of the type \( P \land Q \) by \( Q \land P \) without changing its truth value. As an additional example, according to De Morgan’s Laws in Theorem 2.22, if it is not the case that an integer \( a \) is even or an integer \( b \) is even, then it follows that \( a \) and \( b \) are both odd.

**Example 2.24** Using the second of De Morgan’s Laws and (2.1), we can establish a useful logically equivalent form of the negation of \( P \Leftrightarrow Q \) by the following string of logical equivalences:

\[
\neg (P \Leftrightarrow Q) \equiv \neg ((P \Rightarrow Q) \land (Q \Rightarrow P))
\equiv (\neg (P \Rightarrow Q)) \lor (\neg (Q \Rightarrow P))
\equiv (P \land (\neg Q)) \lor (Q \land (\neg P)). \tag{2.2}
\]
What we have observed about the negation of an implication and a biconditional is repeated in the following theorem.

**Theorem 2.25** For statements $P$ and $Q$.

(a) $\sim(P \Rightarrow Q) \equiv P \land (\sim Q)$.

(b) $\sim(P \iff Q) \equiv (P \land (\sim Q)) \lor (Q \land (\sim P))$.

**Example 2.26** Once again, let's return to what the mathematics instructor in Example 2.6 said:

*If you earn an A on the final exam, then you will receive an A for your final grade.*

If this instructor was not truthful, then it follows by Theorem 2.25(a) that

*You earned an A on the final exam and did not receive A as your final grade.*

Suppose, on the other hand, that the mathematics instructor had said:

*If you earn an A on the final exam, then you will receive an A for the final grade – and that’s the only way that you will get an A for a final grade.*

If this instructor was not truthful, then it follows by Theorem 2.25(b) that

*Either you earned an A on the final exam and didn’t receive A as your final grade or you received an A for your final grade and you didn’t get an A on the final exam.*

♦

**SECTION 2.9 EXERCISES**

2.60. Verify the following laws stated in Theorem 2.22:

(a) Let $P$, $Q$ and $R$ be statements. Then

$P \lor (Q \land R)$ and $(P \lor Q) \land (P \lor R)$ are logically equivalent.

(b) Let $P$ and $Q$ be statements. Then

$\sim(P \lor Q)$ and $(\sim P) \land (\sim Q)$ are logically equivalent.

2.61. Write negations of the following open sentences:

(a) Either $x = 0$ or $y = 0$.

(b) The integers $a$ and $b$ are both even.

2.62. Consider the implication: If $x$ and $y$ are even, then $xy$ is even.

(a) State the implication using “only if.”

(b) State the converse of the implication.

(c) State the implication as a disjunction (see Theorem 2.21).

(d) State the negation of the implication as a conjunction (see Theorem 2.25(a)).

2.63. For a real number $x$, let $P(x) : x^2 = 2$. and $Q(x) : x = \sqrt{2}$. State the negation of the biconditional $P \iff Q$ in words (see Theorem 2.25(b)).

2.64. Let $P$ and $Q$ be statements. Show that $[(P \lor Q) \land \sim(P \land Q)] \equiv \sim(P \iff Q)$. 
2.65. Let \( n \in \mathbb{Z} \). For which implication is its negation the following?

The integer \( 3n + 4 \) is odd and \( 5n - 6 \) is even.

2.66. For which biconditional is its negation the following?

\( n^3 \) and \( 7n + 2 \) are odd or \( n^3 \) and \( 7n + 2 \) are even.

### 2.10 QUANTIFIED STATEMENTS

We have mentioned that if \( P(x) \) is an open sentence over a domain \( S \), then \( P(x) \) is a statement for each \( x \in S \). We illustrate this again.

**Example 2.27** If \( S = \{1, 2, \ldots, 7\} \), then

\[
P(n) : \frac{2n^2 + 5 + (-1)^n}{2}
\]

is a statement for each \( n \in S \). Therefore,

\[
P(1) : 3 \text{ is prime.} \\
P(2) : 7 \text{ is prime.} \\
P(3) : 11 \text{ is prime.} \\
P(4) : 19 \text{ is prime.}
\]

are true statements; while

\[
P(5) : 27 \text{ is prime.} \\
P(6) : 39 \text{ is prime.} \\
P(7) : 51 \text{ is prime.}
\]

are false statements.

There are other ways that an open sentence can be converted into a statement, namely by a method called quantification. Let \( P(x) \) be an open sentence over a domain \( S \). Adding the phrase “For every \( x \in S \)” to \( P(x) \) produces a statement called a **quantified statement**. The phrase “for every” is referred to as the universal quantifier and is denoted by the symbol \( \forall \). Other ways to express the universal quantifier are “for each” and “for all.” This quantified statement is expressed in symbols by

\[
\forall x \in S, P(x) \quad (2.2)
\]

and is expressed in words by

For every \( x \in S \), \( P(x) \).

(2.3)

The quantified statement (2.2) (or (2.3)) is true if \( P(x) \) is true for every \( x \in S \); while the quantified statement (2.2) is false if \( P(x) \) is false for at least one element \( x \in S \).

Another way to convert an open sentence \( P(x) \) over a domain \( S \) into a statement through quantification is by the introduction of a quantifier called an existential quantifier. Each of the phrases “there exists,” “there is,” “for some,” and “for at least one” is
Chapter 2  Logic

referred to as an existential quantifier and is denoted by the symbol \( \exists \). The quantified statement

\[
\exists x \in S, P(x)
\]  \hspace{1cm} (2.4)

can be expressed in words by

There exists \( x \in S \) such that \( P(x) \).

(2.5)

The quantified statement (2.4) (or (2.5)) is true if \( P(x) \) is true for at least one element \( x \in S \); while the quantified statement (2.4) is false if \( P(x) \) is false for all \( x \in S \).

We now consider two quantified statements constructed from the open sentence we saw in Example 2.27.

Example 2.28  For the open sentence

\[
P(n) : \frac{2n^2 + 5 + (-1)^n}{2}
\]

is prime.

over the domain \( S = \{1, 2, \ldots, 7\} \), the quantified statement

\[
\forall n \in S, P(n): \text{For every } n \in S, \frac{2n^2 + 5 + (-1)^n}{2} \text{ is prime.}
\]

is false since \( P(5) \) is false, for example; while the quantified statement

\[
\exists n \in S, P(n): \text{There exists } n \in S \text{ such that } \frac{2n^2 + 5 + (-1)^n}{2} \text{ is prime.}
\]

is true since \( P(1) \) is true, for example.

The quantified statement \( \forall x \in S, P(x) \) can also be expressed as

If \( x \in S \), then \( P(x) \).

Consider the open sentence \( P(x) : x^2 \geq 0 \). over the set \( \mathbb{R} \) of real numbers. Then

\[
\forall x \in \mathbb{R}, P(x)
\]

or, equivalently,

\[
\forall x \in \mathbb{R}, x^2 \geq 0
\]

can be expressed as

For every real number \( x \), \( x^2 \geq 0 \).

or

If \( x \) is a real number, then \( x^2 \geq 0 \).

as well as

The square of every real number is nonnegative.
In general, the universal quantifier is used to claim that the statement resulting from a given open sentence is true when each value of the domain of the variable is assigned to the variable. Consequently, the statement $\forall x \in \mathbb{R}, x^2 \geq 0$ is true since $x^2 \geq 0$ is true for every real number $x$.

Suppose now that we were to consider the open sentence $Q(x) : x^2 \leq 0$. The statement $\forall x \in \mathbb{R}, Q(x)$ (that is, for every real number $x$, we have $x^2 \leq 0$) is false since, for example, $Q(1)$ is false. Of course, this means that its negation is true. If it were not the case that for every real number $x$, we have $x^2 \leq 0$, then there must exist some real number $x$ such that $x^2 > 0$. This negation can be written in symbols as $\exists x \in \mathbb{R}, x^2 > 0$ or $\exists x \in \mathbb{R}, \sim Q(x)$.

More generally, if we are considering an open sentence $P(x)$ over a domain $S$, then

$$\sim (\forall x \in S, P(x)) \equiv \exists x \in S, \sim P(x).$$

### Example 2.29

Suppose that we are considering the set $A = \{1, 2, 3\}$ and its power set $\mathcal{P}(A)$, the set of all subsets of $A$. Then the quantified statement

$$\text{For every set } B \in \mathcal{P}(A), A - B \neq \emptyset. \quad (2.6)$$

is false since for the subset $B = A = \{1, 2, 3\}$, we have $A - B = \emptyset$. The negation of the statement (2.6) is

$$\text{There exists } B \in \mathcal{P}(A) \text{ such that } A - B = \emptyset. \quad (2.7)$$

The statement (2.7) is therefore true since for $B = A \in \mathcal{P}(A)$, we have $A - B = \emptyset$. The statement (2.6) can also be written as

$$\text{If } B \subseteq A, \text{ then } A - B \neq \emptyset. \quad (2.8)$$

Consequently, the negation of (2.8) can be expressed as

$$\text{There exists some subset } B \text{ of } A \text{ such that } A - B = \emptyset. \quad \blacklozenge$$

The existential quantifier is used to claim that at least one statement resulting from a given open sentence is true when the values of a variable are assigned from its domain. We know that for an open sentence $P(x)$ over a domain $S$, the quantified statement $\exists x \in S, P(x)$ is true provided $P(x)$ is a true statement for at least one element $x \in S$. Thus, the statement $\exists x \in \mathbb{R}, x^2 > 0$ is true since, for example, $x^2 > 0$ is true for $x = 1$.

The quantified statement

$$\exists x \in \mathbb{R}, 3x = 12$$

is therefore true since there is some real number $x$ for which $3x = 12$, namely $x = 4$ has this property. (Indeed, $x = 4$ is the only real number for which $3x = 12$.) On the other hand, the quantified statement

$$\exists n \in \mathbb{Z}, 4n - 1 = 0$$

is false since there is no integer $n$ for which $4n - 1$ is zero.
is false as there is no integer \( n \) for which \( 4n - 1 = 0 \). (Of course, \( 4n - 1 = 0 \) when \( n = 1/4 \), but \( 1/4 \) is not an integer.)

Suppose that \( Q(x) \) is an open sentence over a domain \( S \). If the statement \( \exists x \in S, Q(x) \) is not true, then it must be the case that for every \( x \in S \), \( Q(x) \) is false. That is,

\[
\sim (\exists x \in S, Q(x)) \equiv \forall x \in S, \sim Q(x)
\]

is true. We illustrate this with a specific example.

**Example 2.30**

The following statement contains the existential quantifier.

There exists a real number \( x \) such that \( x^2 = 3 \).

If we let \( P(x) : x^2 = 3 \), then (2.9) can be rewritten as \( \exists x \in \mathbb{R}, P(x) \). The statement (2.9) is true since \( P(x) \) is true when \( x = \sqrt{3} \) (or when \( x = -\sqrt{3} \)). Hence, the negation of (2.9) is:

\[
\text{For every real number } x, x^2 \neq 3.
\]

The statement (2.10) is therefore false.

Let \( P(x, y) \) be an open sentence, where the domain of the variable \( x \) is \( S \) and the domain of the variable \( y \) is \( T \). Then the quantified statement

For all \( x \in S \) and \( y \in T \), \( P(x, y) \).

can be expressed symbolically as

\[
\forall x \in S, \forall y \in T, P(x, y).
\]

The negation of the statement (2.11) is

\[
\sim (\forall x \in S, \forall y \in T, P(x, y)) \equiv \exists x \in S, \sim (\forall y \in T, P(x, y))
\]

\[
\equiv \exists x \in S, \exists y \in T, \sim P(x, y).
\]

We now consider examples of quantified statements involving two variables.

**Example 2.31**

Consider the statement

For every two real numbers \( x \) and \( y \), \( x^2 + y^2 \geq 0 \).

If we let

\[
P(x, y) : x^2 + y^2 \geq 0
\]

where the domain of both \( x \) and \( y \) is \( \mathbb{R} \), then statement (2.13) can be expressed as

\[
\forall x \in \mathbb{R}, \forall y \in \mathbb{R}, P(x, y)
\]

or as

\[
\forall y \in \mathbb{R}, \forall x \in \mathbb{R}, P(x, y)
\]
2.10 Quantified Statements

or as

\[ \forall x, y \in \mathbb{R}, \ P(x, y) \quad \text{or} \quad \forall y, x \in \mathbb{R}, \ P(x, y) \]

since quantifiers of the same type commute. Since \( x^2 \geq 0 \) and \( y^2 \geq 0 \) for all real numbers \( x \) and \( y \), it follows that \( x^2 + y^2 \geq 0 \) and so \( P(x, y) \) is true for all real numbers \( x \) and \( y \). Thus, the quantified statement (2.14) is true.

The negation of statement (2.14) is therefore

\[
\sim \left( \forall x \in \mathbb{R}, \forall y \in \mathbb{R}, \ P(x, y) \right) \equiv \exists x \in \mathbb{R}, \exists y \in \mathbb{R}, \ \sim P(x, y),
\]

which, in words, is

There exist real numbers \( x \) and \( y \) such that \( x^2 + y^2 < 0 \). (2.16)

The statement (2.16) is therefore false. ♦

For an open sentence containing two variables, the domains of the variables need not be the same.

Example 2.32 Consider the statement

For every \( s \in S \) and \( t \in T \), \( st + 2 \) is a prime. (2.17)

where the domain of the variable \( s \) is \( S = \{1, 3, 5\} \) and the domain of the variable \( t \) is \( T = \{3, 9\} \). If we let

\[ Q(s, t): \ st + 2 \text{ is a prime.} \]

then the statement (2.17) can be expressed as

\[ \forall s \in S, \forall t \in T, \ Q(s, t). \]  (2.18)

Since all of the statements

\[ Q(1, 3): \ 1 \cdot 3 + 2 \text{ is a prime.} \quad Q(3, 3): \ 3 \cdot 3 + 2 \text{ is a prime.} \]
\[ Q(5, 3): \ 5 \cdot 3 + 2 \text{ is a prime.} \]
\[ Q(1, 9): \ 1 \cdot 9 + 2 \text{ is a prime.} \quad Q(3, 9): \ 3 \cdot 9 + 2 \text{ is a prime.} \]
\[ Q(5, 9): \ 5 \cdot 9 + 2 \text{ is a prime.} \]

are true, the quantified statement (2.18) is true.

As we saw in (2.12), the negation of the quantified statement (2.18) is

\[
\sim \left( \forall s \in S, \forall t \in T, \ Q(s, t) \right) \equiv \exists s \in S, \exists t \in T, \ \sim Q(s, t)
\]

and so the negation of (2.17) is

There exist \( s \in S \) and \( t \in T \) such that \( st + 2 \) is not a prime. (2.19)

The statement (2.19) is therefore false. ♦
Again, let \( P(x, y) \) be an open sentence, where the domain of the variable \( x \) is \( S \) and the domain of the variable \( y \) is \( T \). The quantified statement

\[
\text{There exist } x \in S \text{ and } y \in T \text{ such that } P(x, y).
\]

can be expressed in symbols as

\[
\exists x \in S, \exists y \in T, P(x, y) \quad (2.20)
\]
or as

\[
\exists x \in S, y \in T, P(x, y) \quad \text{or} \quad \exists y \in T, x \in S, P(x, y).
\]
The negation of the statement (2.20) is then

\[
\sim (\exists x \in S, \exists y \in T, P(x, y)) \equiv \forall x \in S, \sim (\exists y \in T, P(x, y)) \equiv \forall x \in S, \forall y \in T, \sim P(x, y). \quad (2.21)
\]

We now illustrate this situation.

**Example 2.33** Consider the open sentence

\[
R(s, t): |s - 1| + |t - 2| \leq 2.
\]

where the domain of the variable \( s \) is the set \( S \) of even integers and the domain of the variable \( t \) is the set \( T \) of odd integers. Then the quantified statement

\[
\exists s \in S, \exists t \in T, R(s, t) \quad (2.22)
\]
can be expressed in words as

There exist an even integer \( s \) and an odd integer \( t \) such that \( |s - 1| + |t - 2| \leq 2. \quad (2.23)\)

Since \( R(2, 3): 1 + 1 \leq 2 \) is true, the quantified statement (2.23) is true.

The negation of (2.22) is therefore

\[
\sim (\exists s \in S, \exists t \in T, R(s, t)) \equiv \forall s \in S, \forall t \in T, \sim R(s, t) \quad (2.24)
\]
and so the negation of (2.22), in words, is

For every even integer \( s \) and every odd integer \( t \), \( |s - 1| + |t - 2| > 2. \quad (2.25)\)

The quantified statement (2.25) is therefore false.

In the next two examples of negations of quantified statements, De Morgan’s laws are also used.

**Example 2.34** The negation of

For all integers \( a \) and \( b \), if \( ab \) is even, then \( a \) is even and \( b \) is even.

is

There exist integers \( a \) and \( b \) such that \( ab \) is even and \( a \) or \( b \) is odd. ♦
Example 2.35  Let \( A = \{ \sqrt{2}, \pi \} \) and \( B = \{ -\sqrt{2}, \sqrt{3}, e \} \). The negation of

There exists a rational number \( r \) such that \( r \in A \) or \( r \in B \).

is

For every rational number \( r \), both \( r \notin A \) and \( r \notin B \). ♦

Quantified statements may contain both universal and existential quantifiers. While we present examples of these now, we will discuss these in more detail in Section 8.2.

Example 2.36  Consider the open sentence

\[ P(a, b) : ab = 1. \]

where the domain of both \( a \) and \( b \) is the set \( Q^+ \) of positive rational numbers. Then the quantified statement

\[ \forall a \in Q^+, \exists b \in Q^+, P(a, b). \quad (2.26) \]

can be expressed in words as

For every positive rational number \( a \), there exists a positive rational number \( b \) such that \( ab = 1 \).

It turns out that the quantified statement (2.26) is true. If we replace \( Q^+ \) by \( R \), then we have

\[ \forall a \in R, \exists b \in R, P(a, b). \quad (2.27) \]

The negation of this statement is

\[ \sim (\forall a \in R, \exists b \in R, P(a, b)) \equiv \exists a \in R, \sim (\exists b \in R, P(a, b)) \equiv \exists a \in R, \forall b \in R, \sim P(a, b), \]

which, in words, says that

There exists a real number \( a \) such that for every real number \( b \), \( ab \neq 1 \).

This negation is true since for \( a = 0 \) and every real number \( b \), \( ab = 0 \neq 1 \). Thus, the quantified statement (2.27) is false. ♦

Example 2.37  Consider the open sentence

\[ Q(a, b): ab \text{ is odd.} \]

where the domain of both \( a \) and \( b \) is the set \( N \) of positive integers. Then the quantified statement

\[ \exists a \in N, \forall b \in N, Q(a, b), \quad (2.28) \]
expressed in words, is

There exists a positive integer \(a\) such that for every positive integer \(b\), \(ab\) is odd.

The statement (2.28) turns out to be false. The negation of (2.28), in symbols, is

\[
\sim (\exists a \in \mathbb{N}, \forall b \in \mathbb{N}, Q(a, b)) \equiv \forall a \in \mathbb{N}, \sim (\forall b \in \mathbb{N}, Q(a, b)) \\
\equiv \forall a \in \mathbb{N}, \exists b \in \mathbb{N}, \sim Q(a, b).
\]

In words, this says

For every positive integer \(a\), there exists a positive integer \(b\) such that \(ab\) is even.

This statement, therefore, is true.

Example 2.38 Consider the open sentence

\[P(x, y): x + y \text{ is prime},\]

where the domain of \(x\) is \(S = \{2, 3\}\) and the domain of \(y\) is \(T = \{3, 4\}\). The quantified statement

\[\forall x \in S, \exists y \in T, P(x, y),\]

expressed in words, is

For every \(x \in S\), there exists \(y \in T\) such that \(x + y\) is prime.

This statement is true. For \(x = 2\), \(P(2, 3)\) is true and for \(x = 3\), \(P(3, 4)\) is true.

While two quantifiers of the same type commute, this is not the case for quantifiers of a different type.

Example 2.39 Once again, consider the open sentence

\[P(x, y): x + y \text{ is prime},\]

where the domain of \(x\) is \(S = \{2, 3\}\) and the domain of \(y\) is \(T = \{3, 4\}\). Here, we consider the quantified statement

\[\exists y \in T, \forall x \in S, P(x, y), \quad (2.29)\]
Section 2.10 Exercises

which, expressed in words, is

There exists some \( y \in T \) such that \( x + y \) is prime for every \( x \in S \).

The statement is false, however, for if \( y = 3 \), then for \( x = 3 \), \( x + y = 6 \) is not prime. Also, for \( y = 4 \), it follows for \( x = 2 \) that \( x + y = 6 \) is not prime. Hence, the quantified statement (2.29) is false.

\[ \Box \]

Suppose that \( Q(x, y) \) is an open sentence, where \( S \) is the domain of \( x \) and \( T \) is the domain of \( y \). The quantified statement

\[ \exists x \in S, \forall y \in T, Q(x, y) \]

is true if \( \forall y \in T, Q(x, y) \) is true for some \( x \in S \). This means that for some element \( x \) in \( S \), the open sentence \( Q(x, y) \) is true for all \( y \in T \).

**Example 2.40** Consider the open sentence

\[ Q(x, y): x + y \text{ is prime}, \]

where the domain of \( x \) is \( S = \{3, 5, 7\} \) and the domain of \( y \) is \( T = \{2, 6, 8, 12\} \). The quantified statement

\[ \exists x \in S, \forall y \in T, Q(x, y), \quad (2.30) \]

expressed in words, is

There exists some \( x \in S \) such that for every \( y \in T \), \( x + y \) is prime.

For \( x = 5 \), all of the numbers \( 5 + 2 \), \( 5 + 6 \), \( 5 + 8 \) and \( 5 + 12 \) are prime. Consequently, the quantified statement (2.30) is true.

\[ \Box \]

Let’s review symbols that we have introduced in this chapter:

\[ \sim \quad \text{negation (not)} \]
\[ \lor \quad \text{disjunction (or)} \]
\[ \land \quad \text{conjunction (and)} \]
\[ \Rightarrow \quad \text{implication} \]
\[ \Leftrightarrow \quad \text{biconditional} \]
\[ \forall \quad \text{universal quantifier (for every)} \]
\[ \exists \quad \text{existential quantifier (there exists)} \]

**SECTION 2.10 EXERCISES**

2.67. Let \( S \) denote the set of odd integers and let

\[ P(x): x^2 + 1 \text{ is even.} \quad \text{and} \quad Q(x): x^2 \text{ is even.} \]

be open sentences over the domain \( S \). State \( \forall x \in S, P(x) \) and \( \exists x \in S, Q(x) \) in words.

2.68. Define an open sentence \( R(x) \) over some domain \( S \) and then state \( \forall x \in S, R(x) \) and \( \exists x \in S, R(x) \) in words.
2.69. State the negations of the following quantified statements, where all sets are subsets of some universal set $U$:

(a) For every set $A$, $A \cap \overline{A} = \emptyset$.

(b) There exists a set $A$ such that $\overline{A} \subseteq A$.

2.70. State the negations of the following quantified statements:

(a) For every rational number $r$, the number $1/r$ is rational.

(b) There exists a rational number $r$ such that $r^2 = 2$.

2.71. Let $P(n) : (5n - 6)/3$ is an integer be an open sentence over the domain $\mathbb{Z}$. Determine, with explanations, whether the following statements are true:

(a) $\forall n \in \mathbb{Z}, P(n)$.

(b) $\exists n \in \mathbb{Z}, P(n)$.

2.72. Determine the truth value of each of the following statements.

(a) $\exists x \in \mathbb{R}, x^2 - x = 0$.

(b) $\forall n \in \mathbb{N}, n + 1 \geq 2$.

(c) $\forall x \in \mathbb{R}, \sqrt{x^2} = x$.

(d) $\exists x \in \mathbb{Q}, 3x^2 - 27 = 0$.

(e) $\exists x \in \mathbb{R}, \exists y \in \mathbb{R}, x + y + 3 = 8$.

(f) $\forall x, y \in \mathbb{R}, x^2 + y^2 = 9$.

(g) $\exists x, y \in \mathbb{R}, x^2 + y^2 = 9$.

(h) $\forall x \in \mathbb{R}, \forall y \in \mathbb{R}, x^2 + y^2 = 9$.

2.73. The statement “For every integer $m$, either $m \leq 1$ or $m^2 \geq 4$.” can be expressed using a quantifier as:

$$\forall m \in \mathbb{Z}, \ m \leq 1 \text{ or } m^2 \geq 4.$$  

Do this for the following two statements.

(a) There exist integers $a$ and $b$ such that both $ab < 0$ and $a + b > 0$.

(b) For all real numbers $x$ and $y$, $x \neq y$ implies that $x^2 + y^2 > 0$.

(c) Express in words the negations of the statements in (a) and (b).

(d) Using quantifiers, express in symbols the negations of the statements in both (a) and (b).

2.74. Let $P(x)$ and $Q(x)$ be open sentences where the domain of the variable $x$ is $S$. Which of the following implies that $(\sim P(x)) \Rightarrow Q(x)$ is false for some $x \in S$?

(a) $P(x) \land Q(x)$ is false for all $x \in S$.

(b) $P(x)$ is true for all $x \in S$.

(c) $Q(x)$ is true for all $x \in S$.

(d) $P(x) \lor Q(x)$ is false for some $x \in S$.

(e) $P(x) \land (\sim Q(x))$ is false for all $x \in S$.

(f) $(\sim P(x)) \land (\sim Q(x))$ is false for all $x \in S$.

2.75. Let $P(x)$ and $Q(x)$ be open sentences where the domain of the variable $x$ is $T$. Which of the following implies that $P(x) \Rightarrow Q(x)$ is true for all $x \in T$?

(a) $P(x) \land Q(x)$ is false for all $x \in T$.

(b) $Q(x)$ is true for all $x \in T$.

(c) $P(x)$ is false for all $x \in T$.

(d) $P(x) \lor (\sim Q(x))$ is true for some $x \in T$.

(e) $P(x)$ is true for all $x \in T$.

(f) $(\sim P(x)) \land (\sim Q(x))$ is false for all $x \in T$.

2.76. Consider the open sentence

$$P(x, y, z): (x - 1)^2 + (y - 2)^2 + (z - 2)^2 > 0.$$
where the domain of each of the variables \( x, y \) and \( z \) is \( \mathbb{R} \).

(a) Express the quantified statement \( \forall x \in \mathbb{R}, \forall y \in \mathbb{R}, \forall z \in \mathbb{R}, P(x, y, z) \) in words.

(b) Is the quantified statement in (a) true or false? Explain.

(c) Express the negation of the quantified statement in (a) in symbols.

(d) Express the negation of the quantified statement in (a) in words.

(e) Is the negation of the quantified statement in (a) true or false? Explain.

2.77. Consider the quantified statement

For every \( s \in S \) and \( t \in S \), \( st - 2 \) is prime.

where the domain of the variables \( s \) and \( t \) is \( S = \{3, 5, 11\} \).

(a) Express this quantified statement in symbols.

(b) Is the quantified statement in (a) true or false? Explain.

(c) Express the negation of the quantified statement in (a) in symbols.

(d) Express the negation of the quantified statement in (a) in words.

(e) Is the negation of the quantified statement in (a) true or false? Explain.

2.78. Let \( A \) be the set of circles in the plane with center \((0, 0)\) and let \( B \) be the set of circles in the plane with center \((1, 1)\). Furthermore, let

\[
P(C_1, C_2): \text{ } C_1 \text{ and } C_2 \text{ have exactly two points in common.}
\]

be an open sentence where the domain of \( C_1 \) is \( A \) and the domain of \( C_2 \) is \( B \).

(a) Express the following quantified statement in words:

\[
\forall C_1 \in A, \exists C_2 \in B, P(C_1, C_2). \tag{2.31}
\]

(b) Express the negation of the quantified statement in (2.31) in symbols.

(c) Express the negation of the quantified statement in (2.31) in words.

2.79. For a triangle \( T \), let \( r(T) \) denote the ratio of the length of the longest side of \( T \) to the length of the smallest side of \( T \). Let \( A \) denote the set of all triangles and let

\[
P(T_1, T_2): \text{ } r(T_2) \geq r(T_1).
\]

be an open sentence where the domain of both \( T_1 \) and \( T_2 \) is \( A \).

(a) Express the following quantified statement in words:

\[
\exists T_1 \in A, \forall T_2 \in A, P(T_1, T_2). \tag{2.32}
\]

(b) Express the negation of the quantified statement in (2.32) in symbols.

(c) Express the negation of the quantified statement in (2.32) in words.

2.80. Consider the open sentence \( P(a, b): a/b < 1 \). where the domain of \( a \) is \( A = \{2, 3, 5\} \) and the domain of \( b \) is \( B = \{2, 4, 6\} \).

(a) State the quantified statement \( \forall a \in A, \exists b \in B, P(a, b) \) in words.

(b) Show the quantified statement in (a) is true.

2.81. Consider the open sentence \( Q(a, b): a - b < 0 \). where the domain of \( a \) is \( A = \{3, 5, 8\} \) and the domain of \( b \) is \( B = \{3, 6, 10\} \).

(a) State the quantified statement \( \exists b \in B, \forall a \in A, Q(a, b) \) in words.

(b) Show the quantified statement in (a) is true.
Let's return to the biconditional $P \iff Q$. Recall that $P \iff Q$ represents the compound statement $(P \implies Q) \land (Q \implies P)$. Earlier, we described how this compound statement can be expressed as

$$P \text{ if and only if } Q.$$  

Many mathematicians abbreviate the phrase “if and only if” by writing “iff.” Although “iff” is informal and, of course, is not a word, its use is common and you should be familiar with it.

Recall that whenever you see

$$P \text{ if and only if } Q,$$

or

$$P \text{ is necessary and sufficient for } Q,$$

this means

$$\text{If } P \text{ then } Q \text{ and if } Q \text{ then } P.$$

Example 2.41 Suppose that

$$P(x) : x = -3 \text{ and } Q(x) : |x| = 3,$$

where $x \in \mathbb{R}$. Then the biconditional $P(x) \iff Q(x)$ can be expressed as

$$x = -3 \text{ if and only if } |x| = 3.$$  

or

$$x = -3 \text{ is necessary and sufficient for } |x| = 3.$$

or, perhaps better, as

$$x = -3 \text{ is a necessary and sufficient condition for } |x| = 3.$$

Let's now consider the quantified statement $\forall x \in \mathbb{R}, \ P(x) \iff Q(x)$. This statement is false because $P(3) \iff Q(3)$ is false.

Suppose that some concept (or object) is expressed in an open sentence $P(x)$ over a domain $S$ and $Q(x)$ is another open sentence over the domain $S$ concerning this concept. We say that this concept is characterized by $Q(x)$ if $\forall x \in S, \ P(x) \iff Q(x)$ is a true statement. The statement $\forall x \in S, \ P(x) \iff Q(x)$ is then called a characterization of this concept. For example, irrational numbers are defined as real numbers that are not rational and are characterized as real numbers whose decimal expansions are nonrepeating. This provides a characterization of irrational numbers:

*A real number $r$ is irrational if and only if $r$ has a nonrepeating decimal expansion.*
We saw that equilateral triangles are defined as triangles whose sides are equal. They are characterized, however, as triangles whose angles are equal. Therefore, we have the characterization:

*A triangle $T$ is equilateral if and only if $T$ has three equal angles.*

You might think that equilateral triangles are also characterized as those triangles having three equal sides but the associated biconditional:

*A triangle $T$ is equilateral if and only if $T$ has three equal sides.*

is not a characterization of equilateral triangles. Indeed, this is the definition we gave of equilateral triangles. A characterization of a concept then gives an alternative, but equivalent, way of looking at this concept. Characterizations are often valuable in studying concepts or in proving other results. We will see examples of this in future chapters.

We mentioned that the following biconditional, though true, is not a characterization: A triangle $T$ is equilateral if and only if $T$ has three equal sides. Although this is the definition of equilateral triangles, mathematicians rarely use the phrase “if and only if” in a definition since this is what is meant in a definition. That is, a triangle is defined to be equilateral if it has three equal sides. Consequently, a triangle with three equal sides is equilateral but a triangle that does not have three equal sides is not equilateral.

### SECTION 2.11 EXERCISES

2.82. Give a definition of each of the following and then state a characterization of each.

(a) Two lines in the plane are perpendicular.
(b) A rational number.

2.83. Define an integer $n$ to be odd if $n$ is not even. State a characterization of odd integers.

2.84. Define a triangle to be isosceles if it has two equal sides. Which of the following statements are characterizations of isosceles triangles? If a statement is not a characterization of isosceles triangles, then explain why.

(a) If a triangle is equilateral, then it is isosceles.
(b) A triangle $T$ is isosceles if and only if $T$ has two equal sides.
(c) If a triangle has two equal sides, then it is isosceles.
(d) A triangle $T$ is isosceles if and only if $T$ is equilateral.
(e) If a triangle has two equal angles, then it is isosceles.
(f) A triangle $T$ is isosceles if and only if $T$ has two equal angles.

2.85. By definition, a right triangle is a triangle one of whose angles is a right angle. Also, two angles in a triangle are complementary if the sum of their degrees is $90^\circ$. Which of the following statements are characterizations of a right triangle? If a statement is not a characterization of a right triangle, then explain why.

(a) A triangle is a right triangle if and only if two of its sides are perpendicular.
(b) A triangle is a right triangle if and only if it has two complementary angles.
(c) A triangle is a right triangle if and only if its area is half of the product of the lengths of some pair of its sides.
Chapter 2 Logic

(d) A triangle is a right triangle if and only if the square of the length of its longest side equals the sum of the squares of the lengths of the two smallest sides.

(e) A triangle is a right triangle if and only if twice of the area of the triangle equals the area of some rectangle.

2.86. Two distinct lines in the plane are defined to be parallel if they don’t intersect. Which of the following is a characterization of parallel lines?

(a) Two distinct lines \( \ell_1 \) and \( \ell_2 \) are parallel if and only if any line \( \ell_3 \) that is perpendicular to \( \ell_1 \) is also perpendicular to \( \ell_2 \).

(b) Two distinct lines \( \ell_1 \) and \( \ell_2 \) are parallel if and only if any line distinct from \( \ell_1 \) and \( \ell_2 \) that doesn’t intersect \( \ell_1 \) also doesn’t intersect \( \ell_2 \).

(c) Two distinct lines \( \ell_1 \) and \( \ell_2 \) are parallel if and only if whenever a line \( \ell \) intersects \( \ell_1 \) in an acute angle \( \alpha \), then \( \ell \) also intersects \( \ell_2 \) in an acute angle \( \alpha \).

(d) Two distinct lines \( \ell_1 \) and \( \ell_2 \) are parallel if and only if whenever a point \( P \) is not on \( \ell_1 \), the point \( P \) is not on \( \ell_2 \).

Chapter 2 Supplemental Exercises

2.87. Construct a truth table for \( P \land (Q \Rightarrow (\sim P)) \).

2.88. Given that the implication \((Q \lor R) \Rightarrow (\sim P)\) is false and \( Q \) is false, determine the truth values of \( R \) and \( P \).

2.89. Find a compound statement involving the component statements \( P \) and \( Q \) that has the truth table given in Figure 2.20.

```
<table>
<thead>
<tr>
<th>P</th>
<th>Q</th>
<th>\sim Q</th>
</tr>
</thead>
<tbody>
<tr>
<td>T</td>
<td>T</td>
<td>F</td>
</tr>
<tr>
<td>T</td>
<td>F</td>
<td>T</td>
</tr>
<tr>
<td>F</td>
<td>T</td>
<td>F</td>
</tr>
<tr>
<td>F</td>
<td>F</td>
<td>T</td>
</tr>
</tbody>
</table>
```

Figure 2.20 Truth table for Exercise 2.89.

2.90. Determine the truth value of each of the following quantified statements:

(a) \( \exists x \in \mathbb{R}, x^3 + 2 = 0 \).
(b) \( \forall n \in \mathbb{N}, 2 \geq 3 - n \).
(c) \( \forall x \in \mathbb{R}, |x| = x \).
(d) \( \exists x \in \mathbb{Q}, x^4 - 4 = 0 \).
(e) \( \exists x, y \in \mathbb{R}, x + y = \pi \).
(f) \( \forall x, y \in \mathbb{R}, x + y = \sqrt{x^2 + y^2} \).

2.91. Rewrite each of the implications below using (1) only if and (2) sufficient.

(a) If a function \( f \) is differentiable, then \( f \) is continuous.
(b) If \( x = -5 \), then \( x^2 = 25 \).

2.92. Let \( P(n); n^2 - n + 5 \) is a prime. be an open sentence over a domain \( S \).

(a) Determine the truth values of the quantified statements \( \forall n \in S, P(n) \) and \( \exists n \in S, \sim P(n) \) for \( S = \{1, 2, 3, 4\} \).
2.101. Let $P(x, y, z)$ be an open sentence, where the domains of $x$, $y$, and $z$ are $A$, $B$, and $C$, respectively.

(a) State the quantified statement $\forall x \in A, \forall y \in B, \exists z \in C, P(x, y, z)$ in words.

(b) State the quantified statement $\forall x \in A, \forall y \in B, \exists z \in C, P(x, y, z)$ in words for $P(x, y, z) : x = yz$.

(c) Determine whether the quantified statement in (b) is true when $A = \{4, 8\}$, $B = \{2, 4\}$ and $C = \{1, 2, 4\}$.

2.101. Let $P(x, y, z)$ be an open sentence, where the domains of $x$, $y$, and $z$ are $A$, $B$, and $C$, respectively.

(a) Express the negation of $\forall x \in A, \forall y \in B, \exists z \in C, P(x, y, z)$ in symbols.

(b) Express $\sim (\forall x \in A, \forall y \in B, \exists z \in C, P(x, y, z))$ in words.
80 Chapter 2 Logic

(c) Determine whether \( \sim (\forall x \in A, \forall y \in B, \exists z \in C, \, P(x, y, z)) \) is true when 
\( P(x, y, z) : x + z = y \) for \( A = \{1, 3\}, \, B = \{3, 5, 7\} \) and \( C = \{0, 2, 4, 6\} \).

2.102. Write each of the following using "if, then."

(a) A sufficient condition for a triangle to be isosceles is that it has two equal angles.
(b) Let \( C \) be a circle of diameter \( \sqrt{2}/\pi \). Then the area of \( C \) is \( 1/2 \).
(c) The 4th power of every odd integer is odd.
(d) Suppose that the slope of a line \( \ell \) is 2. Then the equation of \( \ell \) is \( y = 2x + b \) for some real number \( b \).
(e) Whenever \( a \) and \( b \) are nonzero rational numbers, \( a/b \) is a nonzero rational number.
(f) For every three integers, there exist two of them whose sum is even.
(g) A triangle is a right triangle if the sum of two of its angles is \( 90^\circ \).
(h) The number \( \sqrt{3} \) is irrational.

2.103. State the negation of each of the following statements.

(a) The real number \( r \) has the property that \( 3 \leq r < \pi \).
(b) The real number \( r \) has the property that \( |r - n| \geq \frac{1}{2} \) for every integer \( n \).
(c) The real number \( r \) has the property that \( rs = s \) for every real number \( s \).

2.104. Let \( \{S, T\} \) be a partition of the set \( N \) of positive integers and let \( U \) be a nonempty subset of \( N \). State the negation of each of the following statements.

(a) Every element of \( U \) can be expressed as \( x + y \), where \( x \in S \) and \( y \in T \).
(b) For every \( x \in S \) and \( y \in T \), \( xy \in S \).
(c) For every element \( x \in S \), there is an element \( y \in T \) such that \( y > x \).

2.105. Let \( P(n) \) be an open sentence over the domain \( N \) of positive integers. State the negation of each of the following statements.

(a) If \( P(n) \) is true for infinitely many \( n \in N \), then \( P(n) \) cannot be false for infinitely many \( n \in N \).
(b) There is no element \( n \in N \) such that \( P(n) \) and \( P(n + 1) \) are both true.
(c) If \( P(n) \) is false for some positive integer \( n \), then there is a smallest positive integer \( m \) such that \( P(m) \) is false.

2.106. Each of the following describes an implication. Write the implication in the form "if, then."

(a) For every odd integer \( n \geq 3 \), the integer \( n + m \) is prime for some even integer \( m \).
(b) Let \( n \in N \). The integer \( 2^n \) is even.
(c) We only need to know that \( n \) is odd to show that \( 3n + 4 \) is odd.
(d) Once we know that \( n \) is an even integer, we can conclude that \( n^3 \) is even.
(e) The only possibility for the integer \( n - 3 \) to be even is for \( n \) to be odd.

2.107. Let \( P(n) : 2^n + 1 \) is even. and \( Q(n) : 3^n + 2 \) is odd. be open sentences over the domain \( S = \{0, 1, 2\} \). For which \( n \in S \) is \( P(n) \Rightarrow Q(n) \) true?
3

Direct Proof and Proof by Contrapositive

We are now prepared to begin discussing our main topic: mathematical proofs. Initially, we will be primarily concerned with one question: For a given true mathematical statement, how can we show that it is true? In this chapter you will be introduced to two important proof techniques.

A true mathematical statement whose truth is accepted without proof is referred to as an **axiom**. For example, an axiom of Euclid in geometry states that for every line $\ell$ and point $P$ not on $\ell$, there is a unique line containing $P$ that is parallel to $\ell$. A true mathematical statement whose truth can be verified is often referred to as a **theorem**, although many mathematicians reserve the word “theorem” for such statements that are especially significant or interesting. For example, the mathematical statement “$2 + 3 = 5$” is true but few, if any, would consider this to be a theorem under this latter interpretation. In addition to the word “theorem,” other common terms for such statements include proposition, result, observation and fact, the choice often depending on the significance of the statement or the degree of difficulty of its proof. We will use the word “theorem” sparingly, however, primarily reserving it for true mathematical statements that will be used to verify other mathematical statements that we will encounter later. Otherwise, we will simply use the word “result.” For the most part then, our results are examples used to illustrate proof techniques and our goal is to prove these results.

A **corollary** is a mathematical result that can be deduced from, and is thereby a consequence of, some earlier result. A **lemma** is a mathematical result that is useful in establishing the truth of some other result. Some people like to think of a lemma as a “helping result.” Indeed, the German word for lemma is “hilfsatz,” whose English translation is “helping theorem.” Ordinarily then, a lemma is not of primary importance itself. Indeed, its very existence is due only to its usefulness in proving another (more interesting) result.

Most theorems (or results) are stated as implications. We now begin our study of proofs of such mathematical statements.
3.1 TRIVIAL AND VACUOUS PROOFS

In nearly all of the implications $P \Rightarrow Q$ that we will encounter, $P$ and $Q$ are open sentences; that is, we will actually be considering $P(x) \Rightarrow Q(x)$ or $P(n) \Rightarrow Q(n)$ or some related implication, depending on which variable is being used. The variables $x$ or $n$ (or some other symbols) are used to represent elements of some set $S$ being discussed, that is, $S$ is the domain of the variable. As we have seen, for each value of a variable from its domain, a statement results. (It is possible, of course, that $P$ and $Q$ are expressed in terms of two or more variables.) Whether $P(x)$ (or $Q(x)$) is true ordinarily depends on which element $x \in S$ we are considering; that is, it is rarely the case that $P(x)$ is true for all $x \in S$ (or that $P(x)$ is false for all $x \in S$). For example, for

$$P(n) : 3n^2 - 4n + 1$$

where $n \in \mathbb{Z}$, $P(1)$ is a true statement while $P(2)$ is a false statement. Likewise, it is seldom the case that $Q(x)$ is true for all $x \in S$ or that $Q(x)$ is false for all $x \in S$.

When the quantified statement $\forall x \in S, P(x) \Rightarrow Q(x)$ is expressed as a result or theorem, we often write such a statement as

For $x \in S$, if $P(x)$ then $Q(x)$.

or as

Let $x \in S$. If $P(x)$, then $Q(x)$.

Thus, (3.1) is true if $P(x) \Rightarrow Q(x)$ is a true statement for each $x \in S$; while (3.1) is false if $P(x) \Rightarrow Q(x)$ is false for at least one element $x \in S$.

For a given element $x \in S$, let's recall (see the truth table in Figure 3.1) the conditions under which $P(x) \Rightarrow Q(x)$ has a particular truth value.

**Figure 3.1** The truth table for the implication $P(x) \Rightarrow Q(x)$ for an element $x$ in its domain

Accordingly, if $Q(x)$ is true for all $x \in S$ or $P(x)$ is false for all $x \in S$, then determining the truth or falseness of (3.1) becomes considerably easier. Indeed, if it can be shown that $Q(x)$ is true for all $x \in S$ (regardless of the truth value of $P(x)$), then, according to the truth table for the implication (shown in Figure 3.1), (3.1) is true. This constitutes a proof of (3.1) and is called a **trivial proof**. Accordingly, the statement

Let $n \in \mathbb{Z}$. If $n^3 > 0$, then 3 is odd.
3.1 Trivial and Vacuous Proofs

is true and a (trivial) proof consists only of observing that 3 is an odd integer. The following provides a more interesting example of a trivial proof.

**Result 3.1** Let \( x \in \mathbb{R} \). If \( x < 0 \), then \( x^2 + 1 > 0 \).

**Proof** Since \( x^2 \geq 0 \) for each real number \( x \), it follows that \( x^2 + 1 > x^2 \geq 0 \).

Hence, \( x^2 + 1 > 0 \).

Consider

\[ P(x) : x < 0 \text{ and } Q(x) : x^2 + 1 > 0 \]

where \( x \in \mathbb{R} \). Then Result 3.1 asserts the truth of: For all \( x \in \mathbb{R} \), \( P(x) \Rightarrow Q(x) \). Since we verified that \( Q(x) \) is true for every \( x \in \mathbb{R} \), it follows that \( P(x) \Rightarrow Q(x) \) is true for all \( x \in \mathbb{R} \) and so Result 3.1 is true. In this case, when considered over the domain \( \mathbb{R} \), \( Q(x) \) is actually a true statement. It is this fact that allowed us to give a trivial proof of Result 3.1.

The proof of Result 3.1 does not depend on \( x < 0 \). Indeed, provided that \( x \in \mathbb{R} \), we could have replaced “\( x < 0 \)” by any hypothesis (including the more satisfying “\( x \in \mathbb{R} \)” and the result would still be true. In fact, this new result has the same proof. To be sure, it is rare indeed when a trivial proof is used to verify an implication; nevertheless, this is an important reminder of the truth table in Figure 3.1.

The symbol \( \blacksquare \) that occurs at the end of the proof of Result 3.1 indicates that the proof is complete. There are definite advantages to using \( \blacksquare \) (or some other symbol) to indicate the conclusion of a proof. First, as you start reading a proof, you can look ahead for this symbol to determine the length of the proof. Also, without this symbol, you may continue to read past the end of the proof, still thinking that you’re reading a proof of the result. When you reach this symbol, you are supposed to be convinced that the result is true. If you are, this is good! Everything happened as planned. On the other hand, if you’re not convinced, then, to you, the writer hasn’t presented a proof. This may not be the writer’s fault, however.

In the past, the most common way to indicate that a proof has concluded was to write Q.E.D., which stands for the Latin phrase “quod erat demonstrandum,” whose English translation is “which was to be demonstrated.” Some still use it.

Let \( P(x) \) and \( Q(x) \) be open sentences over a domain \( S \). Then \( \forall x \in S, P(x) \Rightarrow Q(x) \) is a true statement if it can be shown that \( P(x) \) is false for all \( x \in S \) (regardless of the truth value of \( Q(x) \)), according to the truth table for implication. Such a proof is called a vacuous proof of \( \forall x \in S, P(x) \Rightarrow Q(x) \). Therefore,

\[ \text{Let } n \in \mathbb{Z} \text{. If } 3 \text{ is even, then } n^3 > 0. \]

is a true statement. Let’s take a look, however, at a more interesting example of a vacuous proof.

**Result 3.2** Let \( x \in \mathbb{R} \). If \( x^2 - 2x + 2 \leq 0 \), then \( x^3 \geq 8 \).
Chapter 3  Direct Proof and Proof by Contrapositive

Proof  First observe that
\[ x^2 - 2x + 1 = (x - 1)^2 \geq 0. \]
Therefore, \( x^2 - 2x + 2 = (x - 1)^2 + 1 \geq 1 > 0 \). Thus, \( x^2 - 2x + 2 \leq 0 \) is false for all \( x \in \mathbb{R} \) and the implication is true.

For
\[ P(x) : x^2 - 2x + 2 \leq 0 \quad \text{and} \quad Q(x) : x^3 \geq 8 \]
over the domain \( \mathbb{R} \), Result 3.2 asserts the truth of \( \forall x \in \mathbb{R}, P(x) \Rightarrow Q(x) \). Since we verified that \( P(x) \) is false for every \( x \in \mathbb{R} \), it follows that \( P(x) \Rightarrow Q(x) \) is true for each \( x \in \mathbb{R} \). Hence, Result 3.2 is true. In this case, \( P(x) \) is a false statement for each \( x \in \mathbb{R} \). This is what permitted us to give a vacuous proof of Result 3.2.

In the proof of Result 3.2, the truth or falseness of \( x^3 \geq 8 \) played no role whatsoever. Indeed, if we replaced \( x^3 \geq 8 \) by \( x^3 \leq 8 \), for example, then neither the truth nor the proof of Result 3.2 would be affected. Whenever there is a vacuous proof of a result, we often say that the result follows vacuously. As we mentioned, a trivial proof is almost never encountered in mathematics; however, the same cannot be said of vacuous proofs, as we will see later.

We consider one additional example.

Result 3.3  Let \( S = \{n \in \mathbb{Z} : n \geq 2\} \) and let \( n \in S \). If \( 2n + \frac{3}{n} < 5 \), then \( 4n^2 + \frac{4}{n} < 25 \).

Proof  First, we observe that if \( n = 2 \), then \( 2n + \frac{3}{n} = 5 \). Of course, \( 5 < 5 \) is false. If \( n \geq 3 \), then \( 2n + \frac{3}{n} > 2n + 2n \geq 6 \). So, when \( n \geq 3 \), \( 2n + \frac{3}{n} < 5 \) is false as well. Thus, \( 2n + \frac{3}{n} < 5 \) is false for all \( n \in S \). Hence, the implication is true.

In two of the examples that we presented to illustrate trivial and vacuous proofs, we used the fact (and assumed it was known) that \( 3 \) is odd. Also, in the proofs of Results 3.1 and 3.2, we used the fact that if \( r \) is any real number, then \( r^2 \geq 0 \). Although you are certainly familiar with this property of real numbers, it is essential that any facts used within a proof are known to and likely to be recalled by the reader. Facts used within a proof should not come as a surprise to the reader. This subject will be discussed in more detail shortly.

Even though the trivial and vacuous proofs are rarely encountered in mathematics, they are important reminders of the truth table for implication. We are now prepared to introduce the first major proof technique in mathematics.

SECTION 3.1 EXERCISES

3.1. Let \( x \in \mathbb{R} \). Prove that if \( 0 < x < 1 \), then \( x^2 - 2x + 2 \neq 0 \).
3.2. Let \( n \in \mathbb{N} \). Prove that if \( |n - 1| + |n + 1| \leq 1 \), then \( |n^2 - 1| \leq 4 \).
3.3. Let \( r \in \mathbb{Q}^+ \). Prove that if \( \frac{r^2 + 1}{r} \leq 1 \), then \( \frac{r^2 + 2}{r} \leq 2 \).
3.4. Let \( x \in \mathbb{R} \). Prove that if \( x^3 - 5x - 1 \geq 0 \), then \( (x - 1)(x - 3) \geq -2 \).
3.2 Direct Proofs

Typically, when we are discussing an implication \( P(x) \Rightarrow Q(x) \) over a domain \( S \), there is some connection between \( P(x) \) and \( Q(x) \). That is, the truth value of \( Q(x) \) for a particular \( x \in S \) often depends on the truth value of \( P(x) \) for that same element \( x \), or the truth value of \( P(x) \) depends on the truth value of \( Q(x) \). These are the kinds of implications in which we are primarily interested and it is the proofs of these types of results that will occupy much of our attention. We begin with the first major proof technique, which occurs more often in mathematics than any other technique.

Let \( P(x) \) and \( Q(x) \) be open sentences over a domain \( S \). Suppose that our goal is to show that \( P(x) \Rightarrow Q(x) \) is true for every \( x \in S \), that is, our goal is to show that the quantified statement \( \forall x \in S, P(x) \Rightarrow Q(x) \) is true. If \( P(x) \) is false for some \( x \in S \), then \( P(x) \Rightarrow Q(x) \) is true for this element \( x \). Hence, we need only be concerned with showing that \( P(x) \Rightarrow Q(x) \) is true for all \( x \in S \) for which \( P(x) \) is true. In a direct proof of \( P(x) \Rightarrow Q(x) \) for all \( x \in S \), we consider an arbitrary element \( x \in S \) for which \( P(x) \) is true and show that \( Q(x) \) must be true for this element \( x \).

In order to illustrate this type of proof (and others as well), we need to deal with mathematical topics with which we’re all familiar. Let’s first consider the integers and some of their elementary properties. We assume that you are familiar with the integers and the following properties of integers:

1. The negative of every integer is an integer.
2. The sum (and difference) of every two integers is an integer.
3. The product of every two integers is an integer.

We will agree that we can use any of these properties. No justification is required or expected. Initially, we will use even and odd integers to illustrate our proof techniques. In this case, however, any properties of even and odd integers must be verified before they can be used. For example, you probably know that the sum of every two even integers is even but this must first be proved to be used. We need to lay some groundwork before any examples of direct proofs are given.

Since we will be working with even and odd integers, it is essential that we have precise definitions of these kinds of numbers. An integer \( n \) is defined to be even if \( n = 2k \) for some integer \( k \). For example, 10 is even since \( 10 = 2 \cdot 5 \) (where, of course, 5 is an integer). Also, \(-14 = 2(-7)\) is even, as is \( 0 = 2 \cdot 0 \). The integer 17 is not even since there is no integer \( k \) for which \( 17 = 2k \). Thus, we see that the set of all even integers is the set

\[
S = \{2k : k \in \mathbb{Z}\} = \{\ldots, -4, -2, 0, 2, 4, \ldots\}.
\]
86 Chapter 3 Direct Proof and Proof by Contrapositive

We could define an integer \( n \) to be odd if it’s not even but it would be difficult to work with this definition. Instead, we define an integer \( n \) to be odd if \( n = 2k + 1 \) for some integer \( k \). Now 17 is odd since \( 17 = 2 \cdot 8 + 1 \). Also, \(-5\) is odd because \(-5 = 2(-3) + 1\). On the other hand, 26 is not odd since there is no integer \( k \) such that \( 26 = 2k + 1 \). In fact, 26 is even. Hence, according to the definition of odd integers that we have just given, we see that the set of all odd integers is precisely the set

\[
T = \{2k + 1 : k \in \mathbb{Z}\} = \{\ldots, -5, -3, -1, 1, 3, 5, \ldots\}.
\]

Observe that \( S \) and \( T \) are disjoint sets and \( S \cup T = \mathbb{Z} \); that is, \( \mathbb{Z} \) is partitioned into \( S \) and \( T \). Therefore, every integer is either even or odd.

From time to time, we will find ourselves in a position where we have a result to prove and it may not be entirely clear how to proceed. In such a case, we need to consider our options and develop a plan, which we refer to as a proof strategy. The idea is to discuss a proof strategy for the result and, from it, construct a proof. At other times, we may wish to reflect on a proof that we have just given in order to understand it better. Such a discussion will be referred to as a proof analysis. As with examples, we conclude both a proof strategy and a proof analysis with the symbol ♦.

We are now prepared to illustrate the direct proof technique. We follow the proof by a proof analysis.

**Result 3.4** If \( n \) is an odd integer, then \( 3n + 7 \) is an even integer.

**Proof** Assume that \( n \) is an odd integer. Since \( n \) is odd, we can write \( n = 2k + 1 \) for some integer \( k \). Now,

\[
3n + 7 = 3(2k + 1) + 7 = 6k + 3 + 7 = 6k + 10 = 2(3k + 5).
\]

Since \( 3k + 5 \) is an integer, \( 3n + 7 \) is even. ♦

**PROOF ANALYSIS** First, notice that Result 3.4 could have been stated as either

For every odd integer \( n \), the integer \( 3n + 7 \) is even.

or

Let \( n \) be an odd integer. Then \( 3n + 7 \) is even.

Thus, the domain of the variable \( n \) in Result 3.4 is the set of odd integers. In the proof of Result 3.4, the expression \( 2k + 1 \) was substituted for \( n \) in \( 3n + 7 \) and simplified as \( 6k + 10 \). Since our goal was to show that \( 3n + 7 \) is even, we needed to show that \( 3n + 7 \) can be expressed as twice an integer. Consequently, we factored 2 from \( 6k + 10 \) and wrote it as \( 2(3k + 5) \). Since 3 and \( k \) are integers, so is \( 3k \) (the product of two integers is an integer). Since \( 3k \) and 5 are integers, so is \( 3k + 5 \) (the sum of two integers is an integer). Therefore, \( 3n + 7 \) satisfies the definition of an even integer.

One other remark deserves mention here. In the second sentence, we wrote:

Since \( n \) is odd, we can write \( n = 2k + 1 \) for some integer \( k \).

It would be incorrect to write: “If \( n \) is odd” rather than “Since \( n \) is odd” because we have already assumed that \( n \) is odd and therefore \( n \) is now known to be odd. ♦
We defined an integer \( n \) to be odd if we can write \( n = 2k + 1 \) for some integer \( k \). This means that whenever we want to show that an integer, say \( m \), is odd, we must follow this definition; that is, we must show that \( m = 2k + 1 \) for some integer \( k \). (Of course, the use of the symbol \( k \) is not important. For example, an odd integer \( n \) can be written as \( n = 2\ell + 1 \) for some integer \( \ell \).) We could have defined an integer \( n \) to be odd if it is possible to write \( n = 2k - 1 \) for some integer \( k \), but we didn’t. However, if we could prove that an integer \( n \) is odd if and only if \( n \) can be expressed as \( 2k - 1 \) for some integer \( k \), then we could use this characterization of odd integers to show that an integer is odd. This, however, would require additional work on our part with no obvious benefit.

Similarly, we could have defined an integer \( n \) to be even if we can write \( n = 2k + 2 \), or \( n = 2k - 2 \) or perhaps \( n = 2k + 100 \) for some integer \( k \). The definitions of even and odd integers that we chose are probably the most commonly used. Any other definitions that could have been given provide no special advantage to us.

The proof given of Result 3.4 is an example of a direct proof. Let \( Q(n) \): \( 3n + 7 \) is an even integer.

over the domain of odd integers. We verified Result 3.4 by assuming that \( n \) is an arbitrary odd integer and then showing that \( Q(n) \) is true for this element \( n \). Showing that \( Q(n) \) is true essentially required one step on our part. As we venture further into proofs, we will see that we can’t always establish the truth of the desired conclusion so quickly. It may be necessary to establish the truth of some other mathematical statements along the way that can then be used to establish the truth of \( Q(n) \). We will see examples of this later.

Let’s consider another example. For variety, we use an alternative opening sentence and different symbols in the proof of the following result.

**Result 3.5** If \( n \) is an even integer, then \(-5n - 3\) is an odd integer.

**Proof** Let \( n \) be an even integer. Then \( n = 2x \), where \( x \) is an integer. Therefore,

\[
-5n - 3 = -5(2x) - 3 = -10x - 3 = -10x - 4 + 1 = 2(-5x - 2) + 1.
\]

Since \(-5x - 2\) is an integer, \(-5n - 3\) is an odd integer.  

We now consider another example, which may have a surprise ending.

**Result 3.6** If \( n \) is an odd integer, then \( 4n^3 + 2n - 1 \) is odd.

**Proof** Assume that \( n \) is odd. Then \( n = 2y + 1 \) for some integer \( y \). Therefore,

\[
4n^3 + 2n - 1 = 4(2y + 1)^3 + 2(2y + 1) - 1
= 4(8y^3 + 12y^2 + 6y + 1) + 4y + 2 - 1
= 32y^3 + 48y^2 + 28y + 5
= 2(16y^3 + 24y^2 + 14y + 2) + 1.
\]

Since \( 16y^3 + 24y^2 + 14y + 2 \) is an integer, \( 4n^3 + 2n - 1 \) is odd.

**Proof Analysis** Although the direct proof of Result 3.6 that we gave is correct, this is not the desired proof. Indeed, had we observed that

\[
4n^3 + 2n - 1 = 4n^3 + 2n - 2 + 1 = 2(n^3 + n - 1) + 1
\]
Chapter 3  Direct Proof and Proof by Contrapositive

and that \(2n^3 + n - 1 \in \mathbb{Z}\), we could have concluded immediately that \(4n^3 + 2n - 1\) is odd for every integer \(n\). Hence, a trivial proof of Result 3.6 could be given and, in fact, is preferred. The fact that \(4n^3 + 2n - 1\) is odd does not depend on \(n\) being odd. Indeed, it would be far better to replace the statement of Result 3.6 by

If \(n\) is an integer, then \(4n^3 + 2n - 1\) is odd. ♦

We give an additional example of a somewhat different type.

**Result 3.7**  Let \(S = \{1, 2, 3\}\) and let \(n \in S\). If \(\frac{n(n + 3)}{2}\) is even, then \(\frac{(n + 2)(n - 5)}{2}\) is even.

**Proof**  Let \(n \in S\) such that \(n(n + 3)/2\) is even. Since \(n(n + 3)/2 = 2\) when \(n = 1\), \(n(n + 3)/2 = 5\) when \(n = 2\) and \(n(n + 3)/2 = 9\) when \(n = 3\), it follows that \(n = 1\). When \(n = 1\), \((n + 2)(n - 5)/2 = -6\), which is even. Therefore, the implication is true. □

**PROOF ANALYSIS**  In the proof of Result 3.7, we were only concerned with those elements \(n \in S\) for which \(n(n + 3)/2\) is even. Furthermore, it is not initially clear for which elements \(n\) of \(S\) the integer \(n(n + 3)/2\) is even. Since \(S\) consists only of three elements, this can be determined rather quickly, which is what we did. We saw that only \(n = 1\) has the desired property and this is the only element we needed to consider. ♦

If our goal is to establish the truth of \(P(x) \Rightarrow Q(x)\) for all \(x\) in a domain \(S\) by means of a direct proof, then the proof begins by assuming that \(P(x)\) is true for an arbitrary element \(x \in S\). It is often common in this situation, however, to omit the initial assumption that \(P(x)\) is true for an arbitrary element \(x \in S\). It is then understood that we are giving a direct proof. We illustrate this with a short example.

**Result 3.8**  If \(n\) is an even integer, then \(3n^5\) is an even integer.

**Proof**  Since \(n\) is an even integer, \(n = 2x\) for some integer \(x\). Therefore,

\[
3n^5 = 3(2x)^5 = 3(32x^5) = 96x^5 = 2(48x^5).
\]

Since \(48x^5 \in \mathbb{Z}\), the integer \(3n^5\) is even. □

For the present, when giving a direct proof of \(P(x) \Rightarrow Q(x)\) for all \(x\) in a domain \(S\), we will often include the initial assumption that \(P(x)\) is true for an arbitrary element \(x \in S\) in order to solidify this technique in your mind.

**SECTION 3.2 EXERCISES**

3.8. Prove that if \(x\) is an odd integer, then \(9x + 5\) is even.

3.9. Prove that if \(x\) is an even integer, then \(5x - 3\) is an odd integer.

3.10. Prove that if \(a\) and \(c\) are odd integers, then \(ab + bc\) is even for every integer \(b\).

3.11. Let \(n \in \mathbb{Z}\). Prove that if \(1 - n^2 > 0\), then \(3n - 2\) is an even integer.
3.12. Let \( x \in \mathbb{Z} \). Prove that if \( 2^{2x} \) is an odd integer, then \( 2^{-2x} \) is an odd integer.

3.13. Let \( S = \{0, 1, 2\} \) and let \( n \in S \). Prove that if \( (n + 1)^2(n + 2)^2/4 \) is even, then \( (n + 2)^2(n + 3)^2/4 \) is even.

3.14. Let \( S = \{1, 5, 9\} \). Prove that if \( n \in S \) and \( \frac{n^2 + n - 6}{2} \) is odd, then \( \frac{2n^2 + 3n + 6}{6} \) is even.

3.15. Let \( A = \{n \in \mathbb{Z} : n > 2 \text{ and } n \text{ is odd}\} \) and \( B = \{n \in \mathbb{Z} : n < 11\} \). Prove that if \( n \in A \cap B \), then \( n^2 - 2 \) is prime.

### 3.3 Proof by Contrapositive

For statements \( P \) and \( Q \), the **contrapositive** of the implication \( P \Rightarrow Q \) is the implication \((\sim Q) \Rightarrow (\sim P)\). For example, for \( P_1 : 3 \text{ is odd} \) and \( P_2 : 57 \text{ is prime} \), the contrapositive of the implication

\[
P_1 \Rightarrow P_2: \text{If } 3 \text{ is odd, then } 57 \text{ is prime.}
\]

is the implication

\[
(\sim P_2) \Rightarrow (\sim P_1): \text{If } 57 \text{ is not prime, then } 3 \text{ is even.}
\]

The most important feature of the contrapositive \((\sim Q) \Rightarrow (\sim P)\) is that it is logically equivalent to \( P \Rightarrow Q \). This fact is stated formally as a theorem and is verified in the truth table shown in Figure 3.2.

**Theorem 3.9** For every two statements \( P \) and \( Q \), the implication \( P \Rightarrow Q \) and its contrapositive are logically equivalent; that is,

\[
P \Rightarrow Q \equiv (\sim Q) \Rightarrow (\sim P).
\]

**Figure 3.2** The logical equivalence of an implication and its contrapositive

Let

\[
P(x) : x = 2 \text{ and } Q(x) : x^2 = 4
\]

where \( x \in \mathbb{R} \). The contrapositive of the implication

\[
P(x) \Rightarrow Q(x) : \text{If } x = 2, \text{ then } x^2 = 4.
\]

is the implication

\[
(\sim Q(x)) \Rightarrow (\sim P(x)) : \text{If } x^2 \neq 4, \text{ then } x \neq 2.
\]
90 Chapter 3 Direct Proof and Proof by Contrapositive

Suppose that we wish to prove a result (or theorem) that is expressed as

\[ x \in S, \text{ if } P(x), \text{ then } Q(x). \] (3.2)

or as

\[ \text{ For all } x \in S, \text{ if } P(x), \text{ then } Q(x). \] (3.3)

We have seen that a proof of such a result consists of establishing the truth of the implication \( P(x) \Rightarrow Q(x) \) for all \( x \in S \). If it can be shown that \( \sim Q(x) \Rightarrow \sim P(x) \) is true for all \( x \in S \), then \( P(x) \Rightarrow Q(x) \) is true for all \( x \in S \). A proof by contrapositive of the result (3.2) (or of (3.3)) is a direct proof of its contrapositive:

\[ x \in S, \text{ if } \sim Q(x), \text{ then } \sim P(x). \]

or

\[ \text{ For all } x \in S, \text{ if } \sim Q(x), \text{ then } \sim P(x). \]

Thus, to give a proof by contrapositive of (3.2) (or of (3.3)), we assume that \( \sim Q(x) \) is true for an arbitrary element \( x \in S \) and show that \( \sim P(x) \) is true for this element \( x \).

There are certain types of results where a proof by contrapositive is preferable or perhaps even essential. We now give some examples to illustrate this method of proof.

**Result 3.10** Let \( x \in \mathbb{Z} \). If \( 5x - 7 \) is even, then \( x \) is odd.

**Proof** Assume that \( x \) is even. Then \( x = 2a \) for some integer \( a \). So

\[ 5x - 7 = 5(2a) - 7 = 10a - 7 = 10a - 8 + 1 = 2(5a - 4) + 1. \]

Since \( 5a - 4 \in \mathbb{Z} \), the integer \( 5x - 7 \) is odd.

**Proof Analysis** Some comments are now in order. The goal of Result 3.10 was to prove \( P(x) \Rightarrow Q(x) \) for all \( x \in \mathbb{Z} \), where \( P(x) \): \( 5x - 7 \) is even and \( Q(x) \): \( x \) is odd. Since we chose to give a proof by contrapositive, we gave a direct proof of \( \sim Q(x) \Rightarrow \sim P(x) \) for all \( x \in \mathbb{Z} \). Hence, the proof began by assuming that \( x \) is not odd, that is, \( x \) is even. The object then was to show that \( 5x - 7 \) is odd.

Had we attempted to prove Result 3.10 with a direct proof, we would have begun by assuming that \( 5x - 7 \) is even for an arbitrary integer \( x \). Then \( 5x - 7 = 2a \) for some integer \( a \). So, \( x = (2a + 7)/5 \). We then would want to show that \( x \) is odd. With the expression we have for \( x \), it is not even clear that \( x \) is an integer, much less that \( x \) is an odd integer, although, of course, we were told in the statement of Result 3.10 that the domain of \( x \) is the set of integers. Therefore, it is not only that a proof by contrapositive provides us with a rather simple method of proving Result 3.10, but that it may not be immediately clear how or whether a direct proof can be used.

How did we know beforehand that it is a proof by contrapositive that we should use here? This is not as difficult as it may appear. If we use a direct proof, then we begin by assuming that \( 5x - 7 \) is even for an arbitrary integer \( x \); while if we use a proof by contrapositive, then we begin by assuming that \( x \) is even. Therefore, using a proof by contrapositive allows us to work with \( x \) initially rather than the more complicated expression \( 5x - 7 \).
In all of the examples that we have seen so far, we have considered only implications. Now we look at a biconditional.

**Result 3.11** Let \( x \in \mathbb{Z} \). Then \( 11x - 7 \) is even if and only if \( x \) is odd.

**Proof** There are two implications to prove here, namely,

1. if \( x \) is odd, then \( 11x - 7 \) is even and
2. if \( 11x - 7 \) is even, then \( x \) is odd.

We begin with (1). In this case, a direct proof is appropriate. Assume that \( x \) is odd. Then \( x = 2r + 1 \), where \( r \in \mathbb{Z} \). So

\[
11x - 7 = 11(2r + 1) - 7 = 22r + 11 - 7 = 22r + 4 = 2(11r + 2).
\]

Since \( 11r + 2 \) is an integer, \( 11x - 7 \) is even.

We now prove (2), which is the converse of (1). We use a proof by contrapositive here. Assume that \( x \) is even. Then \( x = 2s \), where \( s \in \mathbb{Z} \). Therefore,

\[
11x - 7 = 11(2s) - 7 = 22s - 7 = 22s - 8 + 1 = 2(11s - 4) + 1.
\]

Since \( 11s - 4 \) is an integer, \( 11x - 7 \) is odd.

A comment concerning the statements of Results 3.10 and 3.11 bears repeating here. These results begin with the sentence: Let \( x \in \mathbb{Z} \). This, of course, is informing us that the domain in this case is \( \mathbb{Z} \). That is, we are being told that \( x \) represents an integer. We need not state this assumption in the proof. The sentence “Let \( x \in \mathbb{Z} \)” is commonly called an “overriding” assumption or hypothesis and so \( x \) is assumed to be an integer throughout the proofs of Results 3.10 and 3.11.

In the proof of Result 3.11, we discussed our plan of attack. Namely, we stated that there were two implications to prove and we specifically stated each. Ordinarily we don’t include such information within the proof – unless the proof is quite long, in which case a roadmap indicating the steps we plan to take may be helpful. We give an additional example of this type, where this time a more conventional condensed proof is presented. The following example will be useful to us in the future; thus, we refer to it as a theorem.

**Theorem 3.12** Let \( x \in \mathbb{Z} \). Then \( x^2 \) is even if and only if \( x \) is even.

**Proof** Assume that \( x \) is even. Then \( x = 2a \) for some integer \( a \). Therefore,

\[
x^2 = (2a)^2 = 4a^2 = 2(2a^2).
\]

Because \( 2a^2 \in \mathbb{Z} \), the integer \( x^2 \) is even.

For the converse, assume that \( x \) is odd. So, \( x = 2b + 1 \), where \( b \in \mathbb{Z} \). Then

\[
x^2 = (2b + 1)^2 = 4b^2 + 4b + 1 = 2(2b^2 + 2b) + 1.
\]

Since \( 2b^2 + 2b \) is an integer, \( x^2 \) is odd.

Suppose now that you were asked to prove the following result:

Let \( x \in \mathbb{Z} \). Then \( x^2 \) is odd if and only if \( x \) is odd.  

(3.4)
Chapter 3  Direct Proof and Proof by Contrapositive

How would you do this? You might think of proving the implication “If \( x \) is odd, then \( x^2 \) is odd.” by a direct proof and its converse “If \( x^2 \) is odd, then \( x \) is odd.” by a proof by contrapositive, where, of course, the domain of \( x \) is \( \mathbb{Z} \). If we look at what is happening here, we see that we are duplicating the proof of Theorem 3.12. This is no surprise whatsoever. Theorem 3.12 states that if \( x \) is even, then \( x^2 \) is even and if \( x^2 \) is even, then \( x \) is even. The contrapositive of the first implication is “If \( x^2 \) is odd, then \( x \) is odd.” while the contrapositive of the second implication is “If \( x \) is odd, then \( x^2 \) is odd.” In other words, (3.4) simply restates Theorem 3.12 in terms of contrapositives. Thus, (3.4) requires no proof at all. It is essentially a restatement of Theorem 3.12. And speaking of restatements of Theorem 3.12, we need to recognize that this theorem can be restated in other ways. For example, we could restate

\[
\text{If } x \text{ is an even integer, then } x^2 \text{ is even.}
\]

as

\[
\text{The square of every even integer is even.}
\]

Hence, Theorem 3.12 could be stated as:

\[
\text{An integer is even if and only if its square is even.}
\]

It is not only useful to sometimes restate results in different manners for variety, it is important to recognize what a result is saying regardless of the manner in which it may be stated.

At this point, it is convenient to pause and discuss how theorems (or results) can be used and why it is that we may be interested in proving a particular theorem. First, it is only by providing a proof of a theorem that we know for certain that the theorem is true and therefore have the right to call it a theorem. A fundamental reason why mathematicians may want to give a proof of some mathematical statement is that they consider this a challenge — this is what mathematicians do.

This, in fact, brings up a question that many mathematicians consider of greater importance. Where do such statements come from? Of course, the answer is that they come from mathematicians or students. How these people arrive at such questions does not follow any set rule. But this deals with the creative aspect of mathematics. Some people are curious and imaginative. Perhaps while proving some theorem, it is realized that the method of proof used could be applied to prove something even more interesting. (What is interesting, of course, is quite subjective.) More than likely however, a person has observed some relationship that exists in an example being considered that appears to occur in a more general setting. This individual then attempts to show that this is the case by giving a proof. This entire process involves the idea of conjectures (guesses) and trying to show the accuracy of a conjecture. We’ll discuss this at greater length later.

Suppose that we have been successful in proving \( P(x) \Rightarrow Q(x) \) for all \( x \) in some domain \( S \) (by whatever method). We therefore know that for every \( x \in S \) for which the statement \( P(x) \) is true, the statement \( Q(x) \) is true. Also, for any \( x \in S \) for which the statement \( Q(x) \) is false, the statement \( P(x) \) is false. For example, since we know that Result 3.10 is true, if we should ever encounter an integer \( n \) for which \( 5n - 7 \) is even, then we know that \( n \) is odd. Furthermore, if we should encounter an integer \( n \) for which \( n^2 \) is odd, then we can conclude by statement (3.4) or, better yet, by Theorem 3.12, that \( n \) itself must be odd.
It is not only knowing that a particular theorem might be useful to us in the future, it is perhaps that a theorem seems surprising, interesting or even beautiful. (Yes – to mathematicians, and hopefully to you as well, a theorem can be beautiful.)

We next describe a type of result that we have not yet encountered. Consider the following result, which we would like to prove.

**Result to Prove**

Let $x \in \mathbb{Z}$. If $5x - 7$ is odd, then $9x + 2$ is even.

**Proof Strategy**

This result doesn’t seem to fit into the kinds of results we’ve been proving. (This is not unusual. After learning how to prove certain statements, we encounter new statements that require us to . . . think.) If we attempt to give either a direct proof or a proof by contrapositive of this result, we may be headed for difficulties. There is, however, another approach. Even though we must be very careful about what we are assuming, from what we know about even and odd integers, it appears that if $5x - 7$ is odd, then $x$ must be even. In fact, if we knew that whenever $5x - 7$ is odd then $x$ is even, this fact would be extremely helpful. We illustrate this next. Don’t forget that our goal is to prove the following result, which we will refer to as Result 3.14: Let $x \in \mathbb{Z}$. If $5x - 7$ is odd, then $9x + 2$ is even. The (unusual) numbering of this result is because we will first state and prove a lemma (Lemma 3.13) that will aid us in the proof of Result 3.14.

In order to verify the truth of Result 3.14, we first prove the following lemma.

**Lemma 3.13**

Let $x \in \mathbb{Z}$. If $5x - 7$ is odd, then $x$ is even.

**Proof**

Assume that $x$ is odd. Then $x = 2y + 1$, where $y \in \mathbb{Z}$. Therefore,

$$5x - 7 = 5(2y + 1) - 7 = 10y - 2 = 2(5y - 1).$$

Since $5y - 1$ is an integer, $5x - 7$ is even.

We are now prepared to give a proof of Result 3.14.

**Result 3.14**

Let $x \in \mathbb{Z}$. If $5x - 7$ is odd, then $9x + 2$ is even.

**Proof**

Let $5x - 7$ be an odd integer. By Lemma 3.13, the integer $x$ is even. Since $x$ is even, $x = 2z$ for some integer $z$. Thus,

$$9x + 2 = 9(2z) + 2 = 18z + 2 = 2(9z + 1).$$

Because $9z + 1$ is an integer, $9x + 2$ is even.

So, with the aid of Lemma 3.13, we have produced a very uncomplicated (and, hopefully, easy-to-follow) proof of Result 3.14.

The main reason for presenting Result 3.14 was to show how helpful a lemma can be in producing a proof of another result. However, having just said this, we now show how we can prove Result 3.14 without the aid of a lemma, by performing a bit of algebraic manipulation.
Chapter 3  Direct Proof and Proof by Contrapositive

Assume that $5x - 7$ is odd. Then $5x - 7 = 2n + 1$ for some integer $n$. Observe that

\[
9x + 2 = (5x - 7) + (4x + 9) = 2n + 1 + 4x + 9 = 2n + 4x + 10 = 2(n + 2x + 5).
\]

Because $n + 2x + 5$ is an integer, $9x + 2$ is even.

You may prefer one proof of Result 3.14 over the other. Whether you do or not, it is important to know that two different methods can be used. These methods might prove to be useful for future results you encounter. Also, you might think we used a trick to give the second proof of Result 3.14, but, as we will see, if the same “trick” can be used often, then it becomes a technique.

SECTION 3.3 EXERCISES

3.16. Let $x \in \mathbb{Z}$. Prove that if $7x + 5$ is odd, then $x$ is even.

3.17. Let $n \in \mathbb{Z}$. Prove that if $15n$ is even, then $9n$ is even.

3.18. Let $x \in \mathbb{Z}$. Prove that $5x - 11$ is even if and only if $x$ is odd.

3.19. Let $x \in \mathbb{Z}$. Use a lemma to prove that if $7x + 4$ is even, then $3x - 11$ is odd.

3.20. Let $x \in \mathbb{Z}$. Prove that $3x + 1$ is even if and only if $5x - 2$ is odd.

3.21. Let $n \in \mathbb{Z}$. Prove that $(n + 1)^2 - 1$ is even if and only if $n$ is even.

3.22. Let $S = \{2, 3, 4\}$ and let $n \in S$. Use a proof by contrapositive to prove that if $n^2(n - 1)^2/4$ is even, then $n^2(n + 1)^2/4$ is even.

3.23. Let $A = \{0, 1, 2\}$ and $B = \{4, 5, 6\}$ be subsets of $S = \{0, 1, \ldots, 6\}$. Let $n \in S$. Prove that if $\frac{n(n-1)(n-2)}{6}$ is even, then $n \in A \cup B$.

3.24. Let $n \in \mathbb{Z}$. Prove that $2n^2 + n$ is odd if and only if $\cos \frac{\pi n}{2}$ is even.

3.25. Let $\{A, B\}$ be a partition of the set of $S = \{1, 2, \ldots, 7\}$, where $A = \{1, 4, 5\}$ and $B = \{2, 3, 6, 7\}$. Let $n \in S$. Prove that if $\frac{n^2 + 3n - 4}{2}$ is even, then $n \in A$.

3.4 PROOF BY CASES

While attempting to give a proof of a mathematical statement concerning an element $x$ in some set $S$, it is sometimes useful to observe that $x$ possesses one of two or more properties. A common property that $x$ may possess is that of belonging to a particular subset of $S$. If we can verify the truth of the statement for each property that $x$ may have, then we have a proof of the statement. Such a proof is then divided into parts called cases, one case for each property that $x$ may possess or for each subset to which $x$ may belong. This method is called proof by cases. Indeed, it may be useful in a proof by cases to further divide a case into other cases, called subcases.

For example, in a proof of $\forall n \in \mathbb{Z}, R(n)$, it might be convenient to use a proof by cases whose proof is divided into the two cases

Case 1. $n$ is even. and Case 2. $n$ is odd.

Other possible proofs by cases might involve proving $\forall x \in \mathbb{R}, P(x)$ using the cases
3.4 Proof by Cases

Case 1. $x = 0$. Case 2. $x < 0$. and Case 3. $x > 0$.

Also, we might attempt to prove $\forall n \in \mathbb{N}, P(n)$ using the cases

Case 1. $n = 1$. and Case 2. $n \geq 2$.

Furthermore, for $S = \mathbb{Z} - \{0\}$, we might try to prove $\forall x, y \in S, P(x, y)$ by using the cases:

Case 1. $xy > 0$. and Case 2. $xy < 0$.

Case 1 could, in fact, be divided into two subcases

Subcase 1.1. $x > 0$ and $y > 0$. and Subcase 1.2. $x < 0$ and $y < 0$.

while Case 2 could be divided into the two subcases

Subcase 2.1. $x > 0$ and $y < 0$. and Subcase 2.2. $x < 0$ and $y > 0$.

Let’s look at an example of a proof by cases.

Result 3.15 If $n \in \mathbb{Z}$, then $n^2 + 3n + 5$ is an odd integer.

Proof We proceed by cases, according to whether $n$ is even or odd.

Case 1. $n$ is even. Then $n = 2x$ for some $x \in \mathbb{Z}$. So,

$$n^2 + 3n + 5 = (2x)^2 + 3(2x) + 5 = 4x^2 + 6x + 5 = 2(2x^2 + 3x + 2) + 1.$$ 

Since $2x^2 + 3x + 2 \in \mathbb{Z}$, the integer $n^2 + 3n + 5$ is odd.

Case 2. $n$ is odd. Then $n = 2y + 1$, where $y \in \mathbb{Z}$. Thus,

$$n^2 + 3n + 5 = (2y + 1)^2 + 3(2y + 1) + 5 = 4y^2 + 10y + 9 = 2(2y^2 + 5y + 4) + 1.$$ 

Because $2y^2 + 5y + 4 \in \mathbb{Z}$, the integer $n^2 + 3n + 5$ is odd.

Two integers $x$ and $y$ are said to be of the same parity if $x$ and $y$ are both even or both odd. The integers $x$ and $y$ are of opposite parity if one of $x$ and $y$ is even and the other is odd. For example, 5 and 13 are of the same parity, while 8 and 11 are of opposite parity. Because the definition of two integers having the same (or opposite) parity requires the two integers to satisfy one of two properties, any result containing these terms is likely to be proved by cases. The following theorem presents a characterization of two integers that are of the same parity.

Theorem 3.16 Let $x, y \in \mathbb{Z}$. Then $x$ and $y$ are of the same parity if and only if $x + y$ is even.

Proof First, assume that $x$ and $y$ are of the same parity. We consider two cases.

Case 1. $x$ and $y$ are even. Then $x = 2a$ and $y = 2b$ for some integers $a$ and $b$. So, $x + y = 2a + 2b = 2(a + b)$. Since $a + b \in \mathbb{Z}$, the integer $x + y$ is even.

Case 2. $x$ and $y$ are odd. Then $x = 2a + 1$ and $y = 2b + 1$, where $a, b \in \mathbb{Z}$. Therefore,

$$x + y = (2a + 1) + (2b + 1) = 2a + 2b + 2 = 2(a + b + 1).$$

Since $a + b + 1$ is an integer, $x + y$ is even.

For the converse, assume that $x$ and $y$ are of opposite parity. Again, we consider two cases.
Chapter 3  Direct Proof and Proof by Contrapositive

Case 1. \( x \) is even and \( y \) is odd. Then \( x = 2a \) and \( y = 2b + 1 \), where \( a, b \in \mathbb{Z} \). Then

\[
\begin{align*}
  x + y &= 2a + (2b + 1) = 2(a + b) + 1. \\
\end{align*}
\]

Since \( a + b \in \mathbb{Z} \), the integer \( x + y \) is odd.

Case 2. \( x \) is odd and \( y \) is even. The proof is similar to the proof of the preceding case and is therefore omitted.

PROOF ANALYSIS

A comment concerning the proof of Theorem 3.16 is useful here. Although there is always some concern when omitting steps or proofs, it should be clear that it is truly a waste of effort by writer and reader alike to give a proof of the case when \( x \) is odd and \( y \) is even in Theorem 3.16. Indeed, there is an alternative when the converse is considered.

For the converse, assume that \( x \) and \( y \) are of opposite parity. Without loss of generality, assume that \( x \) is even and \( y \) is odd. Then \( x = 2a \) and \( y = 2b + 1 \), where \( a, b \in \mathbb{Z} \). Then

\[
\begin{align*}
  x + y &= 2a + (2b + 1) = 2(a + b) + 1. \\
\end{align*}
\]

Since \( a + b \in \mathbb{Z} \), the integer \( x + y \) is odd.

We used the phrase without loss of generality (some abbreviate this as WOLOG or WLOG) to indicate that the proofs of the two situations are similar, so the proof of only one of these is needed. Sometimes it is rather subjective to say that two situations are similar. We present one additional example to illustrate this.

Theorem to Prove

Let \( a \) and \( b \) be integers. Then \( ab \) is even if and only if \( a \) is even or \( b \) is even.

PROOF STRATEGY

Before we begin a proof of this result (Theorem 3.17 below), let’s see what we will be required to show. We need to prove two implications, namely: (1) If \( a \) is even or \( b \) is even, then \( ab \) is even. and (2) If \( ab \) is even, then \( a \) is even or \( b \) is even. We consider (1) first. A direct proof seems appropriate. Here, we will assume that \( a \) is even or \( b \) is even. We could give a proof by cases: (i) \( a \) is even, (ii) \( b \) is even. On the other hand, since the proofs of these cases will certainly be similar, we could say, without loss of generality, that \( a \) is even. We will see that it is unnecessary to make any assumption about \( b \).

If we were to give a direct proof of (2), then we would begin by assuming that \( ab \) is even, say \( ab = 2k \) for some integer \( k \). But how could we deduce any information about \( a \) and \( b \) individually? Let’s try another approach. If we use a proof by contrapositive, then we would begin by assuming that it is not the case that \( a \) is even or \( b \) is even. This is exactly the situation covered by one of De Morgan’s laws:

\[
\sim (P \lor Q) \text{ is logically equivalent to } (\sim P) \land (\sim Q).
\]

It is important not to forget this. In this case, we have \( P: a \) is even. and \( Q: b \) is even. So, the negation of “\( a \) is even or \( b \) is even” is “\( a \) is odd and \( b \) is odd.”

Let’s now prove this result.

Theorem 3.17  Let \( a \) and \( b \) be integers. Then \( ab \) is even if and only if \( a \) is even or \( b \) is even.
Section 3.4 Exercises

3.26. Prove that if \( n \in \mathbb{Z} \), then \( n^2 - 3n + 9 \) is odd.

3.27. Prove that if \( n \in \mathbb{Z} \), then \( n^3 - n \) is even.

3.28. Let \( x, y \in \mathbb{Z} \). Prove that if \( xy \) is odd, then \( x \) and \( y \) are odd.

3.29. Let \( a, b \in \mathbb{Z} \). Prove that if \( ab \) is odd, then \( a^2 + b^2 \) is even.

3.30. Let \( x, y \in \mathbb{Z} \). Prove that \( x - y \) is even if and only if \( x \) and \( y \) are of the same parity.

3.31. Let \( a, b \in \mathbb{Z} \). Prove that if \( a + b \) and \( ab \) are of the same parity, then \( a \) and \( b \) are even.

3.32. (a) Let \( x \) and \( y \) be integers. Prove that \( (x + y)^2 \) is even if and only if \( x \) and \( y \) are of the same parity.

(b) Restate the result in (a) in terms of odd integers.
3.33. Let \( A = \{1, 2, 3\} \) and \( B = \{2, 3, 4\} \) be subsets of \( S = \{1, 2, 3, 4\} \). Let \( n \in S \). Prove that \( 2n^2 - 5n \) is either (a) positive and even or (b) negative and odd if and only if \( n \notin A \cap B \).

3.34. Let \( A = \{3, 4\} \) be a subset of \( S = \{1, 2, \ldots, 6\} \). Let \( n \in S \). Prove that if \( \frac{2(n+1)^2}{4} \) is even, then \( n \in A \).

3.35. Prove for every nonnegative integer \( n \) that \( 2^n + 6^n \) is an even integer.

3.36. Let \( x, y \in \mathbb{Z} \). Prove that if \( 3x + 4y \) and \( 4x + 5y \) are both even, then \( x \) and \( y \) are both even.

3.37. Let \( x, y, z \in \mathbb{Z} \). Prove that if exactly two of the three integers \( x, y, z \) are even, then \( 3x + 5y + 7z \) is odd.

3.38. Let \( S = \{8, 12, 20, 24\} \). Prove that if \( \{x, y\} \) is a 2-element subset of \( S \), then either \( x + y = 8k \) for some even integer \( k \) or \( x + y = 4\ell \) for some odd integer \( \ell \).

3.39. Let \( A, B \) and \( C \) be sets. Prove that if \( x \notin A \cup B \) and \( x \notin B \cup C \), then \( x \notin A \cup C \).

3.40. A collection of a nonempty subsets of a nonempty set \( S \) is called a cover of \( S \) if every element of \( S \) belongs to at least one of the subsets. (A cover is a partition of \( S \) if every element of \( S \) belongs to exactly one of the subsets.) Consider the following.

**Result**

Let \( a, b \in \mathbb{Z} \). If \( a \) is even or \( b \) is even, then \( ab \) is even.

**Proof**

Assume that \( a \) is even or \( b \) is even. We consider the following cases.

*Case 1.* \( a \) is even. Then \( a = 2k \), where \( k \in \mathbb{Z} \). Thus, \( ab = (2k)b = 2(kb) \). Since \( kb \in \mathbb{Z} \), it follows that \( ab \) is even.

*Case 2.* \( b \) is even. Then \( b = 2\ell \), where \( \ell \in \mathbb{Z} \). Thus, \( ab = a(2\ell) = 2(a\ell) \). Since \( a\ell \in \mathbb{Z} \), it follows that \( ab \) is even.

Since the domain is \( \mathbb{Z} \) for both \( a \) and \( b \), we might think of \( \mathbb{Z} \times \mathbb{Z} \) being the domain of \( (a, b) \). Consider the following subsets of \( \mathbb{Z} \times \mathbb{Z} \):

\[
S_1 = \{(a, b) \in \mathbb{Z} \times \mathbb{Z} : a \text{ and } b \text{ are odd}\}
\]

\[
S_2 = \{(a, b) \in \mathbb{Z} \times \mathbb{Z} : a \text{ is even}\}
\]

\[
S_3 = \{(a, b) \in \mathbb{Z} \times \mathbb{Z} : b \text{ is even}\}.
\]

(a) Why is \( \{S_1, S_2, S_3\} \) a cover of \( \mathbb{Z} \times \mathbb{Z} \) and not a partition of \( \mathbb{Z} \times \mathbb{Z} \)?

(b) Why does the set \( S_1 \) not appear in the proof above?

(c) Give a proof by cases of the result above where the cases are determined by a partition and not a cover.

### 3.5 PROOF EVALUATIONS

We have now stated several results and have given a proof of each result (sometimes preceding a proof by a proof strategy or following the proof with a proof analysis). Let’s reverse this process by giving an example of a proof of a result but not stating the result being proved. We will follow the proof with several options for the statements of the result being proved.

**Example 3.19**

Given below is a proof of a result.

**Proof**

Assume that \( n \) is an odd integer. Then \( n = 2k + 1 \) for some integer \( k \). Then

\[
3n - 5 = 3(2k + 1) - 5 = 6k + 3 - 5 = 6k - 2 = 2(3k - 1).
\]

Since \( 3k - 1 \) is an integer, \( 3n - 5 \) is even.
3.5 Proof Evaluations

Which of the following is proved above?

(1) $3n - 5$ is an even integer.
(2) If $n$ is an odd integer, then $3n - 5$ is an even integer.
(3) Let $n$ be an integer. If $3n - 5$ is an even integer, then $n$ is an odd integer.
(4) Let $n$ be an integer. If $3n - 5$ is an odd integer, then $n$ is an even integer.

The correct answers are (2) and (4). The proof given is a direct proof of (2) and a proof by contrapositive of (4). The sentence (1) is an open sentence, not a statement, and is only the conclusion of (2). Statement (3) is the converse of (2).

When learning any mathematical subject, it is not the least bit unusual to make mistakes along the way. In fact, part of learning mathematics is to learn from your mistakes and those of others. For this reason, you will see a few exercises at the end of several chapters (beginning with this chapter) where you are asked to evaluate the proof of a result. That is, a result and a proposed proof of this result will be given. You are then asked to read this proposed proof and determine whether, in your opinion, it is, in fact, a proof. If you don’t believe that the given argument provides a proof of the result, then you should point out the (or a) mistake. We give two examples of this.

Problem 3.20 Evaluate the proposed proof of the following result.

Result If $x$ and $y$ are integers of the same parity, then $x - y$ is even.

Proof Let $x$ and $y$ be two integers of the same parity. We consider two cases, according to whether $x$ and $y$ are both even or are both odd.

Case 1. $x$ and $y$ are both even. Let $x = 6$ and $y = 2$, which are both even. Then $x - y = 4$, which is even.

Case 2. $x$ and $y$ are both odd. Let $x = 7$ and $y = 1$, which are both odd. Then $x - y = 6$, which is even.

Proof Evaluation Although the proof started correctly, assuming that $x$ and $y$ are two integers of the same parity and dividing the proof into these two cases, the proof of each case is incorrect. When we assume that $x$ and $y$ are both even, for example, $x$ and $y$ must represent arbitrary even integers, not specific even integers.

Problem 3.21 Evaluate the proposed proof of the following result.

Result If $m$ is an even integer and $n$ is an odd integer, then $3m + 5n$ is odd.

Proof Let $m$ be an even integer and $n$ an odd integer. Then $m = 2k$ and $n = 2k + 1$, where $k \in \mathbb{Z}$. Therefore,

$$3m + 5n = 3(2k) + 5(2k + 1) = 6k + 10k + 5 = 16k + 5 = 2(8k + 2) + 1.$$ 

Since $8k + 2$ is an integer, $3m + 5n$ is odd.
100  Chapter 3  Direct Proof and Proof by Contrapositive

**Proof Evaluation** There is a mistake in the second sentence of the proposed proof, where it is written that \( m = 2k \) and \( n = 2k + 1 \), where \( k \in \mathbb{Z} \). Since the same symbol \( k \) is used for both \( m \) and \( n \), we have inadvertently added the assumption that \( n = m + 1 \). This is incorrect, however, as it was never stated that \( m \) and \( n \) must be consecutive integers. In other words, we should write \( m = 2k \) and \( n = 2\ell + 1 \), say, where \( k, \ell \in \mathbb{Z} \).

**SECTION 3.5 EXERCISES**

3.41. Below is a proof of a result.

**Proof** We consider two cases.

*Case 1.* \( a \) and \( b \) are even. Then \( a = 2r \) and \( b = 2s \) for integers \( r \) and \( s \). Thus,

\[
a^2 - b^2 = (2r)^2 - (2s)^2 = 4r^2 - 4s^2 = 2(2r^2 - 2s^2).
\]

Since \( 2r^2 - 2s^2 \) is an integer, \( a^2 - b^2 \) is even.

*Case 2.* \( a \) and \( b \) are odd. Then \( a = 2r + 1 \) and \( b = 2s + 1 \) for integers \( r \) and \( s \). Thus,

\[
a^2 - b^2 = (2r + 1)^2 - (2s + 1)^2 = (4r^2 + 4r + 1) - (4s^2 + 4s + 1)
= 4r^2 + 4r - 4s^2 - 4s = 2(2r^2 + 2r - 2s^2 - 2s).
\]

Since \( 2r^2 + 2r - 2s^2 - 2s \) is an integer, \( a^2 - b^2 \) is even.

Which of the following is proved?

1. Let \( a, b \in \mathbb{Z} \). Then \( a \) and \( b \) are of the same parity if and only if \( a^2 - b^2 \) is even.
2. Let \( a, b \in \mathbb{Z} \). Then \( a^2 - b^2 \) is even.
3. Let \( a, b \in \mathbb{Z} \). If \( a \) and \( b \) are of the same parity, then \( a^2 - b^2 \) is even.
4. Let \( a, b \in \mathbb{Z} \). If \( a^2 - b^2 \) is even, then \( a \) and \( b \) are of the same parity.

3.42. Below is given a proof of a result. Which result is being proved?

**Proof** Assume that \( x \) is even. Then \( x = 2a \) for some integer \( a \). So,

\[
3x^2 - 4x - 5 = 3(2a)^2 - 4(2a) - 5 = 12a^2 - 8a - 5 = 2(6a^2 - 4a - 3) + 1.
\]

Since \( 6a^2 - 4a - 3 \) is an integer, \( 3x^2 - 4x - 5 \) is odd.

For the converse, assume that \( x \) is odd. So, \( x = 2b + 1 \), where \( b \in \mathbb{Z} \). Therefore,

\[
3x^2 - 4x - 5 = 3(2b + 1)^2 - 4(2b + 1) - 5 = 3(4b^2 + 4b + 1) - 8b - 4 - 5
= 12b^2 + 12b - 6 = 2(6b^2 + 2b - 3).
\]

Since \( 6b^2 + 2b - 3 \) is an integer, \( 3x^2 - 4x - 5 \) is even.

3.43. Evaluate the proof of the following result.

**Result** Let \( n \in \mathbb{Z} \). If \( 3n - 8 \) is odd, then \( n \) is odd.

**Proof** Assume that \( n \) is odd. Then \( n = 2k + 1 \) for some integer \( k \). Then \( 3n - 8 = 3(2k + 1) - 8 = 6k + 3 - 8 = 6k - 5 = 2(3k - 3) + 1 \). Since \( 3k - 3 \) is an integer, \( 3n - 8 \) is odd.
3.44. Evaluate the proof of the following result.

**Result** Let \( a, b \in \mathbb{Z} \). Then \( a - b \) is even if and only if \( a \) and \( b \) are of the same parity.

**Proof** We consider two cases.

Case 1. \( a \) and \( b \) are of the same parity. We now consider two subcases.

Subcase 1.1. \( a \) and \( b \) are both even. Then \( a = 2x \) and \( b = 2y \), where \( x, y \in \mathbb{Z} \). Then \( a - b = 2x - 2y = 2(x - y) \). Since \( x - y \) is an integer, \( a - b \) is even.

Subcase 1.2. \( a \) and \( b \) are both odd. Then \( a = 2x + 1 \) and \( b = 2y + 1 \), where \( x, y \in \mathbb{Z} \). Then \( a - b = (2x + 1) - (2y + 1) = 2(x - y) \). Since \( x - y \) is an integer, \( a - b \) is even.

Case 2. \( a \) and \( b \) are of opposite parity. We again have two subcases.

Subcase 2.1. \( a \) is odd and \( b \) is even. Then \( a = 2x + 1 \) and \( b = 2y \), where \( x, y \in \mathbb{Z} \). Then \( a - b = 2x + 1 - 2y = 2(x - y) + 1 \). Since \( x - y \) is an integer, \( a - b \) is odd.

Subcase 2.2. \( a \) is even and \( b \) is odd. Then \( a = 2x \) and \( b = 2y + 1 \), where \( x, y \in \mathbb{Z} \). Then \( a - b = 2x - (2y + 1) = 2x - 2y - 1 = 2(x - y - 1) + 1 \). Since \( x - y - 1 \) is an integer, \( a - b \) is odd.

3.45. The following is an attempted proof of a result. What is the result and is the attempted proof correct?

**Proof** Assume, without loss of generality, that \( x \) is even. Then \( x = 2a \) for some integer \( a \). Thus,

\[
xy = (2a)y^2 = 2(ay^2).
\]

Since \( ay^2 \) is an integer, \( xy^2 \) is even.

3.46. Given below is a proof of a result. What is the result?

**Proof** Assume, without loss of generality, that \( x \) and \( y \) are even. Then \( x = 2a \) and \( y = 2b \) for integers \( a \) and \( b \). Therefore,

\[
xy + xz + yz = (2a)(2b) + (2a)z + (2b)z = 2(2ab + az + bz).
\]

Since \( 2ab + az + bz \) is an integer, \( xy + xz + yz \) is even.

3.47. What result is being proved below and what procedure is being used to verify the result? First, we present the following proof.

**Proof** Assume that \( x \) is even. Then \( x = 2a \) for some integer \( a \). Thus,

\[
7x - 3 = 7(2a) - 3 = 14a - 3 = 14a - 4 + 1 = 2(7a - 2) + 1.
\]

Since \( 7a - 2 \) is an integer, \( 7x - 3 \) is odd.

We are now prepared to prove our main result.

**Proof** Assume that \( 7x - 3 \) is even. From the result above, \( x \) is odd. So, \( x = 2b + 1 \) for some integer \( b \). Thus,

\[
3x + 8 = 3(2b + 1) + 8 = 6b + 11 = 2(3b + 5) + 1.
\]

Since \( 3b + 5 \) is an integer, \( 3x + 8 \) is odd.

3.48. Consider the following statement.

Let \( n \in \mathbb{Z} \). Then \((n - 5)(n + 7)(n + 13)\) is odd if and only if \( n \) is even. Which of the following would be an appropriate way to begin a proof of this statement?

(a) Assume that \((n - 5)(n + 7)(n + 13)\) is odd.
(b) Assume that \((n - 5)(n + 7)(n + 13)\) is even.
(c) Assume that \( n \) is even.
(d) Assume that \( n \) is odd.
(e) We consider two cases, according to whether \( n \) is even or \( n \) is odd.

Chapter 3 Supplemental Exercises

3.49. Let \( x \in \mathbb{Z} \). Prove that if \( 7x - 8 \) is even, then \( x \) is even.

3.50. Let \( x \in \mathbb{Z} \). Prove that \( x^3 \) is even if and only if \( x \) is even.

3.51. Let \( x \in \mathbb{Z} \). Use one or two lemmas to prove that \( 3x^3 \) is even if and only if \( 5x^2 \) is even.

3.52. Give a direct proof of the following: Let \( x \in \mathbb{Z} \). If \( 11x - 5 \) is odd, then \( x \) is even.

3.53. Let \( x, y \in \mathbb{Z} \). Prove that if \( x + y \) is odd, then \( x \) and \( y \) are of opposite parity.

3.54. Let \( x, y \in \mathbb{Z} \). Prove that if \( 3x + 5y \) is even, then \( x \) and \( y \) are of the same parity.

3.55. Let \( x, y \in \mathbb{Z} \). Prove that \( (x + 1)y^2 \) is even if and only if \( x \) is odd or \( y \) is even.

3.56. Let \( x, y \in \mathbb{Z} \). Prove that if \( xy \) and \( x + y \) are even, then both \( x \) and \( y \) are even.

3.57. Prove, for every integer \( x \), that the integers \( 3x + 1 \) and \( 5x + 2 \) are of opposite parity.

3.58. Prove the following two results:
   (a) Result A: Let \( n \in \mathbb{Z} \). If \( n^3 \) is even, then \( n \) is even.
   (b) Result B: If \( n \) is an odd integer, then \( 5n^9 + 13 \) is even.

3.59. Prove for every two distinct real numbers \( a \) and \( b \) that either \( a + b \geq \frac{a+b}{2} \) or \( a + b \leq \frac{a+b}{2} \).

3.60. Let \( x, y \in \mathbb{Z} \). Prove that if \( a \) and \( b \) are even integers, then \( ax + by \) is even.

3.61. Evaluate the proof of the following result.
   **Result** Let \( x, y \in \mathbb{Z} \) and let \( a \) and \( b \) be odd integers. If \( ax + by \) is even, then \( x \) and \( y \) are of the same parity.
   **Proof** Assume that \( x \) and \( y \) are of opposite parity. Then \( x = 2p \) and \( y = 2q + 1 \) for some integers \( p \) and \( q \). Since \( a \) and \( b \) are odd integers, \( a = 2r + 1 \) and \( b = 2s + 1 \) for integers \( r \) and \( s \). Hence,

   \[
   ax + by = (2r + 1)(2p) + (2s + 1)(2q + 1) \\
   = 4pr + 2p + 4qs + 2s + 2q + 1 \\
   = 2(2pr + p + 2qs + s + q) + 1.
   
   Since \( 2pr + p + 2qs + s + q \) is an integer, \( ax + by \) is odd.

3.62. Let \( S = \{a, b, c, d\} \) be a set of four distinct integers. Prove that if either (1) for each \( x \in S \), the integer \( x \) and the sum of any two of the remaining three integers of \( S \) are of the same parity or (2) for each \( x \in S \), the integer \( x \) and the sum of any two of the remaining three integers of \( S \) are of opposite parity, then every pair of integers of \( S \) are of the same parity.

3.63. Prove that if \( a \) and \( b \) are two positive integers, then \( a^2(b + 1) + b^2(a + 1) \geq 4ab \).

3.64. Let \( a, b \in \mathbb{Z} \). Prove that if \( ab = 4 \), then \( (a - b)^3 - 9(a - b) = 0 \).
3.65. Let \(a\), \(b\) and \(c\) be the lengths of the sides of a triangle \(T\) where \(a \leq b \leq c\). Prove that if \(T\) is a right triangle, then
\[
(abc)^2 = \frac{c^6 - a^6 - b^6}{3}.
\]

3.66. Consider the following statement.
Let \(n \in \mathbb{Z}\). Then \(3n^3 + 4n^2 + 5\) is even if and only if \(n\) is even.
Which of the following would be an appropriate way to begin a proof of this statement?
(a) Assume that \(3n^3 + 4n^2 + 5\) is odd.
(b) Assume that \(3n^3 + 4n^2 + 5\) is even.
(c) Assume that \(n\) is even.
(d) Assume that \(n\) is odd.
(e) We consider two cases, according to whether \(n\) is even or \(n\) is odd.

3.67. Let \(P = \{A, B, C\}\) be a partition of a set \(S\) of integers, where \(A = \{n \in S: n\) is odd and \(n > 0\}\), \(B = \{n \in S: n\) is odd and \(n < 0\}\) and \(C = \{n \in S: n\) is even and \(n > 0\}\).
Prove that if \(x\) and \(y\) are elements of \(S\) belonging to distinct subsets in \(P\), then \(xy\) is either odd, even and greater than 1, or even and less than \(-1\).

3.68. Let \(n \in \mathbb{N}\). Prove that if \(n^3 - 5n - 10 > 0\), then \(n \geq 3\).

3.69. Prove for every odd integer \(a\) that \((a^2 + 3)(a^2 + 7) = 32b\) for some integer \(b\).

3.70. Prove for every two positive integers \(a\) and \(b\) that
\[
(a + b) \left( \frac{1}{a} + \frac{1}{b} \right) \geq 4.
\]

3.71. Which result is being proved below and what procedure is being used to verify the result?
We begin with the following proof.

**Proof** First, assume that \(x\) is even. Then \(x = 2a\), where \(a \in \mathbb{Z}\). Thus,
\[
3x - 2 = 3(2a) - 2 = 6a - 2 = 2(3a - 1).
\]
Since \(3a - 1\) is an integer, \(3x - 2\) is even.

Next, suppose that \(x\) is odd. Then \(x = 2b + 1\) for some integer \(b\). So,
\[
3x - 2 = 3(2b + 1) - 2 = 6b + 1 = 2(3b) + 1.
\]
Since \(3b\) is an integer, \(3x - 2\) is odd.

We can now give the following proof.

**Proof** First, assume that \(3x - 2\) is even. From the preceding result, \(x\) is even and so \(x = 2a\), where \(a \in \mathbb{Z}\). Thus,
\[
5x + 1 = 5(2a) + 1 = 2(5a) + 1.
\]
Since \(5a\) is an integer, \(5x + 1\) is odd.

Next, assume that \(3x - 2\) is odd. Again, by the preceding result, \(x\) is odd. Hence, \(x = 2b + 1\) for some integer \(b\). Therefore,
\[
5x + 1 = 5(2b + 1) + 1 = 10b + 6 = 2(5b + 3).
\]
Since \(5b + 3\) is an integer, \(5x + 1\) is even.
104 Chapter 3 Direct Proof and Proof by Contrapositive

3.72. Prove that if $a$ is an odd integer, then $5a^2 - 3a + 5$ is odd.

3.73. Let $x, y \in \mathbb{Z}$. Prove that if $3x + 7y$ is odd or $5x + 6y$ is even, then $x$ or $y$ is even.

3.74. Let $a, b, c \in \mathbb{Z}$. Prove that if $a^2 + b^2 = c^2$, then $abc$ is even.

3.75. Let $S$ be the set of positive odd integers and let $A = \{2a : a \in S\}$, $B = \{4b : b \in S\}$, $C = \{8c : c \in S\}$ and $D = \{16d : d \in S\}$. Prove that if $x, y$ and $z$ are positive integers belonging to distinct sets $A, B, C, D$, then $x + y + z \in A \cup B$. 
4

More on Direct Proof and Proof by Contrapositive

The vast majority of the examples illustrating direct proof and proof by contrapositive that we have seen involve properties of even and odd integers. In this chapter, we will give additional examples of direct proofs and proofs by contrapositive concerning integers but in new surroundings. First, we will see how even and odd integers can be studied in a more general setting, through divisibility of integers. We will then explore some properties of real numbers and, finally, look at some properties of set operations.

4.1 PROOFS INVOLVING DIVISIBILITY OF INTEGERS

We have now seen many examples of integers that can be written as $2x$ for some integer $x$. These are precisely the even integers, of course. However, some integers can also be expressed as $3x$ or $4x$, or as $-5x$ for some integer $x$. In general, for integers $a$ and $b$ with $a \neq 0$, we say that $a$ divides $b$ if there is an integer $c$ such that $b = ac$. In this case, we write $a \mid b$. Hence, if $n$ is an even integer, then $2 \mid n$; moreover, if 2 divides some integer $n$, then $n$ is even. That is, an integer $n$ is even if and only if $2 \mid n$. Theorem 3.17 (which states for integers $a$ and $b$, that $ab$ is even if and only if $a$ or $b$ is even) can therefore be restated for integers $a$ and $b$ as: $2 \mid ab$ if and only if $2 \mid a$ or $2 \mid b$.

If $a \mid b$, then we also say that $b$ is a multiple of $a$ and that $a$ is a divisor of $b$. Thus, every even integer is a multiple of 2. If $a$ does not divide $b$, then we write $a \nmid b$. For example, 4 $\mid 48$ since $48 = 4 \cdot 12$ and $-3 \nmid 57$ since $57 = (-3) \cdot (-19)$. On the other hand, $4 \nmid 66$ as there is no integer $c$ such that $66 = 4c$.

We now apply the techniques we’ve learned to prove some results concerning divisibility properties of integers.

**Result to Prove**

Let $a$, $b$ and $c$ be integers with $a \neq 0$ and $b \neq 0$. If $a \mid b$ and $b \mid c$, then $a \mid c$.

**Proof Strategy**

It seems reasonable here to use a direct proof and to begin by assuming that $a \mid b$ and $b \mid c$. This means that $b = ax$ and $c = by$ for some integers $x$ and $y$. Since our goal is to
show that $a \mid c$, we need to show that $c$ can be written as the product of $a$ and some other integer. Hence, it is logical to consider $c$ and determine how we can express it. ♦

**Result 4.1** Let $a$, $b$ and $c$ be integers with $a \neq 0$ and $b \neq 0$. If $a \mid b$ and $b \mid c$, then $a \mid c$.

**Proof** Assume that $a \mid b$ and $b \mid c$. Then $b = ax$ and $c = by$, where $x, y \in \mathbb{Z}$. Therefore, $c = by = (ax)y = a(xy)$. Since $xy$ is an integer, $a \mid c$.

We now verify two other divisibility properties of integers.

**Result 4.2** Let $a$, $b$, $c$ and $d$ be integers with $a \neq 0$ and $b \neq 0$. If $a \mid c$ and $b \mid d$, then $ab \mid cd$.

**Proof** Let $a \mid c$ and $b \mid d$. Then $c = ax$ and $d = by$, where $x, y \in \mathbb{Z}$. Then $cd = (ax)(by) = (ab)(xy)$. Since $xy$ is an integer, $ab \mid cd$.

**Result 4.3** Let $a$, $b$, $c$, $x$, $y \in \mathbb{Z}$, where $a \neq 0$. If $a \mid b$ and $a \mid c$, then $a \mid (bx + cy)$.

**Proof** Assume that $a \mid b$ and $a \mid c$. Then $b = ar$ and $c = as$, where $r, s \in \mathbb{Z}$. Then $bx + cy = (ar)x + (as)y = a(rx + sy)$. Since $rx + sy$ is an integer, $a \mid (bx + cy)$.

The examples that we have presented thus far concern general properties of divisibility of integers. We now look at some specialized properties of divisibility.

**Result 4.4** Let $x \in \mathbb{Z}$. If $2 \mid (x^2 - 1)$, then $4 \mid (x^2 - 1)$.

**Proof** Assume that $2 \mid (x^2 - 1)$. So $x^2 - 1 = 2y$ for some integer $y$. Thus, $x^2 = 2y + 1$ is an odd integer. It then follows by Theorem 3.12 that $x$ too is odd. Hence, $x = 2z + 1$ for some integer $z$. Then $x^2 - 1 = (2z + 1)^2 - 1 = (4z^2 + 4z + 1) - 1 = 4z^2 + 4z = 4(z^2 + z)$. Since $z^2 + z$ is an integer, $4 \mid (x^2 - 1)$.

For each of the Results 4.1–4.4, a direct proof worked very well. For the following result, however, the situation is quite different.

**Result to Prove** Let $n \in \mathbb{Z}$. If $5 \nmid (n^2 + 4)$, then $5 \nmid (n - 1)$ and $5 \nmid (n + 1)$.

**Proof Strategy** If we let

$$ P: 5 \nmid (n^2 + 4), \quad Q: 5 \nmid (n - 1) \quad \text{and} \quad R: 5 \nmid (n + 1), $$

then we wish to prove that $P \Rightarrow Q \land R$ for every integer $n$. (It should be clear that $P$, $Q$ and $R$ are open sentences in this case, but we omit the variable $n$ here for simplicity.) If we use a direct proof, then we would assume that $5 \nmid (n^2 + 4)$ and attempt to show that
5 \mid (n - 1) \text{ and } 5 \mid (n + 1). \text{ Thus, we would then know that } n^2 + 4 \text{ cannot be expressed as 5 times an integer. On the other hand, if we use a proof by contrapositive, then we are considering the implication } (\sim (Q \land R)) \Rightarrow (\sim P), \text{ which, by De Morgan's Law, is logically equivalent to } ((\sim Q) \lor (\sim R)) \Rightarrow (\sim P) \text{ and which, in words, is: If } 5 \mid (n - 1) \text{ or } 5 \mid (n + 1), \text{ then } 5 \mid (n^2 + 4). \text{ This method looks more promising.}

\textbf{Result 4.5} \quad \text{Let } n \in \mathbb{Z}. \text{ If } 5 \mid (n^2 + 4), \text{ then } 5 \mid (n - 1) \text{ and } 5 \mid (n + 1).

\textbf{Proof} \quad \text{Assume that } 5 \mid (n - 1) \text{ or } 5 \mid (n + 1). \text{ We consider these two cases.}

\textbf{Case 1.} \quad 5 \mid (n - 1). \text{ Then } n - 1 = 5a \text{ for some integer } a. \text{ So, } n = 5a + 1. \text{ Hence,}

\[ n^2 + 4 = (5a + 1)^2 + 4 = (25a^2 + 10a + 1) + 4 = 5(5a^2 + 2a + 1). \]

\text{Since } 5a^2 + 2a + 1 \in \mathbb{Z}, \text{ it follows that } 5 \mid (n^2 + 4).

\textbf{Case 2.} \quad 5 \mid (n + 1). \text{ Then } n + 1 = 5b, \text{ where } b \in \mathbb{Z}, \text{ and so } n = 5b - 1. \text{ Hence,}

\[ n^2 + 4 = (5b - 1)^2 + 4 = (25b^2 - 10b + 1) + 4 = 5(5b^2 - 2b + 1). \]

\text{Since } 5b^2 - 2b + 1 \in \mathbb{Z}, \text{ it follows that } 5 \mid (n^2 + 4). \square

We have already mentioned that if an integer } n \text{ is not a multiple of 2, then we can write } n = 2q + 1 \text{ for some integer } q \text{ (that is, if an integer } n \text{ is not even, then it is odd). This is a consequence of knowing that 0 and 1 are the only possible remainders when an integer is divided by 2. Along the same lines, if an integer } n \text{ is not a multiple of 3, then we can write } n = 3q + 1 \text{ or } n = 3q + 2 \text{ for some integer } q, \text{ that is,}

\quad \text{every integer can be expressed as } 3q, 3q + 1 \text{ or } 3q + 2

\text{for some integer } q \text{ since 0, 1 and 2 are the only remainders that can result when an integer is divided by 3. Similarly,}

\quad \text{every integer can be expressed as } 4q, 4q + 1, 4q + 2 \text{ or } 4q + 3

\text{for some integer } q. \text{ This topic concerns a well-known theorem called the Division Algorithm, which will be explored in more detail in Chapter 12.}

\text{We now consider a result that makes use of these facts.}

\textbf{Result to Prove} \quad \text{Let } x \in \mathbb{Z}.

\textbf{(a)} \quad \text{If } 3 \mid x, \text{ then } 3 \mid x^2; \text{ while if } 3 \nmid x, \text{ then } 3 \mid (x^2 - 1).

\textbf{(b)} \quad \text{If } x \text{ is even, then } 4 \mid x^2; \text{ while if } x \text{ is odd, then } 8 \mid (x^2 - 1) \text{ and so } 4 \mid (x^2 - 1).

\textbf{Proof Strategy} \quad \text{For (a), if } 3 \mid x, \text{ then } x = 3q \text{ for some integer } q. \text{ If, on the other hand, } 3 \nmid x, \text{ then either } x = 3q + 1 \text{ or } x = 3q + 2 \text{ for some integer } q. \text{ A direct proof should proceed as expected in each case. For (b), if } x \text{ is even, then } x = 2q \text{ for some integer } q \text{ and it should be quite routine to show that } 4 \mid x^2. \text{ If } x \text{ is odd, however, then writing } x = 2q + 1 \text{ for some integer } q \text{ does not lead to the desired conclusion that } 8 \mid (x^2 - 1). \text{ We have seen that every integer can be written as } 4q, 4q + 1, 4q + 2 \text{ or } 4q + 3 \text{ for some integer } q. \text{ Since } x \text{ is odd, either } x = 4q + 1 \text{ or } x = 4q + 3. \text{ Making this observation is helpful.} \diamond
More on Direct Proof and Proof by Contrapositive

Result 4.6  Let \( x \in \mathbb{Z} \).

(a) If \( 3 \mid x \), then \( 3 \mid x^2 \); while if \( 3 \nmid x \), then \( 3 \mid (x^2 - 1) \).

(b) If \( x \) is even, then \( 4 \mid x^2 \); while if \( x \) is odd, then \( 8 \mid (x^2 - 1) \) and so \( 4 \mid (x^2 - 1) \).

Proof of Result 4.6(a).

Assume, first, that \( 3 \mid x \). Then \( x = 3q \) for some integer \( q \). Hence,
\[
x^2 = (3q)^2 = 9q^2.
\]
Since \( 9q^2 \in \mathbb{Z} \), it follows that \( 3 \mid x^2 \). Next, suppose that \( 3 \nmid x \). Then either \( x = 3q + 1 \) or \( x = 3q + 2 \) for some integer \( q \). We consider these two cases.

Case 1. \( x = 3q + 1 \) for some integer \( q \). Then
\[
x^2 - 1 = (3q + 1)^2 - 1 = (9q^2 + 6q + 1) - 1 = 9q^2 + 6q = 3(3q^2 + 2q).
\]
Since \( 3q^2 + 2q \) is an integer, \( 3 \mid (x^2 - 1) \).

Case 2. \( x = 3q + 2 \) for some integer \( q \). Then
\[
x^2 - 1 = (3q + 2)^2 - 1 = (9q^2 + 12q + 4) - 1 = 9q^2 + 12q + 1 = 3(3q^2 + 4q + 1).
\]
Since \( 3q^2 + 4q + 1 \) is an integer, \( 3 \mid (x^2 - 1) \).

Proof of Result 4.6(b).

First, assume that \( x \) is even. Then \( x = 2q \), where \( q \in \mathbb{Z} \). Thus, \( x^2 = (2q)^2 = 4q^2 \). Since \( q^2 \) is an integer, \( 4 \mid x^2 \). Next, suppose that \( x \) is odd. Then either \( x = 4q + 1 \) or \( x = 4q + 3 \) for some integer \( q \). We consider these two cases.

Case 1. \( x = 4q + 1 \) for some integer \( q \). Then
\[
x^2 - 1 = (4q + 1)^2 - 1 = (16q^2 + 8q + 1) - 1 = 16q^2 + 8q = 8(2q^2 + q).
\]
Since \( 2q^2 + q \) is an integer, \( 8 \mid (x^2 - 1) \).

Case 2. \( x = 4q + 3 \) for some integer \( q \). Then
\[
x^2 - 1 = (4q + 3)^2 - 1 = (16q^2 + 24q + 9) - 1 = 16q^2 + 24q + 8 = 8(2q^2 + 3q + 1).
\]
Since \( 2q^2 + 3q + 1 \in \mathbb{Z} \), it follows that \( 8 \mid (x^2 - 1) \).

We now consider a biconditional involving divisibility.

Result 4.7  Let \( x, y \in \mathbb{Z} \). Then \( 4 \mid (x^2 - y^2) \) if and only if \( x \) and \( y \) are of the same parity.

Proof  Assume first that \( x \) and \( y \) are of the same parity. We show that \( 4 \mid (x^2 - y^2) \). There are two cases.
4.1 Proofs Involving Divisibility of Integers

Case 1. \( x \) and \( y \) are both even. By Result 4.6(b), \( 4 \mid x^2 \) and \( 4 \mid y^2 \). Thus, \( x^2 = 4a \) and \( y^2 = 4b \) for some integers \( a \) and \( b \). Then

\[
x^2 - y^2 = 4a - 4b = 4(a - b).
\]

Since \( a - b \) is an integer, \( 4 \mid (x^2 - y^2) \).

Case 2. \( x \) and \( y \) are both odd. By Result 4.6(b), \( 4 \mid (x^2 - 1) \) and \( 4 \mid (y^2 - 1) \). Since \( 4 \mid (x^2 - 1) \) and \( 4 \mid (y^2 - 1) \), it follows by Result 4.3 that

\[
4 \mid [(1)(x^2 - 1) + (-1)(y^2 - 1)]
\]

and so \( 4 \mid (x^2 - y^2) \).

For the converse, assume that \( x \) and \( y \) are of opposite parity. We show that \( 4 \nmid (x^2 - y^2) \). There are two cases here as well.

Case 1. \( x \) is odd and \( y \) is even. By Result 4.6(b), \( 4 \mid (x^2 - 1) \) and \( 4 \mid y^2 \). Hence, \( x^2 - 1 = 4a \) and \( y^2 = 4b \), where \( a, b \in \mathbb{Z} \), and so \( x^2 = 4a + 1 \). Since

\[
x^2 - y^2 = (4a + 1) - 4b = 4(a - b) + 1,
\]

it follows that there is a remainder of 1 when \( x^2 - y^2 \) is divided by 4. Hence, \( 4 \nmid (x^2 - y^2) \).

Case 2. \( x \) is even and \( y \) is odd. The proof of this case is similar to that of Case 1 and is therefore omitted.

We saw in Theorem 3.17 for integers \( x \) and \( y \) that \( 2 \mid xy \) if and only if \( 2 \mid x \) or \( 2 \mid y \). We now verify a similar biconditional.

Result 4.8 Let \( x, y \in \mathbb{Z} \). Then \( 3 \mid xy \) if and only if \( 3 \mid x \) or \( 3 \mid y \).

Proof First, we show that if \( 3 \mid x \) or \( 3 \mid y \), then \( 3 \mid xy \). Assume that \( 3 \mid x \) or \( 3 \mid y \). Without loss of generality, we may assume that 3 divides \( x \). Then \( x = 3z \) for some integer \( z \). Hence, \( xy = (3z)y = 3(zy) \). Since \( zy \) is an integer, \( 3 \mid xy \).

Next, we use a proof by contrapositive to verify the converse. Assume that \( 3 \nmid x \) and \( 3 \nmid y \). Then either \( x = 3p + 1 \) or \( x = 3p + 2 \) for some integer \( p \) and \( y = 3q + 1 \) or \( y = 3q + 2 \) for some integer \( q \). There are four cases.

Case 1. \( x = 3p + 1 \) and \( y = 3q + 1 \), where \( p, q \in \mathbb{Z} \). Then

\[
xy = (3p + 1)(3q + 1) = 9pq + 3p + 3q + 1
\]

\[
= 3(3pq + p + q) + 1.
\]

Since \( 3pq + p + q \) is an integer, \( 3 \nmid xy \).

The proofs of the remaining cases are similar to the proof of Case 1 and are therefore omitted.

Case 2. \( x = 3p + 1 \) and \( y = 3q + 2 \), where \( p, q \in \mathbb{Z} \).

Case 3. \( x = 3p + 2 \) and \( y = 3q + 1 \), where \( p, q \in \mathbb{Z} \).

Case 4. \( x = 3p + 2 \) and \( y = 3q + 2 \), where \( p, q \in \mathbb{Z} \).
SECTION 4.1 EXERCISES

4.1. Let \(a\) and \(b\) be integers, where \(a \neq 0\). Prove that if \(a \mid b\), then \(a^2 \mid b^2\).

4.2. Let \(a, b \in \mathbb{Z}\), where \(a \neq 0\) and \(b \neq 0\). Prove that if \(a \mid b\) and \(b \mid a\), then \(a = b\) or \(a = -b\).

4.3. By Result 4.8, for integers \(x\) and \(y\), \(3 \mid xy\) if and only if \(3 \mid x\) or \(3 \mid y\). For integers \(x, y\) and \(z\), prove that \(3 \mid xyz\) if and only if \(3\) divides one of \(x, y\) and \(z\).

4.4. Let \(x, y \in \mathbb{Z}\). Prove that if \(3 \nmid x\) and \(3 \mid y\), then \(3 \mid (x^2 - y^2)\).

4.5. Let \(a, b, c \in \mathbb{Z}\), where \(a \neq 0\). Prove that if \(a \mid bc\), then \(a \mid b\) and \(a \mid c\).

4.6. Let \(a \in \mathbb{Z}\). Prove that if \(3 \mid 2a\), then \(3 \mid a\).

4.7. Let \(n \in \mathbb{Z}\). Prove that \(3 \mid (2n^2 + 1)\) if and only if \(3 \mid n\).

4.8. Let \(x \in \mathbb{Z}\). Prove that if \(2 \mid (x^2 - 5)\), then \(4 \mid (x^2 - 5)\).

4.9. Give an example of an integer \(x\) such that \(2 \mid (x^2 - 5)\) but \(8 \nmid (x^2 - 5)\).

4.10. Let \(n \in \mathbb{Z}\). Prove that \(2 \mid (n^2 - 3)\) if and only if \(4 \mid (n^2 + 3)\).

4.11. It is a consequence of Result 4.6(a) that if \(n\) is an odd integer such that \(3 \nmid n\), then \(3 \mid (n^2 - 1)\). Show, in fact, that if \(n\) is an odd integer such that \(3 \nmid n\), then \(24 \mid (n^2 - 1)\).

4.12. In Result 4.7, it was proved for integers \(x\) and \(y\) that \(4 \mid (x^2 - y^2)\) if and only if \(x\) and \(y\) are of the same parity. In particular, this says that if \(x\) and \(y\) are both even, then \(4 \mid (x^2 - y^2)\); while if \(x\) and \(y\) are both odd, then \(4 \mid (x^2 - y^2)\). Prove that if \(x\) and \(y\) are both odd, then \(8 \mid (x^2 - y^2)\).

4.13. Prove that if \(a, b, c \in \mathbb{Z}\) and \(a^2 + b^2 = c^2\), then \(3 \mid ab\).

4.2 PROOFS INVOLVING CONGRUENCE OF INTEGERS

We know that an integer \(x\) is even if \(x = 2q\) for some integer \(q\), while \(x\) is odd if \(x = 2q + 1\) for some integer \(q\). Furthermore, two integers \(x\) and \(y\) are of the same parity if they are both even or are both odd. From this, it follows that \(x\) and \(y\) are of the same parity if and only if \(2 \mid (x - y)\). Consequently, \(2 \mid (x - y)\) if and only if \(x\) and \(y\) have the same remainder when divided by 2. We also know that an integer \(x\) can be expressed as \(3q, 3q + 1\) or \(3q + 2\) for some integer \(q\) according to whether the remainder is 0, 1 or 2 when \(x\) is divided by 3. Furthermore, if two integers \(x\) and \(y\) are both of the form \(3q + 1\), then \(x = 3s + 1\) and \(y = 3t + 1\), where \(s, t \in \mathbb{Z}\), and so \(x - y = 3(s - t)\). Since \(s - t\) is an integer, \(3 \mid (x - y)\). Similarly, if \(x\) and \(y\) are both of the form \(3q\) or are both of the form \(3q + 2\), then \(3 \mid (x - y)\) as well. Hence, if \(x\) and \(y\) have the same remainder when divided by 3, then \(3 \mid (x - y)\). The converse of this implication is true as well. This suggests a special interest in pairs \(x, y\) of integers such that \(2 \mid (x - y)\) or \(3 \mid (x - y)\) or, in fact, in pairs \(x, y\) of integers such that \(n \mid (x - y)\) for some integer \(n \geq 2\).

For integers \(a, b\) and \(n \geq 2\), we say that \(a\) is congruent to \(b\) modulo \(n\), written \(a \equiv b \pmod{n}\), if \(n \mid (a - b)\). For example, \(15 \equiv 7 \pmod{4}\) since \(4 \mid (15 - 7)\) and \(3 \equiv -15 \pmod{9}\) since \(9 \mid (3 - (-15))\). On the other hand, 14 is not congruent to 4 modulo 6, written \(14 \not\equiv 4 \pmod{6}\), since \(6 \nmid (14 - 4)\).

Since we know that every integer \(x\) can be expressed as \(x = 2q\) or as \(x = 2q + 1\) for some integer \(q\), it follows that either \(2 \mid (x - 0)\) or \(2 \mid (x - 1)\), that is, \(x \equiv 0 \pmod{2}\) or \(x \equiv 1 \pmod{2}\) for every integer \(x\). Also, since each integer \(x\) can be expressed as \(x = 3q\),
4.2 Proofs Involving Congruence of Integers

Let $x = 3q + 1$ or $x = 3q + 2$ for some integer $q$, it follows that $3 \mid (x - 0)$, $3 \mid (x - 1)$ or $3 \mid (x - 2)$. Hence, for every integer $x$, either

$$x \equiv 0 \pmod{3}, \quad x \equiv 1 \pmod{3} \quad \text{or} \quad x \equiv 2 \pmod{3}.$$  

Moreover, for each integer $x$, exactly one of

$$x \equiv 0 \pmod{4}, \quad x \equiv 1 \pmod{4}, \quad x \equiv 2 \pmod{4}, \quad x \equiv 3 \pmod{4}$$  

holds, according to whether the remainder is 0, 1, 2 or 3, respectively, when $x$ is divided by 4. Similar statements can also be made when $x$ is divided by an integer $n \geq 5$.

We now consider some properties of congruence of integers.

**Result to Prove** Let $a$, $b$, $k$ and $n$ be integers where $n \geq 2$. If $a \equiv b \pmod{n}$, then $ka \equiv kb \pmod{n}$.

**PROOF STRATEGY** A direct proof seems reasonable here. So, we begin by assuming that $a \equiv b \pmod{n}$. Our goal is to show that $ka \equiv kb \pmod{n}$. Because we know that $a \equiv b \pmod{n}$, it follows from the definition that $n \mid (a - b)$, which implies that $a - b = nx$ for some integer $x$. We need to show that $ka \equiv kb \pmod{n}$, which means that we need to show that $n \mid (ka - kb)$. Thus, we must show that $ka - kb = nt$ for some integer $t$. This suggests considering the expression $ka - kb$.

**Result 4.9** Let $a$, $b$, $k$ and $n$ be integers where $n \geq 2$. If $a \equiv b \pmod{n}$, then $ka \equiv kb \pmod{n}$.

**Proof** Assume that $a \equiv b \pmod{n}$. Then $n \mid (a - b)$. Hence, $a - b = nx$ for some integer $x$. Therefore,

$$ka - kb = k(a - b) = k(nx) = n(kx).$$

Since $kx$ is an integer, $n \mid (ka - kb)$ and so $ka \equiv kb \pmod{n}$.

**Result 4.10** Let $a$, $b$, $c$, $d$, $n \in \mathbb{Z}$ where $n \geq 2$. If $a \equiv b \pmod{n}$ and $c \equiv d \pmod{n}$, then $a + c \equiv b + d \pmod{n}$.

**Proof** Assume that $a \equiv b \pmod{n}$ and $c \equiv d \pmod{n}$. Then $a - b = nx$ and $c - d = ny$ for some integers $x$ and $y$. Adding these two equations, we obtain

$$(a - b) + (c - d) = nx + ny$$

and so

$$(a + c) - (b + d) = n(x + y).$$

Since $x + y$ is an integer, $n \mid [(a + c) - (b + d)]$. Hence, $a + c \equiv b + d \pmod{n}$.

The next result parallels that of Result 4.10 in terms of multiplication.

**Result to Prove** Let $a$, $b$, $c$, $d$, $n \in \mathbb{Z}$ where $n \geq 2$. If $a \equiv b \pmod{n}$ and $c \equiv d \pmod{n}$, then $ac \equiv bd \pmod{n}$.

**PROOF STRATEGY** This result and Result 4.10 have the same hypothesis. In the proof of Result 4.10, we arrived at the equations $a - b = nx$ and $c - d = ny$ and needed only to add them to
complete the proof. This suggests that in the current result, it would be reasonable to multiply these two equations. However, if we multiply them, we obtain \((a - b)(c - d) = (nx)(ny)\), which does not give us the desired conclusion that \(ac - bd\) is a multiple of \(n\).

It is essential though that we work \(ac - bd\) into the proof. By rewriting \(a - b = nx\) and \(c - d = ny\) as \(a = b + nx\) and \(c = d + ny\), respectively, and then multiplying, we can accomplish this, however.

\[\therefore\]

**Result 4.11** Let \(a, b, c, d, n \in \mathbb{Z}\) where \(n \geq 2\). If \(a \equiv b \pmod{n}\) and \(c \equiv d \pmod{n}\), then \(ac \equiv bd \pmod{n}\).

**Proof** Assume that \(a \equiv b \pmod{n}\) and \(c \equiv d \pmod{n}\). Then \(a - b = nx\) and \(c - d = ny\), where \(x, y \in \mathbb{Z}\). Thus, \(a = b + nx\) and \(c = d + ny\). Multiplying these two equations, we obtain

\[ac = (b + nx)(d + ny) = bd + dnx + bny + n^2xy\]
\[= bd + n(dx + by + nxy)\]

and so \(ac - bd = n(dx + by + nxy)\). Since \(dx + by + nxy\) is an integer, \(ac \equiv bd \pmod{n}\).

We saw in Result 4.6(a) for an integer \(x\) that if \(3 | x\), then \(3 | x^2\); while if \(3 \nmid x\), then \(3 | (x^2 - 1)\). These facts can be expressed in terms of congruences.

**Result 4.12**

(a) For every integer \(n\), either \(n^2 \equiv 0 \pmod{3}\) or \(n^2 \equiv 1 \pmod{3}\).

(b) If \(n\) is an integer, then \(n^2 \equiv n \pmod{3}\) unless \(n \equiv 2 \pmod{3}\).

**Proof of Result 4.12(a).** By Result 4.6(a), if \(3 | n\), then \(3 | n^2\) and so \(n^2 \equiv 0 \pmod{3}\). If \(3 \nmid n\), then \(3 | (n^2 - 1)\). Thus, \(n^2 \equiv 1 \pmod{3}\).

**Proof of Result 4.12(b).** If \(3 | n\), then \(n \equiv 0 \pmod{3}\). Also, \(3 | n^2\) by Result 4.6(a) and so \(n^2 \equiv 0 \pmod{3}\). Hence, \(n^2 \equiv n \pmod{3}\). If \(n \equiv 1 \pmod{3}\), then \(3 \nmid n\) and so \(n^2 \equiv 1 \pmod{3}\) by Result 4.6(a). Hence, \(n^2 \equiv n \pmod{3}\). However, if \(n \equiv 2 \pmod{3}\), then \(n^2 \equiv 1 \pmod{3}\) by Result 4.6(a) and so \(n^2 \not\equiv n \pmod{3}\).

### SECTION 4.2 EXERCISES

4.14. Let \(a, b, n \in \mathbb{Z}\), where \(n \geq 2\). Prove that if \(a \equiv b \pmod{n}\), then \(a^2 \equiv b^2 \pmod{n}\).

4.15. Let \(a, b, c, n \in \mathbb{Z}\), where \(n \geq 2\). Prove that if \(a \equiv b \pmod{n}\) and \(a \equiv c \pmod{n}\), then \(b \equiv c \pmod{n}\).

4.16. Let \(a, b \in \mathbb{Z}\). Prove that \(a^2 + 2b^2 \equiv 0 \pmod{3}\) if and only if either \(a\) and \(b\) are both congruent to 0 modulo 3 or neither is congruent to 0 modulo 3.

4.17. (a) Prove that if \(a\) is an integer such that \(a \equiv 1 \pmod{5}\), then \(a^2 \equiv 1 \pmod{5}\).

(b) Given that \(b\) is an integer such that \(b \equiv 1 \pmod{5}\), what can we conclude from (a)?

4.18. Let \(m, n \in \mathbb{N}\) such that \(m \mid n\). Prove that if \(a\) and \(b\) are integers such that \(a \equiv b \pmod{n}\), then \(a \equiv b \pmod{m}\).
4.19. Let \( a, b \in \mathbb{Z} \). Show that if \( a \equiv 5 \pmod{6} \) and \( b \equiv 3 \pmod{4} \), then \( 4a + 6b \equiv 6 \pmod{8} \).

4.20. Prove that if \( n \) is an integer such that \( n \equiv 8 \pmod{9} \), then \( n^2 \equiv 1 \pmod{9} \).

4.21. Let \( a \in \mathbb{Z} \). Prove that \( a^3 \equiv a \pmod{3} \).

4.22. Let \( n \in \mathbb{Z} \). Prove each of the statements (a)–(f).
   
   (a) If \( n \equiv 0 \pmod{7} \), then \( n^2 \equiv 0 \pmod{7} \).
   (b) If \( n \equiv 1 \pmod{7} \), then \( n^2 \equiv 1 \pmod{7} \).
   (c) If \( n \equiv 2 \pmod{7} \), then \( n^2 \equiv 4 \pmod{7} \).
   (d) If \( n \equiv 3 \pmod{7} \), then \( n^2 \equiv 2 \pmod{7} \).
   (e) For each integer \( n \), \( n^2 \equiv (7 - n)^2 \pmod{7} \).
   (f) For every integer \( n \), \( n^2 \) is congruent to exactly one of 0, 1, 2 or 4 modulo 7.

4.23. Prove for any set \( S = \{a, a + 1, \ldots, a + 5\} \) of six integers where \( 6 \mid a \) that \( 24 \mid (x^2 - y^2) \) for distinct odd integers \( x \) and \( y \) in \( S \) if and only if one of \( x \) and \( y \) is congruent to 1 modulo 6 while the other is congruent to 5 modulo 6.

4.24. Let \( x \) and \( y \) be even integers. Prove that \( x^2 \equiv y^2 \pmod{16} \) if and only if either (a) \( x \equiv 0 \pmod{4} \) and \( y \equiv 0 \pmod{4} \) or (b) \( x \equiv 2 \pmod{4} \) and \( y \equiv 2 \pmod{4} \).

### 4.3 PROOFS INVOLVING REAL NUMBERS

We now apply the proof techniques we have introduced to verify some mathematical statements involving real numbers. To be certain that we are working under the same set of rules, let us recall some facts about real numbers whose truth we accept without justification. We have already mentioned that \( a^n \geq 0 \) for every real number \( a \). Indeed, \( a^n \geq 0 \) for every real number \( a \) if \( n \) is a positive even integer. If \( a < 0 \) and \( n \) is a positive odd integer, then \( a^n < 0 \). Of course, the product of two real numbers is positive if and only if both numbers are positive or both are negative.

Now let \( a, b, c \in \mathbb{R} \). If \( a \geq b \) and \( c \geq 0 \), then the inequality \( ac \geq bc \) holds. Indeed, if \( c > 0 \), then \( a/c \geq b/c \).

If \( a > b \) and \( c > 0 \), then \( ac > bc \) and \( a/c > b/c \). \hspace{1cm} (4.1)

If \( c < 0 \), then the inequalities in (4.1) are reversed; namely:

If \( a > b \) and \( c < 0 \), then \( ac < bc \) and \( a/c < b/c \). \hspace{1cm} (4.2)

Another important and well-known property of real numbers is that if the product of two real numbers is 0, then at least one of these numbers is 0.

**Theorem to Prove**

If \( x \) and \( y \) are real numbers such that \( xy = 0 \), then \( x = 0 \) or \( y = 0 \).

**Proof Strategy**

If we use a direct proof, then we begin by assuming that \( xy = 0 \). If \( x = 0 \), then we already have the desired result. On the other hand, if \( x \neq 0 \), then we are required to show that \( y = 0 \). However, if \( x \neq 0 \), then \( 1/x \) is a real number. This suggests multiplying \( xy = 0 \) by \( 1/x \).

**Theorem 4.13** Let \( x, y \in \mathbb{R} \). If \( xy = 0 \), then \( x = 0 \) or \( y = 0 \).
Chapter 4  More on Direct Proof and Proof by Contrapositive

Proof  Assume that $xy = 0$. We consider two cases, according to whether $x = 0$ or $x \neq 0$.

Case 1. $x = 0$. Then we have the desired conclusion.

Case 2. $x \neq 0$. Multiplying $xy = 0$ by the number $1/x$, we obtain
\[
\frac{1}{x}(xy) = \frac{1}{x} \cdot 0 = 0.
\]
Since
\[
\frac{1}{x}(xy) = \left(\frac{1}{x}\right)y = 1 \cdot y = y,
\]
it follows that $y = 0$.

Result 4.14  Let $x \in \mathbb{R}$. If $x^3 - 5x^2 + 3x = 15$, then $x = 5$.

Proof  Assume that $x^3 - 5x^2 + 3x = 15$. Thus, $x^3 - 5x^2 + 3x - 15 = 0$. Observe that
\[
x^3 - 5x^2 + 3x - 15 = x^2(x - 5) + 3(x - 5) = (x^2 + 3)(x - 5).
\]
Since $x^3 - 5x^2 + 3x - 15 = 0$, it follows that $(x^2 + 3)(x - 5) = 0$. By Theorem 4.13, $x^2 + 3 = 0$ or $x - 5 = 0$. Since $x^2 + 3 > 0$, it follows that $x - 5 = 0$ and so $x = 5$.

Next we consider an example of a proof by contrapositive involving an inequality.

Result 4.15  Let $x \in \mathbb{R}$. If $x^5 - 3x^4 + 2x^3 - x^2 + 4x - 1 \geq 0$, then $x \geq 0$.

Proof  Assume that $x < 0$. Then $x^5 < 0$, $2x^3 < 0$ and $4x < 0$. In addition, $-3x^4 < 0$ and $-x^2 < 0$. Thus,
\[
x^5 - 3x^4 + 2x^3 - x^2 + 4x - 1 < 0 - 1 < 0,
\]
as desired.

On occasion we may encounter problems that involve the verification of a certain equality or inequality and where it is convenient to find an equivalent formulation of the equality or inequality whose truth is clear. This then becomes the starting point of a proof. We now verify an inequality whose proof uses this common approach.

Result to Prove  If $x, y \in \mathbb{R}$, then
\[
\frac{1}{3}x^2 + \frac{3}{4}y^2 \geq xy.
\]

Proof Strategy  Let’s first eliminate fractions from the expression. Showing that $\frac{1}{3}x^2 + \frac{3}{4}y^2 \geq xy$ is equivalent to showing that
\[
12 \left(\frac{1}{3}x^2 + \frac{3}{4}y^2\right) \geq 12xy,
\]
that is,
\[
4x^2 + 9y^2 \geq 12xy,
\]
which, in turn, is equivalent to
\[ 4x^2 - 12xy + 9y^2 \geq 0. \]
That is, if we could show that \( 4x^2 - 12xy + 9y^2 \geq 0 \), then we would be able to show that
\[ \frac{1}{3}x^2 + \frac{3}{4}y^2 \geq xy. \]
Making a simple observation about \( 4x^2 - 12xy + 9y^2 \) leads to a proof.

\[ \blacksquare \]

**Result 4.16** If \( x, y \in \mathbb{R} \), then
\[ \frac{1}{3}x^2 + \frac{3}{4}y^2 \geq xy. \]

**Proof** Since \((2x - 3y)^2 \geq 0\), it follows that \( 4x^2 - 12xy + 9y^2 \geq 0 \) and so \( 4x^2 + 9y^2 \geq 12xy \).
Dividing this inequality by 12, we obtain
\[ \frac{1}{3}x^2 + \frac{3}{4}y^2 \geq xy, \]
producing the desired inequality.

Recall for a real number \( x \) that its **absolute value** \( |x| \) is defined as
\[
|x| = \begin{cases} 
  x & \text{if } x \geq 0 \\
  -x & \text{if } x < 0.
\end{cases}
\]
So, \(|5| = 5\), \(|0| = 0\) and \(|-3| = -(-3) = 3\). A well-known property of absolute values is that \(|xy| = |x||y|\) for every two real numbers \( x \) and \( y \) (see Exercise 4.30). The following theorem gives a familiar property of absolute values of real numbers (called the triangle inequality) that has numerous applications. Since the definition of \(|x|\) is essentially a definition by cases, proofs involving \(|x|\) are often by cases.

**Theorem 4.17** (The Triangle Inequality) For every two real numbers \( x \) and \( y \),
\[ |x + y| \leq |x| + |y|. \]

**Proof** Since \(|x + y| = |x| + |y|\) if either \( x \) or \( y \) is 0, we can assume that \( x \) and \( y \) are nonzero. We proceed by cases.

**Case 1.** \( x > 0 \) and \( y > 0 \). Then \( x + y > 0 \) and
\[ |x + y| = x + y = |x| + |y|. \]

**Case 2.** \( x < 0 \) and \( y < 0 \). Since \( x + y < 0 \),
\[ |x + y| = -(x + y) = (-x) + (-y) = |x| + |y|. \]

**Case 3.** One of \( x \) and \( y \) is positive and the other is negative. Assume, without loss of generality, that \( x > 0 \) and \( y < 0 \). We consider two subcases.
Chapter 4  More on Direct Proof and Proof by Contrapositive

Subcase 3.1. \( x + y \geq 0 \). Then
\[
|x| + |y| = x + (-y) = x - y > x + y = |x + y|.
\]

Subcase 3.2. \( x + y < 0 \). Here,
\[
|x| + |y| = x + (-y) = x - y > -x - y = -(x + y) = |x + y|.
\]
Therefore, \( |x + y| \leq |x| + |y| \) for every two real numbers.

Example 4.18  Show that if \( |x - 1| < 1 \) and \( |x - 1| < r/4 \), where \( r \in \mathbb{R}^+ \), then \( |x^2 + x - 2| < r \).

Solution  First, observe that
\[
|x^2 + x - 2| = |(x + 2)(x - 1)| = |x + 2||x - 1|.
\]
By Theorem 4.17,
\[
|x + 2| = |(x - 1) + 3| \leq |x - 1| + |3| < 1 + 3 = 4.
\]
Therefore,
\[
|x^2 + x - 2| = |x + 2||x - 1| < 4 \left( \frac{r}{4} \right) = r.
\]

SECTION 4.3 EXERCISES

4.25. Let \( x, y \in \mathbb{R} \). Prove that if \( x^2 - 4x = y^2 - 4y \) and \( x \neq y \), then \( x + y = 4 \).
4.26. Let \( a, b \) and \( m \) be integers. Prove that if \( 2a + 3b \geq 12m + 1 \), then \( a \geq 3m + 1 \) or \( b \geq 2m + 1 \).
4.27. Let \( x \in \mathbb{R} \). Prove that if \( 3x^4 + 1 \leq x^2 + x^3 \), then \( x > 0 \).
4.28. Prove that if \( r \) is a real number such that \( 0 < r < 1 \), then \( \frac{1}{r(1-r)} \geq 4 \).
4.29. Prove that if \( r \) is a real number such that \( |r - 1| < 1 \), then \( \frac{4}{r(4-r)} \geq 1 \).
4.30. Let \( x, y \in \mathbb{R} \). Prove that \( |xy| = |x| \cdot |y| \).
4.31. Prove for every two real numbers \( x \) and \( y \) that \( |x + y| \geq |x| - |y| \).
4.32. (a) Recall that \( \sqrt{r} > 0 \) for every positive real number \( r \). Prove that if \( a \) and \( b \) are positive real numbers, then \( 0 < \sqrt{ab} \leq \frac{a+b}{2} \). (The number \( \sqrt{ab} \) is called the geometric mean of \( a \) and \( b \), while \( (a + b)/2 \) is called the arithmetic mean or average of \( a \) and \( b \).)
(b) Under what conditions does \( \sqrt{ab} = (a + b)/2 \) for positive real numbers \( a \) and \( b \)? Justify your answer.
4.33. The geometric mean of three positive real numbers \( a, b \) and \( c \) is \( \sqrt[3]{abc} \). Prove that \( \sqrt[3]{abc} \leq (a + b + c)/3 \). [Note: The numbers \( a, b \) and \( c \) can be expressed as \( a = r^2 \), \( b = s^2 \) and \( c = t^2 \) for positive numbers \( r, s \) and \( t \).]
4.34. Prove for every three real numbers \( x, y \) and \( z \) that \( 1 + \frac{1}{x} \geq \frac{1}{x} + \frac{1}{y} \).
4.35. Prove that if \( x \) is a real number such that \( x(x + 1) > 2 \), then \( x < -2 \) or \( x > 1 \).
4.36. Prove for every positive real number \( x \) that \( 1 + \frac{1}{x} \geq \frac{1}{x} + \frac{1}{x^2} \).
4.37. Prove for \( x, y, z \in \mathbb{R} \) that \( x^2 + y^2 + z^2 \geq xy + xz + yz \).

4.38. Let \( a, b, x, y \in \mathbb{R} \) and \( r \in \mathbb{R}^+ \). Prove that if \( |x - a| < r/2 \) and \( |y - b| < r/2 \), then \( |(x + y) - (a + b)| < r \).

4.39. Prove that if \( a, b, c, d \in \mathbb{R} \), then \( (ab + cd)^2 \leq (a^2 + c^2)(b^2 + d^2) \).

### 4.4 PROOFS INVOLVING SETS

We now turn our attention to proofs concerning properties of sets. First, let’s recall some information about sets that was discussed in Chapter 1. For sets \( A \) and \( B \) contained in some universal set \( U \), the **intersection** of \( A \) and \( B \) is

\[
A \cap B = \{ x : x \in A \text{ and } x \in B \},
\]

the **union** of \( A \) and \( B \) is

\[
A \cup B = \{ x : x \in A \text{ or } x \in B \}
\]

and the **difference** of \( A \) and \( B \) is

\[
A - B = \{ x : x \in A \text{ and } x \notin B \}.
\]

The set \( A - B \) is also called the **relative complement** of \( B \) in \( A \) and the relative complement of \( A \) in \( U \) is called simply the **complement** of \( A \) and is denoted by \( \overline{A} \). Thus, \( \overline{A} = U - A \). In what follows, we will always assume that the sets under discussion are subsets of some universal set \( U \).

Figure 4.1 shows Venn diagrams of \( A - B \) and \( A \cap \overline{B} \) for arbitrary sets \( A \) and \( B \). The diagrams suggest that these two sets are equal. This is, in fact, the case. Recall that to show the equality of two sets \( C \) and \( D \), we can verify the two set inclusions \( C \subseteq D \) and \( D \subseteq C \). To establish the inclusion \( C \subseteq D \), we show that every element of \( C \) is also an element of \( D \), that is, if \( x \in C \) then \( x \in D \). This is accomplished with a direct proof by letting \( x \) be an (arbitrary) element of \( C \) and showing that \( x \) must belong to \( D \) as well. Recall that we need not be concerned if \( C \) contains no elements, for in this case \( C = \emptyset \) and \( C \subseteq D \).

![Venn diagrams](image_url_1)

**Figure 4.1** Venn diagrams for \( A - B \) and \( A \cap \overline{B} \)

**Result 4.19** For every two sets \( A \) and \( B \),

\[
A - B = A \cap \overline{B}.
\]
Chapter 4  More on Direct Proof and Proof by Contrapositive

Proof First, we show that $A - B \subseteq A \cap \overline{B}$. Let $x \in A - B$. Then $x \in A$ and $x \notin B$. Since $x \notin B$, it follows that $x \in \overline{B}$. Therefore, $x \in A$ and $x \in \overline{B}$; so $x \in A \cap \overline{B}$. Hence, $A - B \subseteq A \cap \overline{B}$.

Next, we show that $A \cap \overline{B} \subseteq A - B$. Let $y \in A \cap \overline{B}$. Then $y \in A$ and $y \notin \overline{B}$. Since $y \notin \overline{B}$, we see that $y \in B$. Now, because $y \in A$ and $y \notin B$, we conclude that $y \in A - B$. Thus, $A \cap \overline{B} \subseteq A - B$.

Proof Analysis In the second paragraph of the proof of Result 4.19, we used $y$ (rather than $x$) to denote an arbitrary element of $A \cap \overline{B}$. We did this only for variety. We could have used $x$ twice. Once we decided to use distinct symbols, $y$ was the logical choice since $x$ was used in the first paragraph of the proof. This keeps our use of symbols consistent. Another possibility would have been to use $a$ in the first paragraph and $b$ in the second. This has some disadvantages, however. Since the sets are being called $A$ and $B$, we might have a tendency to think that $a \in A$ and $b \in B$, which may confuse the reader. For this reason, we chose $x$ and $y$ over $a$ and $b$.

Before leaving the proof of Result 4.19, we have one other remark. At one point in the second paragraph, we learned that $y \in A$ and $y \notin B$. From this we could have concluded (correctly) that $y \notin A \cap B$, but this is not what we wanted. Instead, we wrote that $y \in A - B$. It is always a good idea to keep our goal in sight. We wanted to show that $y \in A - B$; so it was important to keep in mind that it was the set $A - B$ in which we were interested, not $A \cap B$.

Next, let’s consider the Venn diagrams for $(A \cup B) - (A \cap B)$ and $(A - B) \cup (B - A)$, which are shown in Figure 4.2. From these two diagrams, we might conclude (correctly) that the two sets $(A \cup B) - (A \cap B)$ and $(A - B) \cup (B - A)$ are equal. Indeed, all that is lacking is a proof that these two sets are equal. That is, Venn diagrams can be useful in suggesting certain results concerning sets but they are only drawings and do not constitute a proof.

![Venn Diagrams](image)

Figure 4.2  Venn diagrams for $(A \cup B) - (A \cap B)$ and $(A - B) \cup (B - A)$

Result 4.20  For every two sets $A$ and $B$,

$$(A \cup B) - (A \cap B) = (A - B) \cup (B - A).$$

Proof First, we show that $(A \cup B) - (A \cap B) \subseteq (A - B) \cup (B - A)$. Let $x \in (A \cup B) - (A \cap B)$. Then $x \in A \cup B$ and $x \notin A \cap B$. Since $x \in A \cup B$, it follows that $x \in A$ or $x \in B$. Without
4.4 Proofs Involving Sets

loss of generality, we can assume \( x \in A \). Since \( x \notin A \cap B \), the element \( x \notin B \). Therefore, \( x \in A - B \) and so \( x \in (A - B) \cup (B - A) \). Hence,

\[
(A \cup B) - (A \cap B) \subseteq (A - B) \cup (B - A).
\]

Next, we show that \((A - B) \cup (B - A) \subseteq (A \cup B) - (A \cap B)\). Let \( x \in (A - B) \cup (B - A) \). Then \( x \in A - B \) or \( x \in B - A \), say the former. So, \( x \in A \) and \( x \notin B \). Thus, \( x \in A \cup B \) and \( x \notin A \cap B \). Consequently, \( x \in (A \cup B) - (A \cap B) \). Therefore,

\[
(A - B) \cup (B - A) \subseteq (A \cup B) - (A \cap B),
\]
as desired.

**Proof Analysis**

In the proof of Result 4.20, when we were verifying the set inclusion

\[
(A \cup B) - (A \cap B) \subseteq (A - B) \cup (B - A),
\]
we concluded that \( x \in A \) or \( x \in B \). At that point, we could have divided the proof into two cases (Case 1. \( x \in A \) and Case 2. \( x \in B \)); however, the proofs of the two cases would be identical, except that \( A \) and \( B \) would be interchanged. Therefore, we decided to consider only one of these. Since it really didn’t matter which case we handled, we simply chose the case where \( x \in A \). This was accomplished by writing:

*Without loss of generality, assume that \( x \in A \).*

In the proof of the reverse set containment, we found ourselves in a similar situation, namely, \( x \in A - B \) or \( x \in B - A \). Again, these two situations were basically identical and we simply chose to work with the first (former) situation. (Had we decided to assume that \( x \in B - A \), we would have considered the latter case.)

We now look at an example of a biconditional concerning sets.

**Result 4.21** Let \( A \) and \( B \) be sets. Then \( A \cup B = A \) if and only if \( B \subseteq A \).

**Proof** First, we show that if \( A \cup B = A \), then \( B \subseteq A \). We use a proof by contrapositive. Assume that \( B \) is not a subset of \( A \). Then there must be some element \( x \in B \) such that \( x \notin A \). Since \( x \in B \), it follows that \( x \in A \cup B \). However, since \( x \notin A \), we have \( A \cup B \neq A \).

Next, we verify the converse, namely, if \( B \subseteq A \), then \( A \cup B = A \). We use a direct proof here. Assume that \( B \subseteq A \). To verify that \( A \cup B = A \), we show that \( A \subseteq A \cup B \) and \( A \cup B \subseteq A \). The set inclusion \( A \subseteq A \cup B \) is immediate (if \( x \in A \), then \( x \in A \cup B \)). It remains only to show that \( A \cup B \subseteq A \). Let \( y \in A \cup B \). Thus, \( y \in A \) or \( y \in B \). If \( y \in A \), then we already have the desired result. If \( y \in B \), then since \( B \subseteq A \), it follows that \( y \in A \). Thus, \( A \cup B \subseteq A \).

**Proof Analysis** In the first paragraph of the proof of Result 4.21 we indicated that we were using a proof by contrapositive, while in the second paragraph we mentioned that we were using a direct proof. This really wasn’t necessary as the assumptions we made would inform the reader what technique we were applying. Also, in the proof of Result 4.21, we used a proof by contrapositive for one implication and a direct proof for its converse. This wasn’t necessary either. Indeed, it is quite possible to interchange the techniques we used (see Exercise 4.41).
SECTION 4.4 EXERCISES

4.40. Let $A$ and $B$ be sets. Prove that $A \cup B = (A - B) \cup (B - A) \cup (A \cap B)$.

4.41. In Result 4.21, it was proved for sets $A$ and $B$ that $A \cup B = A$ if and only if $B \subseteq A$. Provide another proof of this result by giving a direct proof of the implication “If $A \cup B = A$, then $B \subseteq A$” and a proof by contrapositive of its converse.

4.42. Let $A$ and $B$ be sets. Prove that $A \cap B = A$ if and only if $A \subseteq B$.

4.43. (a) Give an example of three sets $A$, $B$ and $C$ such that $A \cap B = A \cap C$ but $B \neq C$.
   (b) Give an example of three sets $A$, $B$ and $C$ such that $A \cup B = A \cup C$ but $B \neq C$.
   (c) Let $A$, $B$ and $C$ be sets. Prove that if $A \cap B = A \cap C$ and $A \cup B = A \cup C$, then $B = C$.

4.44. Prove that if $A$ and $B$ are sets such that $A \cup B \neq \emptyset$, then $A \neq \emptyset$ or $B \neq \emptyset$.

4.45. Let $A = \{n \in \mathbb{Z} : n \equiv 1 \pmod{2}\}$ and $B = \{n \in \mathbb{Z} : n \equiv 3 \pmod{4}\}$. Prove that $B \subseteq A$.

4.46. Let $A$ and $B$ be sets. Prove that $A \cup B = A \cap B$ if and only if $A = B$.

4.47. Let $A = \{n \in \mathbb{Z} : n \equiv 2 \pmod{3}\}$ and $B = \{n \in \mathbb{Z} : n \equiv 1 \pmod{2}\}$.
   (a) Describe the elements of the set $A - B$.
   (b) Prove that if $n \in A \cap B$, then $n^2 \equiv 1 \pmod{12}$.

4.48. Let $A = \{n \in \mathbb{Z} : 2 | n\}$ and $B = \{n \in \mathbb{Z} : 4 | n\}$. Let $n \in \mathbb{Z}$. Prove that $n \in A - B$ if and only if $n = 2k$ for some odd integer $k$.

4.49. Prove for every two sets $A$ and $B$ that $A = (A - B) \cup (A \cap B)$.

4.50. Prove for every two sets $A$ and $B$ that $A - B$, $B - A$ and $A \cap B$ are pairwise disjoint.

4.51. Let $A$ and $B$ be subsets of a universal set. Which of the following is a necessary condition for $A$ and $B$ to be disjoint?
   (a) Either $A = \emptyset$ or $B = \emptyset$.
   (b) Whenever $x \notin A$, it must occur that $x \in B$.
   (c) Whenever $x \notin A$, it must occur that $x \notin B$.
   (d) Whenever $x \in A$, it must occur that $x \in B$.
   (e) Whenever $x \in A$, it must occur that $x \notin B$.

4.5 FUNDAMENTAL PROPERTIES OF SET OPERATIONS

Many results concerning sets follow from some very fundamental properties of sets which, in turn, follow from corresponding results about logical statements that were described in Chapter 2. For example, we know that if $P$ and $Q$ are two statements, then $P \lor Q$ and $Q \lor P$ are logically equivalent. Similarly, if $A$ and $B$ are two sets, then $A \cup B = B \cup A$. We list some of the fundamental properties of set operations in the following theorem.

Theorem 4.22 For sets $A$, $B$ and $C$,

1. **Commutative Laws**
   (a) $A \cup B = B \cup A$
   (b) $A \cap B = B \cap A$
4.5 Fundamental Properties of Set Operations

(2) **Associative Laws**
   
   (a) \( A \cup (B \cup C) = (A \cup B) \cup C \)
   
   (b) \( A \cap (B \cap C) = (A \cap B) \cap C \)

(3) **Distributive Laws**

   (a) \( A \cup (B \cap C) = (A \cup B) \cap (A \cup C) \)

   (b) \( A \cap (B \cup C) = (A \cap B) \cup (A \cap C) \)

(4) **De Morgan’s Laws**

   (a) \( \overline{A \cup B} = \overline{A} \cap \overline{B} \)

   (b) \( \overline{A \cap B} = \overline{A} \cup \overline{B} \).

We present proofs of only three parts of Theorem 4.22, beginning with the commutative law of the union of two sets.

**Proof of Theorem 4.22(1a)**

We show that \( A \cup B \subseteq B \cup A \). Assume that \( x \in A \cup B \). Then \( x \in A \) or \( x \in B \). Applying the commutative law for conjunction of statements, we conclude that \( x \in B \) or \( x \in A \); so \( x \in B \cup A \). Thus, \( A \cup B \subseteq B \cup A \). The proof of the reverse set inclusion \( B \cup A \subseteq A \cup B \) is similar and is therefore omitted.

Next we verify one of the distributive laws.

**Proof of Theorem 4.22(3a)**

First, we show that \( A \cup (B \cap C) \subseteq (A \cup B) \cap (A \cup C) \). Let \( x \in A \cup (B \cap C) \). Then \( x \in A \) or \( x \in B \cap C \). If \( x \in A \), then \( x \in A \cup B \) and \( x \in A \cup C \). Thus, \( x \in (A \cup B) \cap (A \cup C) \), as desired. On the other hand, if \( x \in B \cap C \), then \( x \in B \) and \( x \in C \); and again, \( x \in A \cup B \) and \( x \in A \cup C \). So, \( x \in (A \cup B) \cap (A \cup C) \). Therefore, \( A \cup (B \cap C) \subseteq (A \cup B) \cap (A \cup C) \).

To verify the reverse set inclusion, let \( x \in (A \cup B) \cap (A \cup C) \). Then \( x \in A \cup B \) and \( x \in A \cup C \). If \( x \in A \), then \( x \in A \cup (B \cap C) \). So, we may assume that \( x \notin A \). Then the fact that \( x \in A \cup B \) and \( x \notin A \) implies that \( x \in B \). By the same reasoning, \( x \in C \). Thus, \( x \in B \cap C \) and so \( x \in A \cup (B \cap C) \). Therefore, \( (A \cup B) \cap (A \cup C) \subseteq A \cup (B \cap C) \).

As a final example, we prove one of De Morgan’s laws.

**Proof of Theorem 4.22(4a)**

First, we show that \( \overline{A \cup B} \subseteq \overline{A} \cap \overline{B} \). Let \( x \in \overline{A \cup B} \). Then \( x \notin A \cup B \). Hence, \( x \notin A \) and \( x \notin B \). Therefore, \( x \notin \overline{A} \) and \( x \notin \overline{B} \); so \( x \notin \overline{A} \cap \overline{B} \). Consequently, \( \overline{A \cup B} \subseteq \overline{A} \cap \overline{B} \).

Next, we show that \( \overline{A \cap B} \subseteq \overline{A} \cup \overline{B} \). Let \( x \in \overline{A \cap B} \). Then \( x \notin A \) and \( x \notin B \). Thus, \( x \notin A \) and \( x \notin B \); so \( x \notin A \cup B \). Therefore, \( x \in \overline{A \cup B} \). Hence, \( \overline{A} \cap \overline{B} \subseteq \overline{A} \cup \overline{B} \).

**PROOF ANALYSIS**

In the proof of the De Morgan law that we just presented, we arrived at the step \( x \notin A \cup B \) at one point and then next wrote \( x \notin A \) and \( x \notin B \). Since \( x \in A \cup B \) implies that \( x \notin A \) or \( x \notin B \), you might have expected us to write that \( x \notin A \) or \( x \notin B \) after writing \( x \notin A \cup B \), but this would not be the correct conclusion. When we say that \( x \notin A \cup B \), this is equivalent to writing \( \sim (x \in A \cup B) \), which is logically equivalent to \( \sim ((x \in A) \lor (x \in B)) \). By the De Morgan law for the negation of the disjunction of two statements (or two open sentences), we have that \( \sim ((x \in A) \lor (x \in B)) \) is logically equivalent to \( \sim (x \in A) \) and \( \sim (x \in B) \); that is, \( x \notin A \) and \( x \notin B \).

Proofs of some other parts of Theorem 4.22 are left as exercises.
SECTION 4.5 EXERCISES

4.52. Prove that \( A \cap B = B \cap A \) for every two sets \( A \) and \( B \) (Theorem 4.22(1b)).

4.53. Prove that \( A \cap (B \cup C) = (A \cap B) \cup (A \cap C) \) for every three sets \( A, B \) and \( C \) (Theorem 4.22(3b)).

4.54. Prove that \( \overline{A \cap B} = \overline{A} \cup \overline{B} \) for every two sets \( A \) and \( B \) (Theorem 4.22(4b)).

4.55. Let \( A, B \) and \( C \) be sets. Prove that \( (A - B) \cap (A - C) = A - (B \cup C) \).

4.56. Let \( A, B \) and \( C \) be sets. Prove that \( (A - B) \cup (A - C) = A - (B \cap C) \).

4.57. Let \( A, B \) and \( C \) be sets. Use Theorem 4.22 to prove that \( \overline{A \cup (B \cap C)} = (A \cap B) \cup (A - C) \).

4.58. Let \( A, B \) and \( C \) be sets. Prove that \( A \cap (B \cap C) = (A \cup B) \cap (A \cup C) \).

4.59. Show for every three sets \( A, B \) and \( C \) that \( A - (B - C) = (A \cap C) \cup (A - B) \).

4.6 PROOFS INVOLVING CARTESIAN PRODUCTS OF SETS

Recall that the **Cartesian product** (or simply the **product**) \( A \times B \) of two sets \( A \) and \( B \) is defined as

\[
A \times B = \{(a, b) : a \in A \text{ and } b \in B \}.
\]

If \( A = \emptyset \) or \( B = \emptyset \), then \( A \times B = \emptyset \).

Before looking at several examples of proofs concerning Cartesian products of sets, it is important to keep in mind that an arbitrary element of the Cartesian product \( A \times B \) of two sets \( A \) and \( B \) is of the form \((a, b)\), where \( a \in A \) and \( b \in B \).

**Result 4.23** Let \( A, B, C \) and \( D \) be sets. If \( A \subseteq C \) and \( B \subseteq D \), then \( A \times B \subseteq C \times D \).

**Proof** Let \((x, y) \in A \times B\). Then \( x \in A \) and \( y \in B \). Since \( A \subseteq C \) and \( B \subseteq D \), it follows that \( x \in C \) and \( y \in D \). Hence, \((x, y) \in C \times D \).

**Result 4.24** For sets \( A, B \) and \( C \),

\[
A \times (B \cup C) = (A \times B) \cup (A \times C).
\]

**Proof** We first show that \( A \times (B \cup C) \subseteq (A \times B) \cup (A \times C) \). Let \((x, y) \in A \times (B \cup C)\). Then \( x \in A \) and \( y \in B \cup C \). Thus, \( y \in B \) or \( y \in C \), say the former. Then \((x, y) \in A \times B \) and so \((x, y) \in (A \times B) \cup (A \times C) \). Consequently, \( A \times (B \cup C) \subseteq (A \times B) \cup (A \times C) \).

Next, we show that \( (A \times B) \cup (A \times C) \subseteq A \times (B \cup C) \). Let \((x, y) \in (A \times B) \cup (A \times C) \). Then \((x, y) \in A \times B \) or \((x, y) \in A \times C \), say the former. Then \( x \in A \) and \( y \in B \subseteq B \cup C \). Hence, \((x, y) \in A \times (B \cup C) \), implying that \( (A \times B) \cup (A \times C) \subseteq A \times (B \cup C) \).

We give one additional example of a proof involving the Cartesian products of sets.

**Result 4.25** For sets \( A, B \) and \( C \),

\[
A \times (B - C) = (A \times B) - (A \times C).
\]
First, we show that \( A \times (B - C) \subseteq (A \times B) - (A \times C) \). Let \((x, y) \in A \times (B - C)\). Then \( x \in A \) and \( y \in B - C \). Since \( y \in B - C \), it follows that \( y \in B \) and \( y \notin C \). Because \( x \in A \) and \( y \in B \), we have \((x, y) \in A \times B \). Since \( y \notin C \), however, \((x, y) \notin A \times C \). Therefore, \((x, y) \in (A \times B) - (A \times C)\). Hence, \( A \times (B - C) \subseteq (A \times B) - (A \times C) \).

We now show that \((A \times B) - (A \times C) \subseteq A \times (B - C)\). Let \((x, y) \in (A \times B) - (A \times C)\). Then \((x, y) \in A \times B \) and \((x, y) \notin A \times C \). Since \((x, y) \in A \times B \), it follows that \( x \in A \) and \( y \in B \). Also, since \( x \in A \) and \((x, y) \notin A \times C \), it follows that \( y \notin C \). So, \( y \in B - C \). Thus, \((x, y) \in A \times (B - C) \) and \((A \times B) - (A \times C) \subseteq A \times (B - C)\).

**PROOF ANALYSIS** We add one comment concerning the preceding proof. During the proof of \((A \times B) - (A \times C) \subseteq A \times (B - C)\), we needed to show that \( y \notin C \). We learned that \((x, y) \notin A \times C \). However, this information alone did not allow us to conclude that \( y \notin C \). Indeed, if \((x, y) \notin A \times C \), then \( x \notin A \) or \( y \notin C \). Since we knew, however, that \( x \in A \) and \( (x, y) \notin A \times C \), we were able to conclude that \( y \notin C \).

### SECTION 4.6 EXERCISES

4.60. For \( A = \{x, y\} \), determine \( A \times \mathcal{P}(A) \).

4.61. For \( A = \{1\} \) and \( B = \{2\} \), determine \( \mathcal{P}(A \times B) \) and \( \mathcal{P}(A) \times \mathcal{P}(B) \).

4.62. Let \( A \) and \( B \) be sets. Prove that \( A \times B = \emptyset \) if and only if \( A = \emptyset \) or \( B = \emptyset \).

4.63. For sets \( A \) and \( B \), find a necessary and sufficient condition for \( A \times B = B \times A \).

4.64. For sets \( A \) and \( B \), find a necessary and sufficient condition for \( (A \times B) \cap (B \times A) = \emptyset \). Verify that this condition is necessary and sufficient.

4.65. Let \( A, B \) and \( C \) be nonempty sets. Prove that \( A \times C \subseteq B \times C \) if and only if \( A \subseteq B \).

4.66. Result 4.23 states that if \( A, B, C \) and \( D \) are sets such that \( A \subseteq C \) and \( B \subseteq D \), then \( A \times B \subseteq C \times D \).

(a) Show that the converse of Result 4.23 is false.

(b) Under what added hypothesis is the converse true? Prove your assertion.

4.67. Let \( A, B \) and \( C \) be sets. Prove that \( A \times (B \cap C) = (A \times B) \cap (A \times C) \).

4.68. Let \( A, B, C \) and \( D \) be sets. Prove that \( (A \times B) \cap (C \times D) = (A \cap C) \times (B \cap D) \).

4.69. Let \( A, B, C \) and \( D \) be sets. Prove that \( (A \times B) \cup (C \times D) \subseteq (A \cup C) \times (B \cup D) \).

4.70. Let \( A \) and \( B \) be sets. Show, in general, that \( \overline{A \times B} \neq \overline{A} \times \overline{B} \).

### Chapter 4 Supplemental Exercises

4.71. Let \( n \in \mathbb{Z} \). Prove that \( 5 \mid n^2 \) if and only if \( 5 \mid n \).

4.72. Prove that if \( a, b \) and \( c \) are nonzero integers such that \( a \mid b, b \mid c \) and \( c \mid a \), then at least two of \( a, b \) and \( c \) are equal.

4.73. Prove that if \( n \) is an odd integer, then \( 8 \mid (n^2 + (n + 6)^2 + 6) \).

4.74. Prove that if \( n \) is an odd integer, then \( 8 \mid (n^4 + 4n^2 + 11) \).
Chapter 4  More on Direct Proof and Proof by Contrapositive

4.75. Let \( n, m \in \mathbb{Z} \). Prove that if \( n \equiv 1 \pmod{2} \) and \( m \equiv 3 \pmod{4} \), then \( n^2 + m \equiv 0 \pmod{4} \).

4.76. Find two distinct positive integer values of \( a \) for which the following is true and give a proof in each case:

For every integer \( n \), \( a \nmid (n^2 + 1) \).

4.77. Prove for every two real numbers \( a \) and \( b \) that \( ab \leq \sqrt{a^2 \sqrt{b^2}} \).

4.78. Prove for every two positive real numbers \( a \) and \( b \) that \( a^b + b^a \geq 2 \).

4.79. Prove the following: Let \( x \in \mathbb{R} \). If \( x(x-5) = -4 \), then \( \sqrt{5x^2 - 4} = 1 \) implies that \( x + \frac{1}{x} = 2 \).

4.80. Let \( x, y \in \mathbb{R} \). Prove that if \( x < 0 \), then \( x^3 - x^2 y \leq x^2 y - xy^2 \).

4.81. Prove that 3 \( | \) \( (n^3 - 4n) \) for every integer \( n \).

4.82. Evaluate the proposed proof of the following result.

**Result**  Let \( x, y \in \mathbb{Z} \). If \( x \equiv 2 \pmod{3} \) and \( y \equiv 2 \pmod{3} \), then \( xy \equiv 1 \pmod{3} \).

**Proof**  Let \( x \equiv 2 \pmod{3} \) and \( y \equiv 2 \pmod{3} \). Then \( x = 3k + 2 \) and \( y = 3k + 2 \) for some integer \( k \). Hence,

\[
xy = (3k + 2)(3k + 2) = 9k^2 + 12k + 4 = 9k^2 + 12k + 3 + 1
\]

\[
= 3(3k^2 + 4k + 1) + 1.
\]

Since \( 3k^2 + 4k + 1 \) is an integer, \( xy \equiv 1 \pmod{3} \).

4.83. Below is given a proof of a result. What result is proved?

**Proof**  Assume that \( x \equiv 1 \pmod{5} \) and \( y \equiv 2 \pmod{5} \). Then \( 5 \mid (x - 1) \) and \( 5 \mid (y - 2) \). Hence, \( x - 1 = 5a \) and \( y - 2 = 5b \) for some integers \( a \) and \( b \). So, \( x = 5a + 1 \) and \( y = 5b + 2 \). Therefore,

\[
x^2 + y^2 = (5a + 1)^2 + (5b + 2)^2 = (25a^2 + 10a + 1) + (25b^2 + 20b + 4)
\]

\[
= 25a^2 + 10a + 25b^2 + 20b + 5 = 5(5a^2 + 2a + 5b^2 + 4b + 1).
\]

Since \( 5a^2 + 2a + 5b^2 + 4b + 1 \) is an integer, \( 5 \mid (x^2 + y^2) \) and so \( x^2 + y^2 \equiv 0 \pmod{5} \).

4.84. A proof of the following result is given.

**Result**  Let \( n \in \mathbb{Z} \). If \( n^4 \) is even, then \( 3n + 1 \) is odd.

**Proof**  Assume that \( n^4 = (n^2)^2 \) is even. Since \( n^4 \) is even, \( n^2 \) is even. Furthermore, since \( n^2 \) is even, \( n \) is even. Because \( n \) is even, \( n = 2k \) for some integer \( k \). Then

\[
3n + 1 = 3(2k) + 1 = 6k + 1 = 2(3k) + 1.
\]

Since \( 3k \) is an integer, \( 3n + 1 \) is odd.

Answer the following questions.

1. Which proof technique is being used?
2. What is the starting assumption?
3. What should be mentioned in a complete proof?
4. Give a reason for each of the following steps in the proof.

   a. Since \( n^4 \) is even, \( n^2 \) is even.
   b. Furthermore, since \( n^2 \) is even, \( n \) is even.
Chapter 4 Supplemental Exercises

4.85. Given below is an attempted proof of a result.

**Proof** First, we show that \( A \subseteq (A \cup B) - B \). Let \( x \in A \). Since \( A \cap B = \emptyset \), it follows that \( x \notin B \). Therefore, \( x \in A \cup B \) and \( x \notin B \); so \( x \in (A \cup B) - B \). Thus, \( A \subseteq (A \cup B) - B \).

Next, we show that \((A \cup B) - B \subseteq A \). Let \( x \in (A \cup B) - B \). Then \( x \in A \cup B \) and \( x \notin B \). From this, it follows that \( x \in A \). Hence, \((A \cup B) - B \subseteq A \).

(a) What result is being proved above?

(b) What change (or changes) in this proof would make it better (from your point of view)?

4.86. Evaluate the proposed proof of the following result.

**Result** Let \( x, y \in \mathbb{Z} \) such that \( 3 \mid x \). If \( 3 \mid (x + y) \), then \( 3 \mid y \).

**Proof** Since \( 3 \mid x \), it follows that \( x = 3a \), where \( a \in \mathbb{Z} \). Assume that \( 3 \mid (x + y) \).

Then \( x + y = 3b \) for some integer \( b \). Hence, \( y = 3b - x = 3b - 3a = 3(b - a) \).

Since \( b - a \) is an integer, \( 3 \mid y \).

For the converse, assume that \( 3 \mid y \). Therefore, \( y = 3c \), where \( c \in \mathbb{Z} \). Thus, \( x + y = 3a + 3c = 3(a + c) \). Since \( a + c \) is an integer, \( 3 \mid (x + y) \).

4.87. Evaluate the proposed proof of the following result.

**Result** Let \( x, y \in \mathbb{Z} \). If \( x \equiv 1 \pmod{3} \) and \( y \equiv 1 \pmod{3} \), then \( xy \equiv 1 \pmod{3} \).

**Proof** Assume that \( x \equiv 1 \pmod{3} \) and \( y \equiv 1 \pmod{3} \). Then \( 3 \mid (x - 1) \) and \( 3 \mid (y - 1) \).

Hence, \( x - 1 = 3q \) and \( y - 1 = 3r \) for some integer \( q \) and so \( x = 3q + 1 \) and \( y = 3r + 1 \). Thus,

\[
xy = (3q + 1)(3r + 1) = 9q^2 + 6q + 1 = 3(3q^2 + 2q) + 1
\]

and so \( xy - 1 = 3(3q^2 + 2q) \). Since \( 3q^2 + 2q \) is an integer, \( 3 \mid (xy - 1) \). Hence, \( xy \equiv 1 \pmod{3} \).

4.88. Evaluate the proposed proof of the following result.

**Result** For every three sets \( A, B \) and \( C \), \((A \times C) - (B \times C) \subseteq (A - B) \times C \).

**Proof** Let \((x, y) \in (A \times C) - (B \times C) \). Then \((x, y) \in A \times C \) and \((x, y) \notin B \times C \).

Since \((x, y) \in A \times C \), it follows that \( x \in A \) and \( y \in C \). Since \((x, y) \notin B \times C \), we have \( x \notin B \). Thus, \( x \in A - B \). Hence, \((x, y) \in (A - B) \times C \).

4.89. Let \( a \in \mathbb{Z} \). Prove that if \( 3 \mid 5a \), then \( 3 \mid a \).

4.90. Let \( a, b, c, d \in \mathbb{R} \). Prove that if \( a \geq b \geq 0 \) and \( c \geq d \geq 0 \), then \( ac \geq bd \).

4.91. Let \( a \in \mathbb{R}^+ \). Prove that if \( a < 1 \), then \( \sqrt{a} > a \).

4.92. Prove that if \( x, y, z \in \mathbb{R} \), then \( |x - y| - |y - z| \geq |x - z| \).

4.93. Let \( A \) and \( B \) be two sets. Prove that \((A \times B) \cap (B \times A) = (A \cap B) \times (B \cap A) \).

4.94. Let \( n_1, n_2 \) and \( n_3 \) be three integers such that \( 3 \nmid n_i \) for \( i = 1, 2, 3 \). Prove that if \( 3 \) does not divide the sum of any two of these three integers, then \( 3 \) divides the sum of all three integers.
4.95. Prove that for every three integers \( a, b \) and \( c \), the sum \(|a - b| + |a - c| + |b - c|\) is an even integer.

4.96. Prove for every four real numbers \( a, b, c \) and \( d \) that \( ac + bd \leq \sqrt{a^2 + b^2} \sqrt{c^2 + d^2} \).

4.97. Prove that for every real number \( x \), \( \sin^6 x + 3 \sin^2 x \cos^2 x + \cos^6 x = 1 \).

4.98. Let \( a \in \mathbb{Z} \). Prove that if \( 6 \mid a \) and \( 10 \mid a \), then \( 15 \mid a \).

4.99. Let \( A = \{x\} \). Give an example of a set concerning the set \( A \) to which each of the following elements belong.

(a) \( x, \{x\} \)  
(b) \( \{x\}, x \)  
(c) \( x, x \)  
(d) \( \{x\}, \{x\} \)  
(e) \( x \)  
(f) \( \{x\} \)  
(g) \( \{\{x, x\}\} \)  
(h) \( \{\{x\}\}, \{\{x\}\} \).

4.100. Let \( a, b \in \mathbb{Z} \). Prove that if \( a \equiv b \) (mod 2) and \( b \equiv a \) (mod 3), then \( a \equiv b \) (mod 6).

4.101. Let \( a, b, c \in \mathbb{R} \). Prove that \( \frac{3}{2}(a^2 + b^2 + c^2 + 1) \geq a(b + 1) + b(c + 1) + c(a + 1) \).

4.102. Prove that if \( a, b \) and \( c \) are positive real numbers, then \( (a + b + c)(\frac{1}{a} + \frac{1}{b} + \frac{1}{c}) \geq 9 \).

4.103. Let \( T = \{1, 2, \ldots, 8\} \).

(a) Determine the elements of the set \( A = \{a \in T : 2^m \equiv a \) (mod 9) for some \( m \in \mathbb{N} \} \).

(b) Determine the elements of the set \( B = \{a \in T : 5^m \equiv a \) (mod 9) for some \( m \in \mathbb{N} \} \).

(c) What property do the sets \( A \) and \( B \) have in (a) and (b)?

4.104. Consider the open sentence \( P(m) : 5m + 1 = a^2 \) for some \( a \in \mathbb{Z} \), where \( m \in \mathbb{N} \). That is, \( P(m) \) is the open sentence: \( 5m + 1 \) is a perfect square.

(a) Determine four distinct solutions \( t \) of \( t^2 \equiv 4 \) (mod 5). For each solution \( t \), determine \( m = \frac{4(t^2-4)}{5} + 3 \) and show that \( P(m) \) is a true statement.

(b) Show that the set \( S = \{t \in \mathbb{Z} : t^2 \equiv 4 \) (mod 5)\} contains infinitely many elements.

(c) Let \( t \) be an element of the set \( S \) in (b). Prove that if \( m = \frac{4(t^2-4)}{5} + 3 \), then \( 5m + 1 \) is a perfect square.

(d) As a consequence of the results established in (a)–(c), what can be concluded about the set \( M = \{m \in \mathbb{N} : 5m + 1 \) is a perfect square\}?

4.105. Let \( a_1, a_2, \ldots, a_n (n \geq 3) \) be \( n \) integers such that \( |a_{i+1} - a_i| \leq 1 \) for \( 1 \leq i \leq n - 1 \). Prove that if \( k \) is any integer that lies strictly between \( a_1 \) and \( a_n \), then there is an integer \( j \) with \( 1 < j < n \) such that \( a_j = k \).
5

Existence and Proof by Contradiction

Thus far, we have been primarily concerned with quantified statements involving universal quantifiers, namely statements of the type ∀x ∈ S, R(x). We now consider problems that involve, either directly or indirectly, quantified statements involving existential quantifiers, that is, statements of the type ∃x ∈ S, R(x).

5.1 COUNTEREXAMPLES

It must certainly come as no surprise that some quantified statements of the type ∀x ∈ S, R(x) are false. We have seen that

\sim (\forall x \in S, R(x)) \equiv \exists x \in S, \sim R(x),

that is, if the statement ∀x ∈ S, R(x) is false, then there exists some element x ∈ S for which R(x) is false. Such an element x is called a counterexample of the (false) statement ∀x ∈ S, R(x). Finding a counterexample verifies that ∀x ∈ S, R(x) is false.

Example 5.1 Consider the statement:

If x ∈ R, then \((x^2 - 1)^2 > 0\). \hspace{1cm} (5.1)

or, equivalently,

For every real number x, \((x^2 - 1)^2 > 0\).

Show that the statement (5.1) is false by exhibiting a counterexample.

Solution For x = 1, \((x^2 - 1)^2 = (1^2 - 1)^2 = 0\). Thus, x = 1 is a counterexample.
Chapter 5  Existence and Proof by Contradiction

It might be noticed that the number \( x = -1 \) is also a counterexample. In fact, \( x = 1 \) and \( x = -1 \) are the only two counterexamples of the statement (5.1), which implies that

\[
\text{If } x \in \mathbb{R} - \{1, -1\}, \text{ then } (x^2 - 1)^2 > 0. \tag{5.2}
\]

is a true statement.

If a statement \( P \) is shown to be false in some manner, then \( P \) is said to be disproved. The counterexample \( x = 1 \) therefore disproves the statement (5.1).

**Example 5.2**  Disprove the statement:

\[
\text{If } x \text{ is a real number, then } \tan^2 x + 1 = \sec^2 x. \tag{5.3}
\]

**Solution**  Since \( \tan x \) and \( \sec x \) are not defined when \( x = \pi/2 \), it follows that \( \tan^2 x + 1 \) and \( \sec^2 x \) have no numerical value when \( x = \pi/2 \) and, consequently, \( \tan^2 x + 1 \) and \( \sec^2 x \) are not equal when \( x = \pi/2 \). That is, \( x = \pi/2 \) is a counterexample to the statement (5.3). ♦

Although \( \tan^2 x + 1 = \sec^2 x \) is a well-known identity from trigonometry and statement (5.3), as presented, is false, the following is true, however:

\[
\text{If } x \text{ is a real number for which } \tan x \text{ and } \sec x \text{ are defined, then } \tan^2 x + 1 = \sec^2 x. \tag{5.4}
\]

Indeed, it is probably statement (5.4) that was intended in Example 5.2, rather than statement (5.3). Since \( \tan x \) and \( \sec x \) are defined for precisely the same real numbers \( x \) (namely, those numbers \( x \) such that \( \cos x \neq 0 \)), we can restate (5.4) as

\[
\text{If } x \in \mathbb{R} - \{n\pi + \frac{\pi}{2} : n \in \mathbb{Z}\}, \text{ then } \tan^2 x + 1 = \sec^2 x.
\]

**Example 5.3**  Disprove the statement:

\[
\text{If } x \in \mathbb{Z}, \text{ then } \frac{x^2 + x}{x^2 - x} = \frac{x + 1}{x - 1}. \tag{5.5}
\]

**Solution**  If \( x = 0 \), then \( x^2 - x = 0 \) and so \( \frac{x^2 + x}{x^2 - x} \) is not defined. On the other hand, if \( x = 0 \), then \( \frac{x + 1}{x - 1} = -1 \); so the expressions \( \frac{x^2 + x}{x^2 - x} \) and \( \frac{x + 1}{x - 1} \) are certainly not equal when \( x = 0 \). Thus, \( x = 0 \) is a counterexample to the statement (5.5).

Since neither \( \frac{x^2 + x}{x^2 - x} \) nor \( \frac{x + 1}{x - 1} \) are defined when \( x = 1 \), it follows that \( x = 1 \) is also a counterexample of statement (5.5). Indeed, \( x = 0 \) and \( x = 1 \) are the only counterexamples of statement (5.5) and so the statement

\[
\text{If } x \in \mathbb{Z} - \{0, 1\}, \text{ then } \frac{x^2 + x}{x^2 - x} = \frac{x + 1}{x - 1}.
\]

is true.

The three preceding examples illustrate the fact that an open sentence \( R(x) \) that is false over some domain \( S \) may very well be true over a subset of \( S \). Therefore, the truth
(or falseness) of a statement \( \forall x \in S, R(x) \) depends not only on the open sentence \( R(x) \) but on its domain as well.

**Example 5.4** Disprove the statement:

For every odd positive integer \( n \), \( 3 \mid (n^2 - 1) \).

**Solution** Since \( 3 \nmid (3^2 - 1) \), it follows that \( n = 3 \) is a counterexample.

Indeed, this example may very well remind you of Result 4.6 where in part (a), it is stated that if \( n \) is an integer such that \( 3 \mid n \), then \( 3 \mid n^2 \); while if \( 3 \nmid n \), then \( 3 \nmid (n^2 - 1) \). So, it is not only expected that \( n = 3 \) is a counterexample but every odd integer \( n \) where \( 3 \mid n \) is a counterexample.

We have seen that a quantified statement of the type

\[
\forall x \in S, \ R(x)
\]

is false if

\[
\exists x \in S, \ \sim R(x)
\]

is true, that is, if there exists some element \( x \in S \) for which \( R(x) \) is false. There will be many instances when \( R(x) \) is an implication \( P(x) \Rightarrow Q(x) \). Therefore, the quantified statement

\[
\forall x \in S, \ P(x) \Rightarrow Q(x)
\]

is false if

\[
\exists x \in S, \ \sim (P(x) \Rightarrow Q(x))
\]

is true. By Theorem 2.25(a), the statement (5.8) can be expressed as

\[
\exists x \in S, \ (P(x) \land (\sim Q(x))).
\]

That is, to show that the statement (5.7) is false, we need to exhibit a counterexample, which, in this case, is an element \( x \in S \) for which \( P(x) \) is true and \( Q(x) \) is false.

**Example 5.5** Disprove the statement:

Let \( n \in \mathbb{Z} \). If \( n^2 + 3n \) is even, then \( n \) is odd.

**Solution** If \( n = 2 \), then \( n^2 + 3n = 2^2 + 3 \cdot 2 = 10 \) is even and \( 2 \) is even. Thus, \( n = 2 \) is a counterexample.

In the preceding example, not only is \( 2 \) a counterexample, every even integer is a counterexample.

**Example 5.6** Disprove the statement:

If \( n \) is an odd integer, then \( n^2 - n \) is odd.

\[(5.9)\]
Chapter 5  Existence and Proof by Contradiction

Solution  For the odd integer \( n = 1 \), the integer \( n^2 - n = 1^2 - 1 = 0 \) is even. Thus, \( n = 1 \) is a counterexample.

Actually, it is not difficult to prove that the statement

If \( n \) is an odd integer, then \( n^2 - n \) is even.

is true. Although it may very well be of interest to know this, to show that statement (5.9) is false requires exhibiting only a single counterexample. It does not require proving some other result. One should know the difference between these two ideas.

Example 5.7  Show that the statement:

Let \( n \in \mathbb{Z} \). If \( 4 \mid (n^2 - 1) \), then \( 4 \mid (n - 1) \).

is false.

Solution  Since \( 4 \mid (3^2 - 1) \) but \( 4 \nmid (3 - 1) \), it follows that \( n = 3 \) is a counterexample.

In Result 4.6(b), it is stated that if \( n \) is an even integer, then \( 4 \mid n^2 \). Also, if \( n \) is odd, then not only \( 4 \mid (n^2 - 1) \) but \( 8 \mid (n^2 - 1) \). So, since \( 4 \mid (n^2 - 1) \), it follows that \( n^2 \) is odd and so \( n \) is odd by Theorem 3.17. Hence, \( 2 \mid (n - 1) \) but this does not mean that \( 4 \mid (n - 1) \).

Example 5.8  Show that the statement

If \( a, b \) and \( c \) are positive integers, then \( a^b \cdot c = (a^b)^c \).

is false.

Solution  Let \( a = 2, \ b = 2 \) and \( c = 3 \). Then \( a^b \cdot c = 2^6 = 256 \), while \( (a^b)^c = (2^2)^3 = 4^3 = 64 \). Since \( 256 \neq 64 \), the positive integers \( a = 2, \ b = 2 \) and \( c = 3 \) constitute a counterexample.

Example 5.9  Show that the statement:

Let \( a \) and \( b \) be nonzero real numbers. If \( x, y \in \mathbb{R}^+ \), then

\[
\frac{a^2}{2b^2}x^2 + \frac{b^2}{2a^2}y^2 > xy.
\]

is false.

Solution  Let \( x = b^2 \) and \( y = a^2 \). Then

\[
\frac{a^2}{2b^2}x^2 + \frac{b^2}{2a^2}y^2 = \frac{a^2b^2}{2} + \frac{a^2b^2}{2} = a^2b^2 = xy.
\]

Thus, \( x = b^2 \) and \( y = a^2 \) is a counterexample and so the inequality is false.
5.2 Proof by Contradiction

Analysis After reading the solution of Example 5.9, the only question that may occur to you is where the counterexample \( x = b^2 \) and \( y = a^2 \) came from. Multiplying the inequality (5.10) by \( 2a^2b^2 \) (which eliminates all fractions) produces the equivalent inequality

\[
a^4x^2 + b^4y^2 > 2a^2b^2xy
\]

and so

\[
a^4x^2 - 2a^2b^2xy + b^4y^2 > 0,
\]

which can be expressed as

\[
(a^2x - b^2y)^2 > 0.
\]

Of course, \((a^2x - b^2y)^2 \geq 0\). Thus, any values of \( x \) and \( y \) for which \( a^2x - b^2y = 0 \) produce a counterexample. Although there are many choices for \( x \) and \( y \), one such choice is \( x = b^2 \) and \( y = a^2 \).

SECTION 5.1 EXERCISES

5.1. Disprove the statement: If \( a \) and \( b \) are any two real numbers, then \( \log(ab) = \log(a) + \log(b) \).
5.2. Disprove the statement: If \( n \in \{0, 1, 2, 3, 4\} \), then \( 2^n + 3^n + n(n-1)(n-2) \) is a prime number.
5.3. Disprove the statement: If \( n \in \{1, 2, 3, 4, 5\} \), then \( 3 \mid (2n^2 + 1) \).
5.4. Disprove the statement: Let \( n \in \mathbb{N} \). If \( \frac{n(n+1)}{2} \) is odd, then \( \frac{(n+1)(n+2)}{2} \) is odd.
5.5. Disprove the statement: For every two positive integers \( a \) and \( b \), \((a + b)^3 = a^3 + 2a^2b + 2ab^2 + b^3 \).
5.6. Let \( a, b \in \mathbb{Z} \). Disprove the statement: If \( ab \) and \((a + b)^2 \) are of opposite parity, then \( a^2b^2 \) and \( a + ab + b \) are of opposite parity.
5.7. (a) In Exercise 4.78, it was stated for every two positive real numbers \( a \) and \( b \) that \( \frac{a}{b} + \frac{b}{a} \geq 2 \). Use this fact to show that \((a + b)(\frac{a}{b} + \frac{b}{a}) \geq 4 \).
(b) If \( a = b \) in the inequality in (a), then this becomes an equality. Is the converse true? That is, if \( a \) and \( b \) are positive real numbers such that \((a + b)(\frac{a}{b} + \frac{b}{a}) = 4 \), does \( a = b \)?
5.8. In Exercise 5.7 it is stated that \((a + b)(\frac{a}{b} + \frac{b}{a}) \geq 4 \) for every two positive real numbers \( a \) and \( b \). Does it therefore follow that \((c^2 + d^2)(\frac{c}{d} + \frac{d}{c}) \geq 4^2 \) for every two positive real numbers \( c \) and \( d \)?
5.9. Disprove the statement: For every positive integer \( x \) and every integer \( n \geq 2 \), the equation \( x^n + (x + 1)^n = (x + 2)^n \) has no solution.
5.10. Disprove the statement: For every three positive integers \( a, b, c \), two of the integers \( ab, ac, bc \) are of the same parity and two of the integers \( ab, ac, bc \) are of opposite parity.
5.11. Disprove the statement: If \( n_1, n_2 \) and \( n_3 \) are three distinct positive integers, then \( 3 \mid (2^{n_1} + 2^{n_2} + 2^{n_3}) \).

5.2 PROOF BY CONTRADICTION

Suppose, as usual, that we would like to show that a certain mathematical statement \( R \) is true. If \( R \) is expressed as the quantified statement \( \forall x \in S, \ P(x) \Rightarrow Q(x) \), then we have already introduced two proof techniques, namely direct proof and proof by contrapositive, that could be used to establish the truth of \( R \). We now introduce a third method that
Existence and Proof by Contradiction

can be used to establish the truth of \( R \), regardless of whether \( R \) is expressed in terms of an implication.

Suppose that we assume \( R \) is a false statement and, from this assumption, we are able to arrive at or deduce a statement that contradicts some assumption we made in the proof or some known fact. (The known fact might be a definition, an axiom or a theorem.) If we denote this assumption or known fact by \( P \), then what we have deduced is \( \sim P \) and have thus produced the contradiction \( C : P \land (\sim P) \). We have therefore established the truth of the implication

\[
(\sim R) \Rightarrow C.
\]

However, because \( (\sim R) \Rightarrow C \) is true and \( C \) is false, it follows that \( \sim R \) is false and so \( R \) is true, as desired. This technique is called **proof by contradiction**.

If \( R \) is the quantified statement \( \forall x \in S, \ P(x) \Rightarrow Q(x) \), then a proof by contradiction of this statement consists of verifying the implication

\[
\sim (\forall x \in S, \ P(x) \Rightarrow Q(x)) \Rightarrow C
\]

for some contradiction \( C \). However, since

\[
\sim (\forall x \in S, \ P(x) \Rightarrow Q(x)) \equiv \exists x \in S, \sim (P(x) \Rightarrow Q(x))
\equiv \exists x \in S, \ (P(x) \land (\sim Q(x))),
\]

it follows that a proof by contradiction of \( \forall x \in S, \ P(x) \Rightarrow Q(x) \) would begin by assuming the existence of some element \( x \in S \) such that \( P(x) \) is true and \( Q(x) \) is false. That is, a proof by contradiction of \( \forall x \in S, \ P(x) \Rightarrow Q(x) \) begins by assuming the existence of a counterexample of this quantified statement. Often the reader is alerted that a proof by contradiction is being used by saying (or writing)

```
Suppose that \( R \) is false.
```

or

```
Assume, to the contrary, that \( R \) is false.
```

Therefore, if \( R \) is the quantified statement \( \forall x \in S, \ P(x) \Rightarrow Q(x) \), then a proof by contradiction might begin with:

```
Assume, to the contrary, that there exists some element \( x \in S \) for which \( P(x) \) is true and \( Q(x) \) is false.
```

(or something along these lines). The remainder of the proof then consists of showing that this assumption leads to a contradiction.

Let’s now look at some examples of proof by contradiction. We begin by establishing a fact about positive real numbers.

**Result to Prove** There is no smallest positive real number.

**Proof Strategy** In a proof by contradiction, we begin by assuming that the statement is false and attempt to show that this leads us to a contradiction. Hence, we begin by assuming that there is a smallest positive real number. It is useful to represent this number by a symbol, say \( r \). Our goal is to produce a contradiction. How do we go about doing this? Of course,
5.2 Proof by Contradiction

if we could think of a positive real number that is less than \( r \), then this would give us a contradiction.

Result 5.10 There is no smallest positive real number.

**Proof** Assume, to the contrary, that there is a smallest positive real number, say \( r \). Since \( 0 < r/2 < r \), it follows that \( r/2 \) is a positive real number that is smaller than \( r \). This, however, is a contradiction.

**PROOF ANALYSIS** The contradiction referred to in the proof of Result 5.10 is the statement: \( r \) is the smallest positive real number and \( r/2 \) is a positive real number that is less than \( r \). This statement is certainly false. We have assumed that the reader understands what contradiction has been obtained. If we think that the reader may not see this, then, of course, we should specifically state (in the proof) what the contradiction is.

There is another point concerning Result 5.10 that should be made. This result states that “there is no smallest positive real number.” This is a negative-sounding result. In the vast majority of cases, proofs of negative-sounding results are given by contradiction. Thus, the proof technique used in Result 5.10 is not unexpected.

Let’s consider two additional examples.

Result 5.11 No odd integer can be expressed as the sum of three even integers.

**Proof** Assume, to the contrary, that there exists an odd integer \( n \) that can be expressed as the sum of three even integers \( x, y \) and \( z \). Then \( x = 2a, y = 2b \) and \( z = 2c \) with \( a, b, c \in \mathbb{Z} \). Therefore,

\[
n = x + y + z = 2a + 2b + 2c = 2(a + b + c).
\]

Since \( a + b + c \) is an integer, \( n \) is even. This is a contradiction.

**PROOF ANALYSIS** Consider the statement:

\( R \): No odd integer can be expressed as the sum of three even integers.

Obviously, Result 5.11 states that \( R \) is a true statement. In order to give a proof by contradiction of Result 5.11, we attempted to prove an implication of the type \( (\sim R) \Rightarrow C \) for some contradiction \( C \). The negation \( \sim R \) is

\( \sim R \): There exists an odd integer that can be expressed as the sum of three even integers.

The proof we gave of Result 5.11 began by assuming the truth of \( \sim R \). We introduced symbols for the four integers involved to make it easier to explain the proof. Eventually, we were able to show that \( n \) is an even integer. On the other hand, we knew that \( n \) is odd. Hence, \( n \) was both even and odd. This was our contradiction \( C \).

In the two examples of proof by contradiction that we have given, neither statement to be proved is expressed as an implication. For our next example, we consider an implication.
Chapter 5  Existence and Proof by Contradiction

Result 5.12  If $a$ is an even integer and $b$ is an odd integer, then $4 \nmid (a^2 + 2b^2)$.

**Proof**  Assume, to the contrary, that there exist an even integer $a$ and an odd integer $b$ such that $4 \mid (a^2 + 2b^2)$. Thus, $a = 2x$, $b = 2y + 1$ and $a^2 + 2b^2 = 4z$ for some integers $x$, $y$ and $z$. Hence,

$$a^2 + 2b^2 = (2x)^2 + 2(2y + 1)^2 = 4z.$$  

Simplifying, we obtain $4x^2 + 8y^2 + 8y + 2 = 4z$ or, equivalently,

$$2 = 4z - 4x^2 - 8y^2 - 8y = 4(z - x^2 - 2y^2 - 2y).$$

Since $z - x^2 - 2y^2 - 2y$ is an integer, $4 \nmid 2$, which is impossible.  

**Proof Analysis**  Let $S$ be the set of even integers and $T$ the set of odd integers. In Result 5.12, our goal was to prove that

$$\forall a \in S, \forall b \in T, ~ P(a, b).$$  \hspace{1cm} (5.11)

is true, where

$$P(a, b): 4 \nmid (a^2 + 2b^2).$$

Since we were attempting to prove (5.11) by contradiction, we wanted to establish the truth of

$$\neg (\forall a \in S, \forall b \in T, ~ P(a, b)) \Rightarrow C$$

for some contradiction $C$ or, equivalently, the truth of

$$\exists a \in S, \exists b \in T, ~ (\neg P(a, b)) \Rightarrow C.$$

Hence, we began by assuming that there exist an even integer $a$ and an odd integer $b$ such that $4 \mid (a^2 + 2b^2)$. We eventually deduced that $4 \mid 2$, which is a false statement and thereby produced a desired contradiction.

Using some facts we discussed earlier, we could have given a direct proof of Result 5.12. Once we wrote $a = 2x$ and $b = 2y + 1$, we have

$$a^2 + 2b^2 = (2x)^2 + 2(2y + 1)^2 = 4x^2 + 8y^2 + 8y + 2$$

$$= 4(x^2 + 2y^2 + 2y).$$

Hence, we have expressed $a^2 + 2b^2$ as $4q + 2$, where $q = x^2 + 2y^2 + 2y$. That is, dividing $a^2 + 2b^2$ by 4 results in a remainder of 2 and so $4 \nmid (a^2 + 2b^2)$. At this stage, however, a proof by contradiction of Result 5.12 is probably preferred, in order to both practice and understand this proof technique.

Let’s consider two other negative-sounding results.

Result 5.13  The integer 100 cannot be written as the sum of three integers, an odd number of which are odd.

**Proof**  Assume, to the contrary, that 100 can be written as the sum of three integers $a$, $b$ and $c$, an odd number of which are odd. We consider two cases.
5.2 Proof by Contradiction

Case 1. Exactly one of \(a, b\) and \(c\) is odd, say \(a\). Then \(a = 2x + 1\), \(b = 2y\) and \(c = 2z\), where \(x, y, z \in \mathbb{Z}\). So,

\[
100 = a + b + c = (2x + 1) + 2y + 2z = 2(x + y + z) + 1.
\]

Since \(x + y + z \in \mathbb{Z}\), the integer 100 is odd, producing a contradiction.

Case 2. All of \(a, b\) and \(c\) are odd. Then \(a = 2x + 1\), \(b = 2y + 1\) and \(c = 2z + 1\), where \(x, y, z \in \mathbb{Z}\). So,

\[
100 = a + b + c = (2x + 1) + (2y + 1) + (2z + 1) = 2(x + y + z + 1) + 1.
\]

Since \(x + y + z + 1 \in \mathbb{Z}\), the integer 100 is odd, again a contradiction. $\blacksquare$

**PROOF ANALYSIS**

Observe that the proof of Result 5.13 begins by assuming that 100 can be written as the sum of three integers, an odd number of which are odd (as expected). However, by introducing symbols for these integers, namely \(a, b\) and \(c\), this made for an easier and clearer proof.

**Result 5.14**

For every integer \(m\) such that \(2 \mid m\) and \(4 \nmid m\), there exist no integers \(x\) and \(y\) for which \(x^2 + 3y^2 = m\).

**Proof**

Assume, to the contrary, that there exist an integer \(m\) such that \(2 \mid m\) and \(4 \nmid m\) and integers \(x\) and \(y\) for which \(x^2 + 3y^2 = m\). Since \(2 \mid m\), it follows that \(m\) is even. By Theorem 3.16, \(x^2\) and \(3y^2\) are of the same parity. We consider two cases.

**Case 1.** \(x^2\) and \(3y^2\) are even. Since \(3y^2\) is even and \(3\) is odd, it follows by Theorem 3.17 that \(y^2\) is even. Because \(x^2\) and \(y^2\) are both even, we have by Theorem 3.12 that \(x\) and \(y\) are even. Thus, \(x = 2a\) and \(y = 2b\), where \(a, b \in \mathbb{Z}\). Therefore,

\[
x^2 + 3y^2 = (2a)^2 + 3(2b)^2 = 4a^2 + 12b^2 = 4(a^2 + 3b^2) = m.
\]

Since \(a^2 + 3b^2 \in \mathbb{Z}\), it follows that \(4 \mid m\), producing a contradiction.

**Case 2.** \(x^2\) and \(3y^2\) are odd. Since \(3y^2\) is odd and \(3\) is odd, it follows by (the contrapositive formulation of) Theorem 3.17 that \(y^2\) is odd. By (the contrapositive formulation of) Theorem 3.12, \(x\) and \(y\) are both odd. Then \(x = 2a + 1\) and \(y = 2b + 1\), where \(a, b \in \mathbb{Z}\). Thus,

\[
x^2 + 3y^2 = (2a + 1)^2 + 3(2b + 1)^2 = (4a^2 + 4a + 1) + 3(4b^2 + 4b + 1)
= 4a^2 + 4a + 12b^2 + 12b + 4 = 4(a^2 + a + 3b^2 + 3b + 1) = m.
\]

Since \(a^2 + a + 3b^2 + 3b + 1 \in \mathbb{Z}\), it follows that \(4 \mid m\), producing a contradiction. $\blacksquare$

The next result concerns irrational numbers. Recall that a real number is rational if it can be expressed as \(m/n\) for some \(m, n \in \mathbb{Z}\), where \(n \neq 0\). Since “irrational” means “not rational,” it is not surprising that proof by contradiction is the proof technique we will use.

**Result 5.15**

The sum of a rational number and an irrational number is irrational.
Chapter 5  Existence and Proof by Contradiction

Proof  Assume, to the contrary, that there exist a rational number $x$ and an irrational number $y$ whose sum is a rational number $z$. Thus, $x + y = z$, where $x = a/b$ and $z = c/d$ for some integers $a, b, c, d$ and $b, d \neq 0$. This implies that

$$y = z - x = \frac{c}{d} - \frac{a}{b} = \frac{bc - ad}{bd}.$$  

Since $bc - ad$ and $bd$ are integers and $bd \neq 0$, it follows that $y$ is rational, which is a contradiction. 

Result 5.15 concerns the irrationality of numbers. One of the best known irrational numbers is $\sqrt{2}$. Although we have never verified that this number is irrational, we establish this fact now.

**Theorem to Prove**  The real number $\sqrt{2}$ is irrational.

**PROOF STRATEGY**  In the proof of this result, we will use Theorem 3.12, which states that an integer $x$ is even if and only if $x^2$ is even. Also, in the proof, it will be useful to express a rational number $m/n$, where $m, n \in \mathbb{Z}$ and $n \neq 0$, in lowest terms, which means that $m$ and $n$ contain no common divisor greater than 1.

**Theorem 5.16**  The real number $\sqrt{2}$ is irrational.

**Proof**  Assume, to the contrary, that $\sqrt{2}$ is rational. Then $\sqrt{2} = a/b$, where $a, b \in \mathbb{Z}$ and $b \neq 0$. We may further assume that $a/b$ has been expressed in (or reduced to) lowest terms. Then $2 = a^2/b^2$; so $a^2 = 2b^2$. Since $b^2$ is an integer, $a^2$ is even. By Theorem 3.12, $a$ is even. So, $a = 2c$, where $c \in \mathbb{Z}$. Thus, $(2c)^2 = 2b^2$ and so $4c^2 = 2b^2$. Therefore, $b^2 = 2c^2$. Because $c^2$ is an integer, $b^2$ is even, which implies by Theorem 3.12 that $b$ is even. Since $a$ and $b$ are even, each has 2 as a divisor, which is a contradiction since $a/b$ has been reduced to lowest terms.

We now take a brief diversion from our discussion of proof by contradiction to present a “story” problem.

**The Three Prisoners Problem**  Three prisoners (see Figure 5.1) have been sentenced to long terms in prison, but due to overcrowded conditions, one prisoner must be released.

The warden devises a scheme to determine which prisoner is to be released. He tells the prisoners that he will blindfold them and then paint a red dot or a blue dot on each forehead. After he paints the dots, he will remove the blindfolds and a prisoner should raise his hand if he sees a red dot on at least one of the other two prisoners. The first prisoner to identify the color of the dot on his own forehead will be released. Of course, the prisoners agree to this. (What do they have to lose?)

The warden blindfolds the prisoners, as promised, and then paints a dot on the foreheads of all three prisoners. In fact, he paints a red dot on the foreheads of all three prisoners. He removes the blindfolds and, since each prisoner sees a red dot (indeed two red dots), each prisoner raises his hand. Some time passes when one of the prisoners exclaims, “I know what color my dot is! It’s red!” This prisoner is then released.
Although the story of the three prisoners is over, there is a lingering question: How did this prisoner correctly identify the color of the dot painted on his forehead?

The solution is given next but try to determine the answer for yourself before reading on.

Let’s assume (without loss of generality) that it’s prisoner #1 (see Figure 5.1) who determined that he had a red dot painted on his forehead. How did he come to this conclusion? Perhaps you think he just guessed since he had nothing to lose anyway. But this is not the answer we were looking for.

Prisoner #1 knows that the color of his dot is either red or blue. He thinks, “Assume, to the contrary, that my dot is blue. Then, of course, #2 knows this and he knows that #3 has a red dot. (That’s why #2 raised his hand.) But #2 also knows that #3 raised his hand. So, if my dot is blue, #2 knows his dot is red. Similarly, if my dot is blue, then #3 knows his dot is red. In other words, if my dot is blue, then both #2 and #3 should be able to identify the colors of their dots quite quickly. But time has passed and they haven’t determined the colors of their dots. So, my dot can’t be blue.” Therefore, #1 exclaims, “I know what color my dot is! It’s red!”

What you probably noticed is that the reasoning #1 used to conclude that his dot is red is proof by contradiction. It seems as if there is more to know about prisoner #1. But that’s another story.

SECTION 5.2 EXERCISES

5.12. Prove that there is no largest negative rational number.
5.13. Prove that there is no smallest positive irrational number.
5.14. Prove that 200 cannot be written as the sum of an odd integer and two even integers.
5.15. Use proof by contradiction to prove that if \( a \) and \( b \) are odd integers, then \( 4 \nmid (a^2 + b^2) \).
5.16. Prove that if \( a \geq 2 \) and \( b \) are integers, then \( a \nmid b \) or \( a \nmid (b + 1) \).
5.17. Prove that 1000 cannot be written as the sum of three integers, an even number of which are even.
Chapter 5  Existence and Proof by Contradiction

5.18. Prove that the product of an irrational number and a nonzero rational number is irrational.

5.19. Prove that when an irrational number is divided by a (nonzero) rational number, the resulting number is irrational.

5.20. Let \( a \) be an irrational number and \( r \) a nonzero rational number. Prove that if \( s \) is a real number, then either \( ar + s \) or \( ar - s \) is irrational.

5.21. Prove that \( \sqrt{3} \) is irrational. [Hint: By Result 4.8, for an integer \( a \), \( 3 \mid a^2 \) if and only if \( 3 \mid a \).]

5.22. Prove that \( \sqrt{2} + \sqrt{3} \) is an irrational number.

5.23. (a) Prove that \( \sqrt{6} \) is an irrational number.

(b) Prove that there are infinitely many positive integers \( n \) such that \( \sqrt{n} \) is irrational.

5.24. Let \( S = \{ p + q\sqrt{2} : p, q \in \mathbb{Q} \} \) and \( T = \{ r + s\sqrt{3} : r, s \in \mathbb{Q} \} \). Prove that \( S \cap T = \mathbb{Q} \).

5.25. Prove that there is no integer \( a \) such that \( a \equiv 5 \pmod{14} \) and \( a \equiv 3 \pmod{21} \).

5.26. Prove that there exists no positive integer \( x \) such that \( 2^x < x^2 < 3^x \).

5.27. Prove that there do not exist three distinct positive integers \( a, b \) and \( c \) such that each integer divides the difference of the other two.

5.28. Prove that the sum of the squares of two odd integers cannot be the square of an integer.

5.29. Prove that if \( x \) and \( y \) are positive real numbers, then \( \sqrt{x+y} \neq \sqrt{x} + \sqrt{y} \).

5.30. Prove that there do not exist positive integers \( m \) and \( n \) such that \( m^2 - n^2 = 1 \).

5.31. Let \( m \) be a positive integer of the form \( m = 2s \), where \( s \) is an odd integer. Prove that there do not exist positive integers \( x \) and \( y \) such that \( x^2 - y^2 = m \).

5.32. Prove that there do not exist three distinct real numbers \( a, b \) and \( c \) such that all of the numbers \( a + b + c, \ ab, ac, bc, abc \) are equal.

5.33. Use a proof by contradiction to prove the following. Let \( x, y \in \mathbb{Z} \). If \( 5 \nmid xy \), then \( 5 \nmid x \) and \( 5 \nmid y \).

5.34. Prove that there exist no positive integers \( m \) and \( n \) for which \( m^2 + m + 1 = n^2 \).

5.35. (a) Prove that there is no rational number solution of the equation \( x^2 - 3x + 1 = 0 \).

(b) The problem in (a) should suggest a more general problem. State and outline a proof of this.

5.3 A REVIEW OF THREE PROOF TECHNIQUES

We have seen that we’re often in a situation where we want to prove the truth of a statement \( \forall x \in S, \ P(x) \Rightarrow Q(x) \). You have now been introduced to three proof techniques: direct proof, proof by contrapositive, proof by contradiction. For each of these three techniques, you should be aware of how to start a proof and what your goal should be. You should also know what not to do. Figure 5.2 gives several ways that we might start a proof. Only some of these can lead to a proof, however.

Let’s now compare the three proof techniques with two examples.

Result 5.17  If \( n \) is an even integer, then \( 3n + 7 \) is odd.

Direct Proof  Let \( n \) be an even integer. Then \( n = 2x \) for some integer \( x \). Therefore,

\[
3n + 7 = 3(2x) + 7 = 6x + 7 = 2(3x + 3) + 1.\]

Since \( 3x + 3 \) is an integer, \( 3n + 7 \) is odd.

**Figure 5.2** How to prove (and not to prove): $\forall x \in S, P(x) \Rightarrow Q(x)$

**Proof by Contrapositive**
Assume that $3n + 7$ is even. Then $3n + 7 = 2y$ for some integer $y$. Hence,

$$n = (3n + 7) + (-2n - 7) = 2y - 2n - 7 = 2(y - n - 4) + 1.$$  

Since $y - n - 4$ is an integer, $n$ is odd.

**Proof by Contradiction**
Assume, to the contrary, that there exists an even integer $n$ such that $3n + 7$ is even. Since $n$ is even, $n = 2x$ for some integer $x$. Hence,

$$3n + 7 = 3(2x) + 7 = 6x + 7 = 2(3x + 3) + 1.$$  

Since $3x + 3$ is an integer, $3n + 7$ is odd, which is a contradiction.

Although a direct proof of Result 5.17 is certainly the preferred proof technique in this case, it is useful to compare all three techniques. The following example is more intricate.

**Result 5.18** Let $x$ be a nonzero real number. If $x + \frac{1}{x} < 2$, then $x < 0$.

**Direct Proof** Assume that $x + \frac{1}{x} < 2$. Since $x \neq 0$, we know that $x^2 > 0$. Multiplying both sides of the inequality $x + \frac{1}{x} < 2$ by $x^2$, we obtain $x^2 \left(x + \frac{1}{x}\right) < 2x^2$. Simplifying this inequality,
Chapter 5  Existence and Proof by Contradiction

we have $x^3 + x - 2x^2 < 0$; so,

$$x(x^2 - 2x + 1) = x(x - 1)^2 < 0.$$ 

Since $(x - 1)^2 \geq 0$ and $x(x - 1)^2 \neq 0$, we must have $(x - 1)^2 > 0$. Since $x(x - 1)^2 < 0$ and $(x - 1)^2 > 0$, it follows that $x < 0$, as desired.

Proof Strategy for Proof by Contrapositive

For a proof by contrapositive, we will begin by assuming that $x \geq 0$ and attempt to show that $x + \frac{1}{x} \geq 2$. This inequality can be simplified by multiplying through by $x$, obtaining $x^2 + 1 \geq 2x$. Subtracting $2x$ from both sides, we have $x^2 - 2x + 1 = (x - 1)^2 \geq 0$, which, of course, we know to be true. A proof is suggested then by reversing the order of these steps:

$$x + \frac{1}{x} \geq 2$$

$$x^2 + 1 \geq 2x$$

$$x^2 - 2x + 1 = (x - 1)^2 \geq 0.$$ 

This method is common when dealing with inequalities.

Proof by Contrapositive

Assume that $x \geq 0$. Since $x \neq 0$, it follows that $x > 0$. Because $(x - 1)^2 \geq 0$, we have $(x - 1)^2 = x^2 - 2x + 1 \geq 0$. Adding $2x$ to both sides of this inequality, we obtain $x^2 + 1 \geq 2x$. Dividing both sides of the inequality $x^2 + 1 \geq 2x$ by the positive number $x$, we obtain $x + \frac{1}{x} \geq 2$, as desired.

Proof by Contradiction

Assume, to the contrary, that there exists a nonzero real number $x$ such that $x + \frac{1}{x} < 2$ and $x \geq 0$. Since $x \neq 0$, it follows that $x > 0$. Multiplying both sides of the inequality $x + \frac{1}{x} < 2$ by $x$, we obtain $x^2 + 1 < 2x$. Subtracting $2x$ from both sides, we have $x^2 - 2x + 1 < 0$. It then follows that $(x - 1)^2 < 0$, which is a contradiction.

Many mathematicians feel that if a result can be verified by a direct proof, then this is the proof technique that should be used, as it is normally easier to understand. This is only a general guideline, however; it is not a hard and fast rule.

SECTION 5.3 EXERCISES

5.36. Prove that if $n$ is an odd integer, then $7n - 5$ is even by
   (a) a direct proof, (b) a proof by contrapositive and (c) a proof by contradiction.

5.37. Let $x$ be a positive real number. Prove that if $x - \frac{2}{x} > 1$, then $x > 2$ by
   (a) a direct proof, (b) a proof by contrapositive and (c) a proof by contradiction.

5.38. Let $a, b \in \mathbb{R}$. Prove that if $ab \neq 0$, then $a \neq 0$ by using more than one proof technique.

5.39. Let $x, y \in \mathbb{R}^+$. Prove that if $x \leq y$, then $x^2 \leq y^2$ by
   (a) a direct proof, (b) a proof by contrapositive and (c) a proof by contradiction.
5.40. Prove the following statement using more than one method of proof.
Let \( a, b \in \mathbb{Z} \). If \( a \) is odd and \( a + b \) is even, then \( b \) is odd and \( ab \) is odd.

5.41. Prove the following statement using more than one method of proof.
For every three integers \( a, b \) and \( c \), exactly two of the integers \( ab, ac \) and \( bc \) cannot be odd.

5.4 EXISTENCE PROOFS

In an **existence theorem** the existence of an object (or objects) possessing some specified property or properties is asserted. Typically then, an existence theorem concerning an open sentence \( R(x) \) over a domain \( S \) can be expressed as a quantified statement

\[
\exists x \in S, R(x) : \text{There exists } x \in S \text{ such that } R(x). \tag{5.12}
\]

We have seen that such a statement (5.12) is true provided that \( R(x) \) is true for some \( x \in S \). A proof of an existence theorem is called an **existence proof**. An existence proof may then consist of displaying or constructing an example of such an object or perhaps, with the aid of known results, verifying that such objects must exist without ever producing a single example of the desired type. For example, there are theorems in mathematics that tell us that every polynomial of odd degree with real coefficients has at least one real number as a solution, but we don’t know how to find a real number solution for every such polynomial. Indeed, we quote the famous mathematician David Hilbert, who used the following example in his lectures to illustrate the idea of an existence proof:

*There is at least one student in this class . . . let us name him ‘X’ . . . for whom the following statement is true: No other student in the class has more hairs on his head than X. Which student is it? That we shall never know; but of his existence we can be absolutely certain.*

Let’s now see some examples of existence proofs.

**Result to Prove** There exists an integer whose cube equals its square.

**Proof Strategy** Since this result is only asserting the existence of an integer whose cube equals its square, we have a proof once we can think of an example. The integer 1 has this property. ♦

**Result 5.19** There exists an integer whose cube equals its square.

**Proof** Since \( 1^3 = 1^2 = 1 \), the integer 1 has the desired property.

Suppose that we didn’t notice that the integer 1 satisfied the required condition in the preceding theorem. Then an alternate proof may go something like this: Let \( x \in \mathbb{Z} \) such that \( x^3 = x^2 \). Then \( x^3 - x^2 = 0 \) or \( x^2(x - 1) = 0 \). Thus, there are only two possible integers with this property, namely 1 and 0 and, in fact, both integers have the desired property.

A common error in elementary algebra is to write \((a + b)^2 = a^2 + b^2\). Can this ever be true?

**Result 5.20** There exist real numbers \( a \) and \( b \) such that \((a + b)^2 = a^2 + b^2\).
142 Chapter 5  Existence and Proof by Contradiction

Proof  Let \( a, b \in \mathbb{Z} \) such that \((a + b)^2 = a^2 + b^2\). Then \(a^2 + 2ab + b^2 = a^2 + b^2\), so \(2ab = 0\). Since \(a = 1, b = 0\) is a solution to this equation, we have
\[
(a + b)^2 = (1 + 0)^2 = 1^2 = 1^2 + 0^2 = a^2 + b^2.
\]

The proof presented of Result 5.20 is longer than necessary. We could have written the following proof:

Proof  Let \( a = 1 \) and \( b = 0 \). Then
\[
(a + b)^2 = (1 + 0)^2 = 1^2 = 1^2 + 0^2 = a^2 + b^2.
\]

In the first proof, we actually presented an argument for how we thought of \( a = 1 \) and \( b = 0 \). In a proof, we are not required to explain where we got the idea for the proof, although it may very well be interesting to know this. If we feel that such information might be interesting or valuable, it may be worthwhile to include this in a discussion preceding or following the proof. The first proof we gave of Result 5.20 actually informs us of all real numbers \( a \) and \( b \) for which \((a + b)^2 = a^2 + b^2\), namely, \((a + b)^2 = a^2 + b^2\) if and only if at least one of \( a \) and \( b \) is \( 0 \). This is more than what was requested of us but, nevertheless, it seems interesting.

We saw in Section 5.2 that \( \sqrt{2} \) is irrational. Since \( \sqrt{2} = 2^{1/2} \), it follows that there exist rational numbers \( a \) and \( b \) such that \( a^b \) is irrational, namely \( a = 2 \) and \( b = 1/2 \) have this property. Let’s reverse this question. That is, do there exist irrational numbers \( a \) and \( b \) such that \( a^b \) is rational? Although there are many irrational numbers (in fact, an infinite number), we have only verified that \( \sqrt{2} \) is irrational. (On the other hand, we know from the exercises for this section that \( r + \sqrt{2} \) is irrational for every rational number \( r \) and that both \( r \sqrt{2} \) and \( r/\sqrt{2} \) are irrational for every nonzero rational number \( r \).)

Result to Prove  There exist irrational numbers \( a \) and \( b \) such that \( a^b \) is rational.

PROOF STRATEGY  As we mentioned, there are only certain numbers that we know to be irrational, the simplest being \( \sqrt{2} \). This might suggest considering the (real) number \( \sqrt{2}^{\sqrt{2}} \). If this number is rational, then this answers our question. But perhaps \( \sqrt{2}^{\sqrt{2}} \) is irrational. Then what do we do? This discussion suggests two cases.

Result 5.21  There exist irrational numbers \( a \) and \( b \) such that \( a^b \) is rational.

Proof  Consider the number \( \sqrt{2}^{\sqrt{2}} \). Of course, this number is either rational or irrational. We consider these possibilities separately.

Case 1. \( \sqrt{2}^{\sqrt{2}} \) is rational. Then we can take \( a = b = \sqrt{2} \) and we have the desired result.
Case 2. $\sqrt{2}^\sqrt{2}$ is irrational. In this case, consider the number obtained by raising the (irrational) number $\sqrt{2}$ to the (irrational) power $\sqrt{2}$; that is, consider $a^b$, where $a = \sqrt{2}$ and $b = \sqrt{2}$. Observe that

$$a^b = \left(\sqrt{2}^\sqrt{2}\right)^\sqrt{2} = \sqrt{2}^{\sqrt{2} \cdot \sqrt{2}} = \sqrt{2}^2 = 2,$$

which is rational.

The proof of Theorem 5.21 may seem unsatisfactory to you since we still don’t know two specific irrational numbers $a$ and $b$ such that $a^b$ is rational. We only know that two such numbers exist. We actually do know a bit more, namely either (1) $\sqrt{2}^{\sqrt{2}}$ is rational or (2) $\sqrt{2}^{\sqrt{2}}$ is irrational and $\left(\sqrt{2}^{\sqrt{2}}\right)^\sqrt{2}$ is rational. (Actually it has been proved that $\sqrt{2}^{\sqrt{2}}$ is an irrational number. Hence, there are also irrational numbers of the form of $a^b$, where $a$ and $b$ are both irrational.)

In the next result, we want to show that the equation $x^5 + 2x - 5 = 0$ has a real number solution between $x = 1$ and $x = 2$. It is not easy to find a number that satisfies this equation. Instead, we use a well-known theorem from calculus to show that such a solution exists. You may not remember all the terms used in the following theorem but this is not crucial.

### The Intermediate Value Theorem of Calculus

If $f$ is a function that is continuous on the closed interval $[a, b]$ and $k$ is a number between $f(a)$ and $f(b)$, then there exists a number $c \in (a, b)$ such that $f(c) = k$.

We now give an example to show how this theorem can be used.

**Result 5.22** The equation $x^5 + 2x - 5 = 0$ has a real number solution between $x = 1$ and $x = 2$.

**Proof** Let $f(x) = x^5 + 2x - 5$. Since $f$ is a polynomial function, it is continuous on the set of all real numbers and so $f$ is continuous on the interval $[1, 2]$. Now, $f(1) = -2$ and $f(2) = 31$. Since 0 is between $f(1)$ and $f(2)$, it follows by the Intermediate Value Theorem of Calculus that there is a number $c$ between 1 and 2 such that $f(c) = c^5 + 2c - 5 = 0$. Hence, $c$ is a solution.

As we just saw, the equation $x^5 + 2x - 5 = 0$ has a real number solution between $x = 1$ and $x = 2$. Actually, the equation $x^5 + 2x - 5 = 0$ has exactly one real number solution between $x = 1$ and $x = 2$. This brings up the topic of uniqueness. An element belonging to some prescribed set $A$ and possessing a certain property $P$ is **unique** if it is the only element of $A$ having property $P$. Typically, to prove that only one element of $A$ has property $P$, we proceed in one of two ways:

1. We assume that $a$ and $b$ are elements of $A$ possessing property $P$ and show that $a = b$.
2. We assume that $a$ and $b$ are distinct elements of $A$ possessing property $P$ and show that $a = b$. 
Although (1) results in a direct proof and (2) results in a proof by contradiction, it is often the case that either proof technique can be used.

As an illustration, we return to Result 5.22 and show, in fact, that the equation $x^5 + 2x - 5 = 0$ has a unique real number solution between $x = 1$ and $x = 2$.

**Result 5.23** The equation $x^5 + 2x - 5 = 0$ has a unique real number solution between $x = 1$ and $x = 2$.

**Proof** Assume, to the contrary, that the equation $x^5 + 2x - 5 = 0$ has two distinct real number solutions $a$ and $b$ between $x = 1$ and $x = 2$. We may assume that $a < b$. Since $1 < a < b < 2$, it follows that $a^5 + 2a - 5 < b^5 + 2b - 5$. On the other hand, $a^5 + 2a - 5 = 0$ and $b^5 + 2b - 5 = 0$. Thus,

$$0 = a^5 + 2a - 5 < b^5 + 2b - 5 = 0,$$

which produces a contradiction. ■

Actually, we could have omitted Result 5.22 altogether and replaced it by Result 5.23 only (renumbering this result by Result 5.22), including the proofs of both Results 5.22 and 5.23.

We now present another result concerning uniqueness.

**Result to Prove** For an irrational number $r$, let

$$S = \{sr + t : s, t \in \mathbb{Q}\}.$$

For every $x \in S$, there exist unique rational numbers $a$ and $b$ such that $x = ar + b$.

**Proof Strategy** To verify that $a$ and $b$ are unique, we assume that $x$ can be expressed in two ways, say as $ar + b$ and $cr + d$, where $a, b, c, d \in \mathbb{Q}$, and then show that $a = c$ and $b = d$. Hence, $ar + b = cr + d$. If $a \neq c$, then we can show that $r$ is a rational number, producing a contradiction. Thus, $a = c$. Subtracting $ar$ from both sides of $ar + b = cr + d$, we obtain $b = d$ as well. ♦

We now give a complete proof.

**Result 5.24** For an irrational number $r$, let

$$S = \{sr + t : s, t \in \mathbb{Q}\}.$$

For every $x \in S$, there exist unique rational numbers $a$ and $b$ such that $x = ar + b$.

**Proof** Let $x \in S$ and suppose that $x = ar + b$ and $x = cr + d$, where $a, b, c, d \in \mathbb{Q}$. Then $ar + b = cr + d$. If $a \neq c$, then $(a - c)r = d - b$ and so

$$r = \frac{d - b}{a - c}.$$

Since $\frac{d - b}{a - c}$ is a rational number, this is impossible. So, $a = c$. Subtracting $ar = cr$ from both sides of $ar + b = cr + d$, we obtain $b = d$. ■
Example 5.25

(a) Show that the equation $6x^3 + x^2 - 2x = 0$ has a root in the interval $[-1, 1]$.

(b) Does this equation have a unique root in the interval $[-1, 1]$?

Solution

(a) By inspection, we can see that $x = 0$ is a root of the equation.

(b) Observe that

$$6x^3 + x^2 - 2x = x(6x^2 + x - 2) = x(3x + 2)(2x - 1) = 0.$$ 

Thus, $x = -2/3$ and $x = 1/2$ are also roots of the equation $6x^3 + x^2 - 2x = 0$ and so this equation does not have a unique root in the interval $[-1, 1]$.

We consider a result of a somewhat different nature.

Result to Prove

For every integer $n \geq 7$, there exist positive integers $a$ and $b$ such that $n = 2a + 3b$.

Proof Strategy

First, notice that we can write $7 = 2 \cdot 2 + 3 \cdot 1$, $8 = 2 \cdot 1 + 3 \cdot 2$ and $9 = 2 \cdot 3 + 3 \cdot 1$. So, the result is certainly true for $n = 7, 8, 9$. On the other hand, there is no pair $a, b$ of positive integers such that $6 = 2a + 3b$. Of course, this observation only shows that we cannot replace $n \geq 7$ by $n \geq 6$.

Suppose that $n$ is an integer such that $n \geq 7$. We could bring the integer 2 into the discussion by observing that we can write $n = 2q$ or $n = 2q + 1$, where $q \in \mathbb{Z}$. Actually, if $n = 2q$, then $q \geq 4$ since $n \geq 7$; while if $n = 2q + 1$, then $q \geq 3$ since $n \geq 7$. This is a useful observation.

Result 5.26

For every integer $n \geq 7$, there exist positive integers $a$ and $b$ such that $n = 2a + 3b$.

Proof

Let $n$ be an integer such that $n \geq 7$. Since $n$ is even or odd, either $n = 2q$ or $n = 2q + 1$ for some integer $q$. We consider these two cases.

Case 1. $n = 2q$. Since $n \geq 7$, it follows that $q \geq 4$. Thus,

$$n = 2q = 2(q - 3) + 6 = 2(q - 3) + 3 \cdot 2.$$ 

Since $q \geq 4$, it follows that $q - 3 \in \mathbb{N}$.

Case 2. $n = 2q + 1$. Since $n \geq 7$, it follows that $q \geq 3$. Thus,

$$n = 2q + 1 = 2(q - 1) + 2 + 1 = 2(q - 1) + 3 \cdot 1.$$ 

Since $q \geq 3$, it follows that $q - 1 \in \mathbb{N}$.

SECTION 5.4 EXERCISES

5.42. Show that there exist a rational number $a$ and an irrational number $b$ such that $a^b$ is rational.

5.43. Show that there exist a rational number $a$ and an irrational number $b$ such that $a^b$ is irrational.

5.44. Show that there exist two distinct irrational numbers $a$ and $b$ such that $a^b$ is rational.

5.45. Show that there exist no nonzero real numbers $a$ and $b$ such that $\sqrt[3]{a^2 + b^2} = \sqrt[3]{a^3 + b^3}$. 
5.46. Prove that there exists a unique real number solution to the equation \( x^3 + x^2 - 1 = 0 \) between \( x = \frac{2}{3} \) and \( x = 1 \).

5.47. Let \( R(x) \) be an open sentence over a domain \( S \). Suppose that \( \forall x \in S, R(x) \) is a false statement and that the set \( T \) of counterexamples is a proper subset of \( S \). Show that there exists a subset \( W \) of \( S \) such that \( \forall x \in W, R(x) \) is true.

5.48. (a) Prove that there exist four distinct positive integers such that each integer divides the sum of the remaining integers.

(b) The problem in (a) should suggest another problem to you. State and solve such a problem.

5.49. Let \( S \) be a set of three integers. For a nonempty subset \( A \) of \( S \), let \( \sigma_A \) be the sum of the elements in \( A \). Prove that there exist two distinct nonempty subsets \( B \) and \( C \) of \( S \) such that \( \sigma_B \equiv \sigma_C \pmod{6} \).

5.50. Prove that the equation \( \cos^2(x) - 4x + \pi = 0 \) has a real number solution in the interval \([0, 4]\). (You may assume that \( \cos^2(x) \) is continuous on \([0, 4]\).)

5.51. Prove for every integer \( n \geq 8 \) that there exist nonnegative integers \( a \) and \( b \) such that \( n = 3a + 5b \).

5.52. Prove for every integer \( n \geq 12 \) that there exist nonnegative integers \( a \) and \( b \) such that \( n = 3a + 7b \).

5.53. Prove that there exists a set \( S \) of four distinct primes such that the sum of every three elements of \( S \) is also a prime.

5.54. The statement \( \forall n \in \mathbb{N}, P(n) \) is known to be false. Indeed, it is known that there are exactly \( k \) counterexamples, \( k \in \mathbb{N} \), to this statement. Prove that there exists a positive integer \( m \) such that for the set \( S = \{ n \in \mathbb{N} : n \geq m \} \), the statement \( \forall n \in S, P(n) \) is true.

5.5 DISPROVING EXISTENCE STATEMENTS

Let \( R(x) \) be an open sentence where the domain of \( x \) is \( S \). We have already seen that to disprove a quantified statement of the type \( \forall x \in S, R(x) \), it suffices to produce a counterexample (that is, an element \( x \) in \( S \) for which \( R(x) \) is false). However, disproving a quantified statement of the type \( \exists x \in S, R(x) \) requires a totally different approach. Since

\[ \sim (\exists x \in S, R(x)) \iff \forall x \in S, \sim R(x), \]

it follows that the statement \( \exists x \in S, R(x) \) is false if \( R(x) \) is false for every \( x \in S \). Let’s look at some examples of disproving existence statements.

**Example 5.27** Disprove the statement: There exists an odd integer \( n \) such that \( n^2 + 2n + 3 \) is odd.

**Solution** We show that if \( n \) is an odd integer, then \( n^2 + 2n + 3 \) is even. Let \( n \) be an odd integer. Then \( n = 2k + 1 \) for some integer \( k \). Thus,

\[ n^2 + 2n + 3 = (2k + 1)^2 + 2(2k + 1) + 3 = 4k^2 + 4k + 1 + 4k + 2 + 3 = 4k^2 + 8k + 6 = 2(2k^2 + 4k + 3). \]

Since \( 2k^2 + 4k + 3 \) is an integer, \( n^2 + 2n + 3 \) is even.

**Example 5.28** Disprove the statement: There is a real number \( x \) such that \( x^6 + 2x^4 + x^2 + 2 = 0 \).
5.5 Disproving Existence Statements

Solution Let \( x \in \mathbb{R} \). Since \( x^6, x^4 \) and \( x^2 \) are all even powers of the real number \( x \), it follows that \( x^6 \geq 0, x^4 \geq 0 \) and \( x^2 \geq 0 \). Therefore, \( x^6 + 2x^4 + x^2 + 2 \geq 0 + 0 + 0 + 2 = 2 \) and so \( x^6 + 2x^4 + x^2 + 2 \neq 0 \). Hence, the equation \( x^6 + 2x^4 + x^2 + 2 = 0 \) has no real number solution.

Example 5.29 Disprove the statement: There exists an integer \( n \) such that \( n^3 - n + 1 \) is even.

Solution Let \( n \in \mathbb{Z} \). We consider two cases.

Case 1. \( n \) is even. Then \( n = 2a \), where \( a \in \mathbb{Z} \). So
\[
  n^3 - n + 1 = (2a)^3 - (2a) + 1 = 8a^3 - 2a + 1 = 2(4a^3 - a) + 1.
\]
Since \( 4a^3 - a \) is an integer, \( n^3 - n + 1 \) is odd and so it is not even.

Case 2. \( n \) is odd. Then \( n = 2b + 1 \), where \( b \in \mathbb{Z} \). Hence,
\[
  n^3 - n + 1 = (2b + 1)^3 - (2b + 1) + 1 = 8b^3 + 12b^2 + 6b + 1 - 2b - 1 + 1 = 8b^3 + 12b^2 + 4b + 1 = 2(4b^3 + 6b^2 + 2b) + 1.
\]
Since \( 4b^3 + 6b^2 + 2b \) is an integer, \( n^3 - n + 1 \) is odd and so it is not even.

If we had replaced Example 5.27 by
For every odd integer \( n, n^2 + 2n + 3 \) is even.

replaced Example 5.28 by
For every real number \( x, x^6 + 2x^4 + x^2 + 2 \neq 0 \).

and replaced Example 5.29 by
For every integer \( n, n^3 - n + 1 \) is odd.

then we would have a true statement in each case and the solutions of Examples 5.27–5.29 would become proofs.

We close this section and chapter with an example that uses some of the information we have already encountered.

For \( n = 1, 2, 4, 5 \), there are integer solutions \( x \) and \( y \) to the equation \( x^2 + y^2 = n \) since \( 0^2 + 1^2 = 1, 1^2 + 1^2 = 2, 0^2 + 2^2 = 4 \) and \( 1^2 + 2^2 = 5 \). It is easy to see that there are no integers \( x \) and \( y \) such that \( x^2 + y^2 = 3 \). However, are there rational numbers \( x \) and \( y \) for which \( x^2 + y^2 = 3 \)?

Result to Prove There exist no rational numbers \( x \) and \( y \) such that \( x^2 + y^2 = 3 \).

Proof Strategy The expected approach to use here is to assume, to the contrary, that there are rational numbers \( x \) and \( y \) for which \( x^2 + y^2 = 3 \), say \( x = \frac{a}{b} \) and \( y = \frac{c}{d} \), where \( a, b, c, d \in \mathbb{N} \). After some simplifying, we can arrive at an equation involving integers, one of which is 3. As expected, it would be helpful to make use of divisibility of integers involving 3. Result 4.8 states that \( 3 \mid ab \), where \( a, b \in \mathbb{Z} \), if and only if \( 3 \mid a \) or \( 3 \mid b \); while Result 4.12 states that for each integer \( n \), either \( n^2 \equiv 0 \pmod{3} \) when \( 3 \mid n \) or \( n^2 \equiv 1 \pmod{3} \) when \( 3 \nmid n \).
148  Chapter 5  Existence and Proof by Contradiction

**Result 5.30**  There exist no rational numbers $x$ and $y$ such that $x^2 + y^2 = 3$.

**Proof**  Assume, to the contrary, that there exist rational numbers $x$ and $y$ such that $x^2 + y^2 = 3$. We may assume that $x$ and $y$ are positive rational numbers. Since $x, y \in \mathbb{Q}^+$, it follows that $x = \frac{a}{b}$ and $y = \frac{c}{d}$, where $a, b, c, d \in \mathbb{N}$. Furthermore, we may assume that $\frac{a}{b}$ and $\frac{c}{d}$ are reduced to lowest terms and so no integer greater than 1 divides $a$ and $b$ or divides $c$ and $d$. Therefore, $\frac{a^2}{b^2} + \frac{c^2}{d^2} = 3$ and so

$$a^2d^2 + b^2c^2 = 3b^2d^2. \quad (5.13)$$

First, suppose that 3 divides none of $a, b, c, d$. Then each of $a^2, b^2, c^2$ and $d^2$ is congruent to 1 modulo 3 and so $a^2d^2 + b^2c^2 \equiv 2 \pmod{3}$. Because $3b^2d^2 \equiv 0 \pmod{3}$, this contradicts (5.13). Hence, 3 divides at least one of $a, b, c, d$.

Assume first that 3 divides one of $a$ and $c$, say $3 \mid a$. Thus, $a = 3p$ where $p \in \mathbb{Z}$. Then

$$a^2d^2 + b^2c^2 = 9p^2d^2 + b^2c^2 = 3b^2d^2$$

and so $3(b^2d^2 - 3p^2d^2) = b^2c^2$. Hence, $3 \mid b^2c^2$ and so $3 \mid bc$ by Result 4.8. Furthermore, $3 \mid b_2$ or $3 \mid c$, again by Result 4.8. Since $3 \mid a$ and $a/b$ has been reduced to lowest terms, $3 \mid c$. Thus, $c = 3q$ for some integer $q$. Hence, $9p^2d^2 + b^2(9q^2) = 3b^2d^2$ and so $9(p^2d^2 + b^2q^2) = 3b^2d^2$. Thus, $3(p^2d^2 + b^2q^2) = b^2d^2$ and so $3 \mid b^2d^2$. By Result 4.8, $3 \mid b$ or $3 \mid d$. Since $3 \mid a$ and $3 \mid c$, and $\frac{a}{b}$ and $\frac{c}{d}$ are reduced to lowest terms, it follows that either $3 \mid b$ or $3 \mid d$ produces a contradiction. Hence, $3 \nmid a$ and $3 \nmid c$, which implies that 3 divides at least one of $b$ and $d$.

We claim that 3 must divide both $b$ and $d$. Assume, to the contrary, that 3 divides exactly one of $b$ and $d$, say $3 \mid b$ and $3 \nmid d$. By Results 4.8 and 4.12, $b^2 \equiv 0 \pmod{3}$ and $d^2 \equiv 1 \pmod{3}$. Since $a^2 \equiv 1 \pmod{3}$ and $c^2 \equiv 1 \pmod{3}$, it follows that $a^2d^2 \equiv 1 \pmod{3}$ and $b^2c^2 \equiv 0 \pmod{3}$. Hence, $a^2d^2 + b^2c^2 \equiv 1 \pmod{3}$. Because $3b^2d^2 \equiv 0 \pmod{3}$, this contradicts (5.13). Therefore, as claimed, $3 \mid b$ and $3 \mid d$.

Let $r \geq 1$ be the greatest power of 3 that divides $b$ and $s \geq 1$ the greatest power of 3 that divides $d$. We may assume that $r \leq s$. Then $b = 3^rp$ and $d = 3^sq$, where $r, s, p, q \in \mathbb{N}$ such that $3 \nmid p$ and $3 \nmid q$. It then follows by (5.13) that

$$a^2d^2 + b^2c^2 = 3^{2r}a^2q^2 + 3^{2r}c^2p^2 = 3^{2r+2s+1}p^2q^2$$

and so

$$3^{2r-2s}a^2q^2 + c^2p^2 = 3^{2s+1}p^2q^2. \quad (5.14)$$

If $s > r$, then

$$c^2p^2 = 3^{2s+1}p^2q^2 - 3^{2r-2s}a^2q^2 = 3[3^{2s}p^2q^2 - 3^{2s-2r-1}a^2q^2].$$

Since $3^{2s}p^2q^2 - 3^{2s-2r-1}a^2q^2$ is an integer, it follows that $3 \mid c^2p^2$. However, since $3 \nmid c$ and $3 \nmid p$, this contradicts Result 4.8. If $r = s$, then

$$a^2q^2 + c^2p^2 = 3^{2s+1}p^2q^2 = 3(3^{2s}p^2q^2).$$

Because $3^{2s}p^2q^2$ is an integer, $3 \mid (a^2q^2 + c^2p^2)$. On the other hand, since $a^2q^2 \equiv 1 \pmod{3}$ and $c^2p^2 \equiv 1 \pmod{3}$, it follows that $a^2q^2 + c^2p^2 \equiv 2 \pmod{3}$ and so $3 \nmid (a^2q^2 + c^2p^2)$, which is a contradiction. \[\blacksquare\]
SECTION 5.5 EXERCISES

5.55. Disprove the statement: There exist odd integers $a$ and $b$ such that $4 \mid (3a^2 + 7b^2)$.

5.56. Disprove the statement: There is a real number $x$ such that $x^6 + x^4 + 1 = 2x^2$.

5.57. Disprove the statement: There is an integer $n$ such that $n^4 + n^3 + n^2 + n$ is odd.

5.58. The integers 1, 2, 3 have the property that each divides the sum of the other two. Indeed, for each positive integer $a$, the integers $a$, $2a$, $3a$ have the property that each divides the sum of the other two. Show that the following statement is false.

There exists an example of three distinct positive integers different from $a$, $2a$, $3a$ for some $a \in \mathbb{N}$ having the property that each divides the sum of the other two.

5.59. The statement $\forall n \in \mathbb{N}, P(n)$ is known to have an infinite number of counterexamples. Disprove the statement: There exists a positive integer $m$ such that $\forall n \in (m, \infty), P(n)$ is true.

5.60. (a) Prove that there exist two distinct primes $p$ and $q$ such that the four integers $pq \pm 2$ and $pq \pm 4$ are all primes.

(b) Disprove the statement: There exist two distinct primes $p$ and $q$ such that the six integers $pq \pm 2$, $pq \pm 4$ and $pq \pm 6$ are all primes.

5.61. Show that the following statement is false.

If $A$ and $B$ are two sets of positive integers with $|A| = |B| = 3$ such that whenever an integer $s$ is the sum of the elements of some subset of $A$, then $s$ is also the sum of the elements of some subset of $B$, then $A = B$.

5.62. (a) Prove that if $a \geq 2$ and $n \geq 1$ are integers such that $a^2 + 1 = 2^n$, then $a$ is odd.

(b) Prove that there are no integers $a \geq 2$ and $n \geq 1$ such that $a^2 + 1 = 2^n$.

5.63. Prove that there do not exist positive integers $a$ and $n$ such that $a^2 + 3 = 3^n$.

5.64. Let $x, y \in \mathbb{R}^+$. Use a proof by contradiction to prove that if $x < y$, then $\sqrt{x} < \sqrt{y}$.

5.65. The king’s daughter had three suitors and couldn’t decide which one to marry. So, the king said to the suitors, “I have three gold crowns and two silver ones. I will put either a gold or silver crown on each of your heads. The suitor who can tell me which crown he has will marry my daughter.” The first suitor looked around and said he could not tell. The second did the same. The third suitor said: “I have a gold crown.” He is correct, but the daughter was puzzled: This suitor was blind. How did he know? (Reference: Ask Marilyn, Parade Magazine, July 6, 2003.)

5.66. Prove that if $a$, $b$, $c$, $d$ are four real numbers, then at most four of the numbers $ab$, $ac$, $ad$, $bc$, $bd$, $cd$ are negative.

5.67. Evaluate the proposed proof of the following result.

Result The number 25 cannot be written as the sum of three integers, an even number of which are odd.

Proof Assume, to the contrary, that 25 can be written as the sum of three integers, an even number of which are odd. Then $25 = x + y + z$, where $x, y, z \in \mathbb{Z}$. We consider two cases.
Chapter 5  Existence and Proof by Contradiction

Case 1. $x$ and $y$ are odd. Then $x = 2a + 1$, $y = 2b + 1$ and $z = 2c$, where $a, b, c \in \mathbb{Z}$. Therefore,

$$25 = x + y + z = (2a + 1) + (2b + 1) + 2c$$
$$= 2a + 2b + 2c + 2 = 2(a + b + c).$$

Since $a + b + c + 1$ is an integer, 25 is even, a contradiction.

Case 2. $x$, $y$ and $z$ are even. Then $x = 2a$, $y = 2b$ and $z = 2c$, where $a, b, c \in \mathbb{Z}$.

Hence,

$$25 = x + y + z = 2a + 2b + 2c = 2(a + b + c).$$

Since $a + b + c$ is an integer, 25 is even, again a contradiction.

5.68. (a) Let $n$ be a positive integer. Show that every integer $m$ with $1 \leq m \leq 2n$ can be expressed as $2^\ell k$, where $\ell$ is a nonnegative integer and $k$ is an odd integer with $1 \leq k < 2n$.

(b) Prove for every positive integer $n$ and every subset $S$ of $\{1, 2, \ldots, 2n\}$ with $|S| = n + 1$ that there exist integers $a, b \in S$ such that $a \not\equiv b$.

5.69. Prove that the sum of all three irrational numbers $\sqrt{2}$, $\sqrt{3}$ and $\sqrt{5}$ is also irrational.

5.70. Let $a_1, a_2, \ldots, a_r$ be odd integers where $a_i > 1$ for $i = 1, 2, \ldots, r$. Prove that if $n = a_1a_2 \cdots a_r + 2$, then $a_i \not\mid n$ for each integer $i$ ($1 \leq i \leq r$).

5.71. Below is given a proof of a result. What result is proved?

**Proof** Let $a, b, c \in \mathbb{Z}$ such that $a^2 + b^2 = c^2$. Assume, to the contrary, that $a, b$ and $c$ are all odd. By (the contrapositive of) Theorem 3.12, $a^2$ and $b^2$ are both odd. Therefore, $a^2 = 2r + 1$ and $b^2 = 2s + 1$ for integers $r$ and $s$. Thus, $a^2 + b^2 = 2r + 2s + 2 = 2(r + s + 1)$. Since $r + s + 1$ is an integer, $a^2 + b^2$ is even. However, $a^2 + b^2 = c^2$ and $c^2$ is odd. This is a contradiction.

5.72. Evaluate the proposed proof of the following result.

**Result** If $x$ is an irrational number and $y$ is a rational number, then $z = x - y$ is irrational.

**Proof** Assume, to the contrary, that $z = a/b$, where $a, b \in \mathbb{Z}$ and $b \neq 0$. Since $\sqrt{2}$ is irrational, we let $x = \sqrt{2}$. Since $y$ is rational, $y = c/d$, where $c, d \in \mathbb{Z}$ and $d \neq 0$. Therefore,

$$\sqrt{2} = x = y + z = \frac{c}{d} + \frac{a}{b} = \frac{ad + bc}{bd}.$$

Since $ad + bc$ and $bd$ are integers, where $bd \neq 0$, it follows that $\sqrt{2}$ is rational, producing a contradiction.

5.73. Prove that there exist four distinct real numbers $a, b, c, d$ such that exactly four of the numbers $ab, ac, ad, bc, bd, cd$ are irrational.

5.74. Below is given a proof of a result. What result is proved?

**Proof** Let $a \equiv 2$ (mod 4) and $b \equiv 1$ (mod 4) and assume, to the contrary, that $4 \mid (a^2 + 2b)$. Since $a \equiv 2$ (mod 4) and $b \equiv 1$ (mod 4), it follows that $a = 4r + 2$ and $b = 4s + 1$, where $r, s \in \mathbb{Z}$. Therefore,

$$a^2 + 2b = (4r + 2)^2 + 2(4s + 1) = (16r^2 + 16r + 4) + (8s + 2)$$
$$= 16r^2 + 16r + 8s + 6.$$
Since $4 \mid (a^2 + 2b)$, we have $a^2 + 2b = 4t$, where $t \in \mathbb{Z}$. So, 

$16r^2 + 16r + 8s + 6 = 4t$ and 

$6 = 4t - 16r^2 - 16r - 8s = 4(t - 4r^2 - 4r - 2s)$. 

Since $t - 4r^2 - 4r - 2s$ is an integer, $4 \mid 6$, which is a contradiction. 

5.75. Prove that there do not exist real numbers $a$ and $b$ in the open interval $(0, 1)$ such that 

$4a(1 - b) > 1$ and $4b(1 - a) > 1$. 
6

Mathematical Induction

We have now seen three proof techniques that can be used to prove that a quantified statement \( \forall x \in S, P(x) \) is true: direct proof, proof by contrapositive, proof by contradiction. For certain sets \( S \), however, there is another possible method of proof: mathematical induction.

6.1 THE PRINCIPLE OF MATHEMATICAL INDUCTION

Let \( A \) be a nonempty set of real numbers. A number \( m \in A \) is called a least element (or a minimum or smallest element) of \( A \) if \( x \geq m \) for every \( x \in A \). Some nonempty sets of real numbers have a least element; others do not. The set \( \mathbb{N} \) has a smallest element, namely 1, while \( \mathbb{Z} \) has no least element. The closed interval \([2, 5]\) has the minimum element 2 but the open interval \((2, 5)\) has no minimum element. The set

\[
A = \left\{ \frac{1}{n} : n \in \mathbb{N} \right\}
\]

also has no least element.

If a nonempty set \( A \) of real numbers has a least element, then this element is necessarily unique. We will verify this fact. Recall that when attempting to prove that an element possessing a certain property is unique, it is customary to assume that there are two elements with this property. We then show that these elements are equal, implying that there is exactly one such element.

**Theorem 6.1** If a set \( A \) of real numbers has a least element, then \( A \) has a unique least element.

**Proof** Let \( m_1 \) and \( m_2 \) be least elements of \( A \). Since \( m_1 \) is a least element, \( m_2 \geq m_1 \). Also, since \( m_2 \) is a least element, \( m_1 \geq m_2 \). Therefore, \( m_1 = m_2 \).

The proof we gave of Theorem 6.1 is a direct proof. Suppose that we had replaced the first sentence of this proof by

Assume, to the contrary, that \( A \) contains distinct least elements \( m_1 \) and \( m_2 \).
6.1 The Principle of Mathematical Induction

If the remainder of the proof of Theorem 6.1 were the same except for adding a concluding sentence that we have a contradiction, then this too would be a proof of Theorem 6.1. That is, with a small change, the proof technique used to verify Theorem 6.1 can be transformed from a direct proof to a proof by contradiction.

There is a property possessed by some sets of real numbers that will be of great interest to us here. A nonempty set $S$ of real numbers is said to be well-ordered if every nonempty subset of $S$ has a least element. Let $S = \{-7, -1, 2\}$. The nonempty subsets of $S$ are

$$\{-7, -1, 2\}, \{-7, -1\}, \{-7, 2\}, \{-1, 2\}, \{-7\}, \{-1\}, \{2\}.$$ 

Since each of these subsets has a least element, $S$ is well-ordered. Indeed, it should be clear that every nonempty finite set of real numbers is well-ordered. (See Exercise 6.20.) The open interval $(0, 1)$ is not well-ordered, since, for example, $(0, 1)$ itself has no least element. The closed interval $[0, 1]$ has the least element $0$; however, $[0, 1]$ is not well-ordered since the open interval $(0, 1)$ is a (nonempty) subset of $[0, 1]$ without a least element. Because none of the sets $\mathbb{Z}, \mathbb{Q}$ and $\mathbb{R}$ has a least element, none of these sets is well-ordered. Hence, having a least element is a necessary condition for a nonempty set to be well-ordered but it is not sufficient.

Although it may appear evident that the set $\mathbb{N}$ of positive integers is well-ordered, this statement cannot be proved from the properties of positive integers that we have used and derived thus far. Consequently, this statement is accepted as an axiom, which we state below.

The set $\mathbb{N}$ of positive integers is well-ordered.

A consequence of the Well-Ordering Principle is another principle, which serves as the foundation for another and important proof technique.

**Theorem 6.2** (The Principle of Mathematical Induction) For each positive integer $n$, let $P(n)$ be a statement. If

1. $P(1)$ is true and
2. the implication

   If $P(k)$, then $P(k + 1)$.

is true for every positive integer $k$,

then $P(n)$ is true for every positive integer $n$.

**Proof** Assume, to the contrary, that the theorem is false. Then conditions (1) and (2) are satisfied but there exist some positive integers $n$ for which $P(n)$ is a false statement. Let $S = \{n \in \mathbb{N} : P(n) \text{ is false}\}$.

Since $S$ is a nonempty subset of $\mathbb{N}$, it follows by the Well-Ordering Principle that $S$ contains a least element $s$. Since $P(1)$ is true, $1 \notin S$. Thus, $s \geq 2$ and $s - 1 \in \mathbb{N}$. Therefore, $s - 1 \notin S$ and so $P(s - 1)$ is a true statement. By condition (2), $P(s)$ is also true and so $s \notin S$. This, however, contradicts our assumption that $s \in S$. 

$\blacksquare$
Chapter 6 Mathematical Induction

The Principle of Mathematical Induction is stated more symbolically below.

The Principle of Mathematical Induction

For each positive integer \( n \), let \( P(n) \) be a statement. If

1. \( P(1) \) is true and
2. \( \forall k \in \mathbb{N}, \ P(k) \Rightarrow P(k+1) \) is true,

then \( \forall n \in \mathbb{N}, \ P(n) \) is true.

As a consequence of the Principle of Mathematical Induction, the quantified statement \( \forall n \in \mathbb{N}, \ P(n) \) can be proved to be true if

1. we can show that the statement \( P(1) \) is true and
2. we can establish the truth of the implication

\[ \text{If } P(k), \text{ then } P(k+1). \]

for every positive integer \( k \).

A proof using the Principle of Mathematical Induction is called an induction proof or a proof by induction. The verification of the truth of \( P(1) \) in an induction proof is called the base step, basis step or the anchor of the induction. In the implication

\[ \text{If } P(k), \text{ then } P(k+1). \]

for an arbitrary positive integer \( k \), the statement \( P(k) \) is called the inductive (or induction) hypothesis. Often we use a direct proof to verify

\[ \forall k \in \mathbb{N}, \ P(k) \Rightarrow P(k+1), \]

although any proof technique is acceptable. That is, we typically assume that the inductive hypothesis \( P(k) \) is true for an arbitrary positive integer \( k \) and attempt to show that \( P(k+1) \) is true. Establishing the truth of (6.1) is called the inductive step in the induction proof.

We illustrate this proof technique by showing that the sum of the first \( n \) positive integers is given by \( n(n+1)/2 \) for every positive integer \( n \), that is,

\[ 1 + 2 + 3 + \cdots + n = \frac{n(n+1)}{2}. \]

Result 6.3 Let

\[ P(n) : 1 + 2 + 3 + \cdots + n = \frac{n(n+1)}{2} \]

where \( n \in \mathbb{N} \). Then \( P(n) \) is true for every positive integer \( n \).

Proof We employ induction. Since \( 1 = (1 \cdot 2)/2 \), the statement \( P(1) \) is true. Assume that \( P(k) \) is true for an arbitrary positive integer \( k \), that is, assume that

\[ 1 + 2 + 3 + \cdots + k = \frac{k(k+1)}{2}. \]
6.1 The Principle of Mathematical Induction

We show that $P(k+1)$ is true, that is, we show that

$$1 + 2 + 3 + \cdots + (k+1) = \frac{(k+1)(k+2)}{2}.$$

Thus,

$$1 + 2 + 3 + \cdots + (k+1) = (1 + 2 + 3 + \cdots + k) + (k+1)$$

$$= \frac{k(k+1)}{2} + (k+1) = \frac{k(k+1) + 2(k+1)}{2}$$

$$= \frac{(k+1)(k+2)}{2},$$

as desired.

By the Principle of Mathematical Induction, $P(n)$ is true for every positive integer $n$.

Typically, a statement to be proved by induction is not presented in terms of $P(n)$ or some other symbols. In order to illustrate this, we give an alternative statement and proof of Result 6.3, as it is to be understood what $P(n)$ would represent.

**Result 6.4** For every positive integer $n$,

$$1 + 2 + 3 + \cdots + n = \frac{n(n+1)}{2}.$$

**Proof** We employ induction. Since $1 = (1 \cdot 2)/2$, the statement is true for $n = 1$. Assume that

$$1 + 2 + 3 + \cdots + k = \frac{k(k+1)}{2},$$

where $k$ is a positive integer. We show that

$$1 + 2 + 3 + \cdots + (k+1) = \frac{(k+1)(k+2)}{2}.$$

Thus,

$$1 + 2 + 3 + \cdots + (k+1) = (1 + 2 + 3 + \cdots + k) + (k+1)$$

$$= \frac{k(k+1)}{2} + (k+1) = \frac{k(k+1) + 2(k+1)}{2}$$

$$= \frac{(k+1)(k+2)}{2}.$$

By the Principle of Mathematical Induction,

$$1 + 2 + 3 + \cdots + n = \frac{n(n+1)}{2}$$

for every positive integer $n$. ■
PROOF ANALYSIS

In the proof of Result 6.3 (or of Result 6.4), we began by stating that induction was being used. This alerts the reader of what to expect in the proof. Also, in the proof of the inductive step, it is assumed that

\[1 + 2 + 3 + \cdots + k = \frac{k(k + 1)}{2}\]

for a positive integer \(k\), that is, for an arbitrary positive integer \(k\). We do not assume that

\[1 + 2 + 3 + \cdots + k = \frac{k(k + 1)}{2}\]

for every positive integer \(k\) as this would be assuming what we are attempting to prove in Result 6.3 (and in Result 6.4).

Carl Friedrich Gauss (1777–1855) is considered to be one of the most brilliant mathematicians of all time. The story goes that when he was very young (in grade school in Germany) his teacher gave him and his classmates the supposedly unpleasant task of adding the integers from 1 to 100. He obtained the correct result of 5050 quickly. It is believed that he considered both the sum \(1 + 2 + \cdots + 100\) and its reverse sum \(100 + 99 + \cdots + 1\) and added these to obtain the sum \(101 + 101 + \cdots + 101\), which has 100 terms and so equals 10,100. Since this is twice the required sum, \(1 + 2 + \cdots + 100 = 10100/2 = 5050\). This, of course, can be quite easily generalized to find a formula for \(1 + 2 + 3 + \cdots + n\), where \(n \in \mathbb{N}\). Let

\[S = 1 + 2 + 3 + \cdots + n. \quad (6.2)\]

If we reverse the order of the terms on the right side of (6.2), then we obtain

\[S = n + (n - 1) + (n - 2) + \cdots + 1. \quad (6.3)\]

Adding (6.2) and (6.3), we have

\[2S = (n + 1) + (n + 1) + (n + 1) + \cdots + (n + 1). \quad (6.4)\]

Since there are \(n\) terms on the right side of (6.4), we conclude that \(2S = n(n + 1)\) or \(S = n(n + 1)/2\). Hence,

\[1 + 2 + 3 + \cdots + n = \frac{n(n + 1)}{2}.\]

You might think that the proof of Result 6.3 (and Result 6.4) that we gave by mathematical induction is longer (and more complicated) than the one we just gave and this may very well be true. But, in general, mathematical induction is a technique that can be used to prove a wide range of statements. In this chapter, we will see a variety of statements where mathematical induction is a natural technique used in verifying their truth.

We begin with an example that leads to a problem involving mathematical induction.

Suppose that an \(n \times n\) square \(S\) is composed of \(n^2\) \(1 \times 1\) squares. For all integers \(k\) with \(1 \leq k \leq n\), how many different \(k \times k\) squares does \(S\) contain? (See Figure 6.1 for the case where \(n = 3\).) For \(n = 3\), the square \(S\) contains the \(3 \times 3\) square \(S\) itself, four \(2 \times 2\) squares and nine \(1 \times 1\) squares (see Figure 6.1). Therefore, the number of different squares that \(S\) contains is \(1 + 4 + 9 = 1^2 + 2^2 + 3^2 = 14\).

In order to determine the number of different \(k \times k\) squares in an \(n \times n\) square \(S\), we place \(S\) in the first quadrant of the coordinate plane so that the lower left corner of \(S\)
157

and 
k \leq 1

\sum k = y + \cdots + y + 1 \text{ and so the number of possibilities for } (n, n). (See Figure 6.2.) Then the upper right corner of \( S \) is at the point \((x, y)\), while the upper right corner of \( S^* \) is at \((x + k, y + k)\). Necessarily, \( x \) and \( y \) are nonnegative integers with \( x + k \leq n \) and \( y + k \leq n \) (again see Figure 6.2). Since \( 0 \leq x \leq n - k \) and \( 0 \leq y \leq n - k \), the number of choices for each of \( x \) and \( y \) is \( n - k + 1 \) and so the number of possibilities for \((x, y)\) is \((n - k + 1)^2\). Because \( k \) is any of the integers 1, 2, \ldots, \( n \), the total number of different squares in \( S \) is

\[
\sum_{k=1}^{n} (n - k + 1)^2 = n^2 + (n - 1)^2 + \cdots + 2^2 + 1^2
\]

\[
= 1^2 + 2^2 + \cdots + n^2 = \sum_{k=1}^{n} k^2.
\]

Is there a compact formula for the expression

\[
\sum_{k=1}^{n} k^2 = 1^2 + 2^2 + \cdots + n^2?
\]
Chapter 6  Mathematical Induction

For the problem we are describing, it would be very helpful to know the answer to this question. Since we brought up this question, you might have already guessed that the answer is yes. A formula is given next, along with a proof by induction.

Result 6.5  For every positive integer \( n \),

\[
1^2 + 2^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}.
\]

Proof  We proceed by induction. Since \( 1^2 = (1 \cdot 2 \cdot 3)/6 = 1 \), the statement is true when \( n = 1 \). Assume that

\[
1^2 + 2^2 + \cdots + k^2 = \frac{k(k + 1)(2k + 1)}{6}
\]

for an arbitrary positive integer \( k \). We show that

\[
1^2 + 2^2 + \cdots + (k + 1)^2 = \frac{(k + 1)(k + 2)(2k + 3)}{6}.
\]

Observe that

\[
1^2 + 2^2 + \cdots + (k + 1)^2 = [1^2 + 2^2 + \cdots + k^2] + (k + 1)^2
\]

\[
= \frac{k(k + 1)(2k + 1)}{6} + (k + 1)^2
\]

\[
= \frac{k(k + 1)(2k + 1)}{6} + \frac{6(k + 1)^2}{6}
\]

\[
= \frac{(k + 1)[k(2k + 1) + 6(k + 1)]}{6}
\]

\[
= \frac{(k + 1)(2k^2 + 7k + 6)}{6}
\]

\[
= \frac{(k + 1)(k + 2)(2k + 3)}{6},
\]

as desired.

By the Principle of Mathematical Induction,

\[
1^2 + 2^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}
\]

for every positive integer \( n \).

Strictly speaking, the last sentence in the proof of Result 6.5 is typical of the last sentence of every proof using mathematical induction, for the idea is to show that the hypothesis of the Principle of Mathematical Induction is satisfied and so the conclusion follows. Some therefore omit this final sentence since it is understood that once properties (1) and (2) of Theorem 6.2 are satisfied, we have a proof. For emphasis, we will continue to include this concluding sentence, however.

There is another question that might have occurred to you. We explained why \( 1 + 2 + \cdots + n \) equals \( n(n + 1)/2 \), but how did we know that \( 1^2 + 2^2 + \cdots + n^2 \)
equals \( n(n+1)(2n+1)/6 \)? We can actually show that \( 1^2 + 2^2 + \cdots + n^2 = n(n+1)(2n+1)/6 \) by using the formula \( 1 + 2 + \cdots + n = n(n+1)/2 \). We begin by solving
\[
(k + 1)^3 = k^3 + 3k^2 + 3k + 1
\]
for \( k^2 \). Since \( 3k^2 = (k + 1)^3 - k^3 - 3k - 1 \), it follows that
\[
k^2 = \frac{1}{3}[(k + 1)^3 - k^3] - k - \frac{1}{3}
\]
and so
\[
\sum_{k=1}^{n} k^2 = \frac{1}{3} \left[ \sum_{k=1}^{n} (k + 1)^3 - \sum_{k=1}^{n} k^3 \right] - \sum_{k=1}^{n} k - \frac{1}{3} \sum_{k=1}^{n} 1.
\]
Therefore,
\[
\sum_{k=1}^{n} k^2 = \frac{1}{3} \left( \sum_{k=1}^{n} (k + 1)^3 - \frac{1}{3} \right) - \frac{1}{2} n(n + 1) - \frac{1}{3} n
\]
\[
= \frac{n^3 + 3n^2 + 3n}{3} - \frac{n^2 + n}{2} - \frac{n}{3}
\]
\[
= \frac{2n^3 + 6n^2 + 6n - 3n^2 - 3n - 2n}{6}
\]
\[
= \frac{n(2n^2 + 3n + 1)}{6}
\]
\[
= \frac{n(n + 1)(2n + 1)}{6}.
\]
This is actually an alternative proof that
\[
1^2 + 2^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}
\]
for every positive integer \( n \) but of course this proof depends on knowing that
\[
1 + 2 + 3 + \cdots + n = \frac{n(n+1)}{2}
\]
for every positive integer \( n \).

We have now used mathematical induction to establish the formulas
\[
1 + 2 + \cdots + n = \frac{n(n+1)}{2} \quad (6.5)
\]
and
\[
1^2 + 2^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6} \quad (6.6)
\]
for every positive integer \( n \). We saw that (6.6) gives the number of different squares in an \( n \times n \) square composed of \( n^2 \) \( 1 \times 1 \) squares. Actually, (6.5) gives the number of intervals in an interval of length \( n \) composed of \( n \) intervals of length 1. You can probably guess what \( 1^3 + 2^3 + \cdots + n^3 \) counts. Exercise 6.6 deals with this expression.

We now present a formula for
\[
\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{(n+1)(n+2)}
\]
for every positive integer \( n \).
Chapter 6  Mathematical Induction

Result 6.6  For every positive integer \( n \),
\[
\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \ldots + \frac{1}{(n+1)(n+2)} = \frac{n}{2n+4}.
\]

Proof  We use induction. Since
\[
\frac{1}{2 \cdot 3} = \frac{1}{2 \cdot 1 + 4} = \frac{1}{6},
\]
the formula holds for \( n = 1 \). Assume that
\[
\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \ldots + \frac{1}{(k+1)(k+2)} = \frac{k}{2k+4}
\]
for a positive integer \( k \). We show that
\[
\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \ldots + \frac{1}{(k+2)(k+3)} = \frac{k+1}{2(k+1)+4} = \frac{k+1}{2k+6}.
\]
Observe that
\[
\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \ldots + \frac{1}{(k+2)(k+3)}
\]
\[
= \left[ \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \ldots + \frac{1}{(k+1)(k+2)} \right] + \frac{1}{(k+2)(k+3)}
\]
\[
= \frac{k}{2k+4} + \frac{1}{(k+2)(k+3)} = \frac{k}{2(k+2)} + \frac{1}{(k+2)(k+3)}
\]
\[
= \frac{k(k+3) + 2}{2(k+2)(k+3)} = \frac{k^2 + 3k + 2}{2(k+2)(k+3)}
\]
\[
= \frac{(k+1)(k+2)}{2(k+2)(k+3)} = \frac{k+1}{2(k+3)} = \frac{k+1}{2k+6},
\]
giving us the desired result. By the Principle of Mathematical Induction,
\[
\frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \ldots + \frac{1}{(n+1)(n+2)} = \frac{n}{2n+4}
\]
for every positive integer \( n \).

PROOF ANALYSIS  Each of the examples of mathematical induction proofs that we have seen involves a certain amount of algebra. We’ll need to recall even more algebra soon. Many mistakes in these proofs are due to algebra errors. Therefore, care must be taken. For example, in the proof of Result 6.6, we encountered the sum
\[
\frac{k}{2(k+2)} + \frac{1}{(k+2)(k+3)}.
\]
To add these fractions, we needed to find a common denominator (actually a least common denominator), which is \( 2(k+2)(k+3) \). This was used to obtain the next fraction, that is,
\[
\frac{k}{2(k+2)} + \frac{1}{(k+2)(k+3)} = \frac{k(k+3)}{2(k+2)(k+3)} + \frac{2}{2(k+2)(k+3)} = \frac{k(k+3) + 2}{2(k+2)(k+3)}.
\]
When we expanded and factored the numerator and then cancelled the term $k + 2$, this was actually expected since the final result we were looking for was

$$\frac{k + 1}{2k + 6} = \frac{k + 1}{2(k + 3)},$$

which does not contain $k + 2$ as a factor in the denominator.

**SECTION 6.1 EXERCISES**

6.1. Which of the following sets are well-ordered?

(a) $S = \{ x \in \mathbb{Q} : x \geq -10 \}$
(b) $S = \{-2, -1, 0, 1, 2\}$
(c) $S = \{ x \in \mathbb{Q} : -1 \leq x \leq 1 \}$
(d) $S = \{ p : p \text{ is a prime} \} = \{ 2, 3, 5, 7, 11, 13, 17, \ldots \}$.

6.2. Prove that if $A$ is any well-ordered set of real numbers and $B$ is a nonempty subset of $A$, then $B$ is also well-ordered.

6.3. Prove that every nonempty set of negative integers has a largest element.

6.4. Prove that $1 + 3 + 5 + \cdots + (2n - 1) = n^2$ for every positive integer $n$

(1) by mathematical induction and
(2) by adding $1 + 3 + 5 + \cdots + (2n - 1)$ and $(2n - 1) + (2n - 3) + \cdots + 1$.

6.5. Use mathematical induction to prove that

$$1 + 5 + 9 + \cdots + (4n - 3) = 2n^2 - n$$

for every positive integer $n$.

6.6. (a) We have seen that $1^2 + 2^2 + \cdots + n^2$ is the number of squares in an $n \times n$ square composed of $n^2$ $1 \times 1$ squares. What does $1^3 + 2^3 + 3^3 + \cdots + n^3$ represent geometrically?

(b) Use mathematical induction to prove that $1^3 + 3^3 + 3^3 + \cdots + n^3 = \frac{n^2(n + 1)^2}{4}$ for every positive integer $n$.

6.7. Find another formula suggested by Exercises 6.4 and 6.5 and verify your formula by mathematical induction.

6.8. Find a formula for $1 + 4 + 7 + \cdots + (3n - 2)$ for positive integers $n$ and then verify your formula by mathematical induction.

6.9. Prove that $1 \cdot 3 + 2 \cdot 4 + 3 \cdot 5 + \cdots + n(n + 2) = \frac{n(n+1)(2n+7)}{6}$ for every positive integer $n$.

6.10. Let $r \neq 1$ be a real number. Use induction to prove that $a + ar + ar^2 + \cdots + ar^{n-1} = \frac{a(1-r^n)}{1-r}$ for every positive integer $n$.

6.11. Prove that $\frac{1}{3^4} + \frac{1}{4^4} + \cdots + \frac{1}{(n+2)^4} = \frac{n}{3n+9}$ for every positive integer $n$.

6.12. Consider the open sentence $P(n): 9 + 13 + \cdots + (4n + 5) = \frac{4n^2+14n+1}{2}$, where $n \in \mathbb{N}$.

(a) Verify the implication $P(k) \Rightarrow P(k + 1)$ for an arbitrary positive integer $k$.

(b) Is $\forall n \in \mathbb{N}, P(n)$ true?
Chapter 6  Mathematical Induction

6.13. Prove that $1 \cdot 1! + 2 \cdot 2! + \cdots + n \cdot n! = (n + 1)! - 1$ for every positive integer $n$.

6.14. Prove that $2! \cdot 4! \cdot 6! \cdots (2n)! \geq [(n + 1)!]^n$ for every positive integer $n$.

6.15. Prove that $\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{n}} \leq 2\sqrt{n} - 1$ for every positive integer $n$.

6.16. Prove that $7 \mid [3^{4n+1} - 5^{2n-1}]$ for every positive integer $n$.

6.2 A MORE GENERAL PRINCIPLE OF MATHEMATICAL INDUCTION

The Principle of Mathematical Induction, described in the preceding section, gives us a technique for proving that a statement of the type

For every positive integer $n$, $P(n)$.

is true. There are situations, however, when the domain of $P(n)$ consists of those integers greater than or equal to some fixed integer $m$ different from 1. We now describe an analogous technique to verify the truth of a statement of the following type where $m$ denotes some fixed integer:

For every integer $n \geq m$, $P(n)$.

According to the Well-Ordering Principle, the set $\mathbb{N}$ of natural numbers is well-ordered, that is, every nonempty subset of $\mathbb{N}$ has a least element. As a consequence of the Well-Ordering Principle, other sets are also well-ordered.

**Theorem 6.7** For each integer $m$, the set

$$S = \{i \in \mathbb{Z} : i \geq m\}$$

is well-ordered.

The proof of Theorem 6.7 is left as an exercise (see Exercise 6.17). The following is a consequence of Theorem 6.7. This is a slightly more general form of the Principle of Mathematical Induction. Consequently, it is commonly referred to by the same name.

**Theorem 6.8** (The Principle of Mathematical Induction) For a fixed integer $m$, let $S = \{i \in \mathbb{Z} : i \geq m\}$. For each integer $n \in S$, let $P(n)$ be a statement. If

1. $P(m)$ is true and
2. the implication
   
   If $P(k)$, then $P(k + 1)$.

is true for every integer $k \in S$,

then $P(n)$ is true for every integer $n \in S$.

The proof of Theorem 6.8 is similar to the proof of Theorem 6.2. We also state Theorem 6.8 symbolically.
6.2 A More General Principle of Mathematical Induction

For a fixed integer \( m \), let \( S = \{ i \in \mathbb{Z} : i \geq m \} \). For each \( n \in S \), let \( P(n) \) be a statement. If

1. \( P(m) \) is true and
2. \( \forall k \in S, \ P(k) \Rightarrow P(k + 1) \) is true,

then \( \forall n \in S, \ P(n) \) is true.

This (more general) Principle of Mathematical Induction can be used to prove that certain quantified statements of the type \( \forall n \in S, \ P(n) \) are true when \( S = \{ i \in \mathbb{Z} : i \geq m \} \) for a prescribed integer \( m \). Of course, if \( m = 1 \), then \( S = \mathbb{N} \). We now consider several examples.

**Result 6.9** For every nonnegative integer \( n \),

\[ 2^n > n. \]

**Proof** We proceed by induction. The inequality holds for \( n = 0 \) since \( 2^0 > 0 \). Assume that \( 2^k > k \), where \( k \) is a nonnegative integer. We show that \( 2^{k+1} > k + 1 \). When \( k = 0 \), we have \( 2^{k+1} = 2 > 1 = k + 1 \). We therefore assume that \( k \geq 1 \). Then

\[ 2^{k+1} = 2 \cdot 2^k > 2k = k + k \geq k + 1. \]

By the Principle of Mathematical Induction, \( 2^n > n \) for every nonnegative integer \( n \). ■

**PROOF ANALYSIS** Let’s review the proof of Result 6.9. First, since Result 6.9 concerns nonnegative integers, we are applying Theorem 6.8 when \( m = 0 \). We began by observing that \( 2^n > n \) when \( n = 0 \). Next we assumed that \( 2^k > k \), where \( k \) is a nonnegative integer. Our goal was to show that \( 2^{k+1} > k + 1 \). It seems logical to observe that \( 2^{k+1} = 2 \cdot 2^k \). Since we knew that \( 2^k > k \), we have \( 2^{k+1} = 2 \cdot 2^k > 2k \). If we could show that \( 2k \geq k + 1 \), then we have a proof. However, when \( k = 0 \), the inequality \( 2k \geq k + 1 \) doesn’t hold. That’s why we handled \( k = 0 \) separately in the proof. This allowed us to assume that \( k \geq 1 \) and then conclude that \( 2k \geq k + 1 \).

We could have proved Result 6.9 a bit differently. We could have observed first that \( 2^n > n \) when \( n = 0 \) and then proved that \( 2^n > n \) for \( n \geq 1 \) by induction. ☐

Our next example is to show that \( 2^n > n^2 \) if \( n \) is a sufficiently large integer. We begin by trying a few values of \( n \), as shown below. It appears that \( 2^n > n^2 \) whenever \( n \geq 5 \).

Comparing \( 2^n \) and \( n^2 \)
Chapter 6  Mathematical Induction

Result to Prove  For every integer \( n \geq 5 \),

\[ 2^n > n^2. \]

Proof Strategy  Let’s see what an induction proof of this result might look like. Of course, \( 2^n > n^2 \) when \( n = 5 \). We assume that \( 2^k > k^2 \) where \( k \geq 5 \) (and \( k \) is an integer) and we want to prove that \( 2^{k+1} > (k+1)^2 \). We start with

\[ 2^{k+1} = 2 \cdot 2^k > 2k^2. \]

We would have a proof if we could show that \( 2k^2 \geq (k+1)^2 \) or that \( 2k^2 \geq k^2 + 2k + 1 \). There are several convincing ways to show that \( 2k^2 \geq k^2 + 2k + 1 \) for integers \( k \geq 5 \). Here’s one way:

Observe that \( 2k^2 = k^2 + k \cdot k \geq k^2 + 5k \) since \( k \geq 5 \). Also \( k^2 + 5k = k^2 + 2k + 3k \geq k^2 + 2k + 3 \cdot 5 = k^2 + 2k + 15 \), again since \( k \geq 5 \). Finally, \( k^2 + 2k + 15 > k^2 + 2k + 1 \). We now present a formal proof. (Here we are using the Principle of Mathematical Induction with \( m = 5 \).)

Result 6.10  For every integer \( n \geq 5 \),

\[ 2^n > n^2. \]

Proof  We proceed by induction. Since \( 2^5 > 5^2 \), the inequality holds for \( n = 5 \). Assume that \( 2^k > k^2 \) where \( k \geq 5 \). We show that \( 2^{k+1} > (k+1)^2 \). Observe that

\[
\begin{align*}
2^{k+1} &= 2 \cdot 2^k > 2k^2 = k^2 + k \cdot k \geq k^2 + 5k \\
&= k^2 + 2k + 3k \geq k^2 + 2k + 15 \\
&> k^2 + 2k + 1 = (k+1)^2.
\end{align*}
\]

Therefore, \( 2^{k+1} > (k+1)^2 \). By the Principle of Mathematical Induction, \( 2^n > n^2 \) for every integer \( n \geq 5 \).

Result 6.11  For every nonnegative integer \( n \),

\[ 3 \mid (2^{2n} - 1). \]

Proof  We proceed by induction. The result is true when \( n = 0 \) since in this case \( 2^{2n} - 1 = 0 \) and \( 3 \mid 0 \). Assume that \( 3 \mid (2^{2k} - 1) \), where \( k \) is a nonnegative integer. We show that \( 3 \mid (2^{2k+2} - 1) \). Since \( 3 \mid (2^{2k} - 1) \), there exists an integer \( x \) such that \( 2^{2k} - 1 = 3x \) and so \( 2^{2k} = 3x + 1 \). Now,

\[
2^{2k+2} - 1 = 4 \cdot 2^{2k} - 1 = 4(3x + 1) - 1 = 12x + 3 = 3(4x + 1).
\]

Since \( 4x + 1 \) is an integer, \( 3 \mid (2^{2k+2} - 1) \).

By the Principle of Mathematical Induction, \( 3 \mid (2^{2n} - 1) \) for every nonnegative integer \( n \).

Proof Analysis  Let’s review the preceding proof. As expected, to establish the inductive step, we assumed that \( 3 \mid (2^{2k} - 1) \) for an arbitrary nonnegative integer \( k \) and attempted to show that \( 3 \mid (2^{2k+2} - 1) \). To verify that \( 3 \mid (2^{2k+2} - 1) \), it was necessary to show that \( 2^{2k+2} - 1 \)
is a multiple of 3, that is, we needed to show that $2^{2k+2} - 1$ can be expressed as $3z$ for some integer $z$. Since our goal was to show that $2^{2k+2} - 1$ can be expressed in a certain form, it is natural to consider $2^{2k+2} - 1$ and see how we might write it. Since we knew that $2^{2k} - 1 = 3x$, where $x \in \mathbb{Z}$, it was logical to rewrite $2^{2k+2} - 1$ so that $2^{2k}$ appears. Actually, this is quite easy since

$$2^{2k} + 2^{2k} - 1 = 4 \cdot 2^{2k} - 1.$$ 

At this point, we need to be a bit careful because the expression we are currently considering is $4 \cdot 2^{2k} - 1$, not $4(2^{2k} - 1)$. That is, it would be incorrect to say that $4 \cdot 2^{2k} - 1 = 4(3x)$. Hence, we need to substitute for $2^{2k}$ in this case, not for $2^{2k} - 1$. This is the reason that in the proof we rewrote $2^{2k} - 1 = 3x$ as $2^{2k} = 3x + 1$.

\[\Box\]

While the proof of Result 6.11 used the Principle of Mathematical Induction, which we are illustrating in this chapter, an even simpler proof exists. In Result 4.6(a), we saw for an integer $x$ that if $3 \mid x$, then $3 \mid x^2$; while if $3 \nmid x$, then $3 \mid (x^2 - 1)$. For every nonnegative integer $n$, the integer $2^n$ is not a multiple of 3, that is, $3 \nmid 2^n$. Hence, by Result 4.6(a), $3 \mid (2^n)^2 - 1$ or, equivalently, $3 \mid (2^{2n} - 1)$.

We reinforce proof by mathematical induction with another example.

**Result 6.12**

For every nonnegative integer $n$,

$$9 \mid (4^{3n} - 1).$$

**Proof**

We proceed by induction. When $n = 0$, $4^{3n} - 1 = 0$. Since $9 \mid 0$, the statement is true when $n = 0$. Assume that $9 \mid (4^{3k} - 1)$, where $k$ is a nonnegative integer. We now show that $9 \mid (4^{3k+3} - 1)$. Since $9 \mid (4^{3k} - 1)$, it follows that $4^{3k} - 1 = 9x$ for some integer $x$. Hence, $4^{3k} = 9x + 1$. Now, observe that

$$4^{3k+3} - 1 = 4^3 \cdot 4^{3k} - 1 = 64(9x + 1) - 1$$

$$= 64 \cdot 9x + 64 - 1 = 64 \cdot 9x + 63$$

$$= 9(64x + 7).$$

Since $64x + 7$ is an integer, $9 \mid (4^{3k+3} - 1)$.

By the Principle of Mathematical Induction, $9 \mid (4^{3n} - 1)$ for every nonnegative integer $n$.

\[\Box\]

As a final comment regarding the preceding proof, notice that we did not multiply 64 and 9 since we were about to factor 9 from the expression in the next step in any case. For a positive integer $n$, the integer $n$ factorial, denoted by $n!$, is defined as

$$n! = n(n - 1) \cdots 3 \cdot 2 \cdot 1.$$ 

In particular, $1! = 1$, $2! = 2 \cdot 1 = 2$ and $3! = 3 \cdot 2 \cdot 1 = 6$. Also, $0!$ is defined as $0! = 1$. Among the many equalities and inequalities involving $n!$ is the following.
Chapter 6  Mathematical Induction

Result to Prove  For every positive integer \( n \),
\[
1 \cdot 3 \cdot 5 \cdots (2n - 1) = \frac{(2n)!}{2^n \cdot n!}.
\]

Proof Strategy  First, observe that
\[
(2n)! = 2n \cdot (2n - 1) \cdot (2n - 2) \cdots 3 \cdot 2 \cdot 1. \tag{6.7}
\]
Of the \( 2n \) terms in the right side of expression (6.7), \( n \) of them are even, namely 2, 4, 6, \ldots, 2n. If we were to factor 2 from each of these numbers, we obtain
\[
2^n \cdot 1 \cdot 2 \cdot 3 \cdots n = 2^n \cdot n!,
\]
while the remaining \( n \) integers, namely 1, 3, 5, \ldots, \( 2n - 1 \), are all odd. Thus
\[
(2n)! = 2^n \cdot n! \cdot 1 \cdot 3 \cdot 5 \cdots (2n - 1).
\]
Therefore,
\[
1 \cdot 3 \cdot 5 \cdots (2n - 1) = \frac{(2n)!}{2^n \cdot n!}.
\]
This equality can also be established by induction. ♦

Result 6.13  For every positive integer \( n \),
\[
1 \cdot 3 \cdot 5 \cdots (2n - 1) = \frac{(2n)!}{2^n \cdot n!}.
\]

Proof  We proceed by induction. Since
\[
1 = \frac{(2 \cdot 1)!}{2! \cdot 1!} = \frac{2}{2} = 1,
\]
the statement is true for \( n = 1 \). Assume, for a positive integer \( k \), that
\[
1 \cdot 3 \cdot 5 \cdots (2k - 1) = \frac{(2k)!}{2^k \cdot k!}.
\]
We show that
\[
1 \cdot 3 \cdot 5 \cdots (2k + 1) = \frac{(2k + 2)!}{2^{k+1} \cdot (k + 1)!}.
\]
Observe that
\[
\frac{(2k + 2)!}{2^{k+1} \cdot (k + 1)!} = \frac{(2k + 2)(2k + 1)}{2 \cdot (k + 1)} \cdot \frac{(2k)!}{2^k \cdot (k)!} = \frac{(2k + 1)[1 \cdot 3 \cdot 5 \cdots (2k - 1)]}{2 \cdot (k + 1)} = 1 \cdot 3 \cdot 5 \cdots (2k + 1).
\]
By the Principle of Mathematical Induction,
\[
1 \cdot 3 \cdot 5 \cdots (2n - 1) = \frac{(2n)!}{2^n \cdot n!}
\]
for every positive integer \( n \). ■

We saw in Theorem 3.12 that for an integer \( x \), its square \( x^2 \) is even if and only if \( x \) is even. This is actually a consequence of Theorem 3.17, which states that for integers \( a \) and
6.2 A More General Principle of Mathematical Induction

Let \( x \in \mathbb{Z} \). For every integer \( n \geq 2 \), \( x^n \) is even if and only if \( x \) is even.

**Proof**

Assume, first, that \( x \) is even. Then \( x = 2y \) for some integer \( y \). Hence,

\[
x^n = x \cdot x^{n-1} = (2y)x^{n-1} = 2\left(yx^{n-1}\right).
\]

Since \( yx^{n-1} \) is an integer, \( x^n \) is even.

We now verify the converse, namely if \( x^n \) is even, where \( n \geq 2 \), then \( x \) is even. We proceed by induction. If \( x^2 \) is even, then we have already seen that \( x \) is even. Hence, the statement is true for \( n = 2 \). Assume that if \( x^k \) is even for some integer \( k \geq 2 \), then \( x \) is even. We show that if \( x^{k+1} \) is even, then \( x \) is even. Let \( x^{k+1} \) be an even integer. Then \( x \cdot x^k \) is even. By Theorem 3.17, \( x \) is even or \( x^k \) is even. If \( x \) is even, then the result is proved. On the other hand, if \( x^k \) is even, then, by the induction hypothesis, \( x \) is even as well. By the Principle of Mathematical Induction, it follows, for every integer \( n \geq 2 \), that if \( x^n \) is even, then \( x \) is even.

Although it is impossible to illustrate every type of result where induction can be used, we give two examples that are considerably different than those we have seen.

One of De Morgan’s laws (see Theorem 4.22) states that

\[
\overline{A \cup B} = \overline{A} \cap \overline{B}
\]

for every two sets \( A \) and \( B \). It is possible to use this law to show that

\[
\overline{A \cup B \cup C} = \overline{A} \cap \overline{B} \cap \overline{C}
\]

for every three sets \( A, B \) and \( C \). We show how induction can be used to prove De Morgan’s law for any finite number of sets.

**Theorem 6.15**

If \( A_1, A_2, \ldots, A_n \) are \( n \geq 2 \) sets, then

\[
\overline{A_1 \cup A_2 \cup \cdots \cup A_n} = \overline{A_1} \cap \overline{A_2} \cap \cdots \cap \overline{A_n}.
\]

**Proof**

We proceed by induction. For \( n = 2 \), the result is De Morgan’s Law and is therefore true. Assume that the result is true for any \( k \) sets, where \( k \geq 2 \); that is, assume that if \( B_1, B_2, \ldots, B_k \) are any \( k \) sets, then

\[
\overline{B_1 \cup B_2 \cup \cdots \cup B_k} = \overline{B_1} \cap \overline{B_2} \cap \cdots \cap \overline{B_k}.
\]

We prove that the result is true for any \( k + 1 \) sets. Let \( S_1, S_2, \ldots, S_{k+1} \) be \( k + 1 \) sets. We show that

\[
\overline{S_1 \cup S_2 \cup \cdots \cup S_{k+1}} = \overline{S_1} \cap \overline{S_2} \cap \cdots \cap \overline{S_{k+1}}.
\]

Let \( T = S_1 \cup S_2 \cup \cdots \cup S_k \). Then

\[
\overline{S_1 \cup S_2 \cup \cdots \cup S_{k+1}} = (\overline{S_1 \cup S_2 \cup \cdots \cup S_k}) \cup S_{k+1} = T \cup S_{k+1}.
\]

Now, by De Morgan’s Law,

\[
\overline{T \cup S_{k+1}} = T \cap \overline{S_{k+1}}.
\]
Mathematical Induction

By the definition of $T$ and by the inductive hypothesis, we have

$$T = S_1 \cup S_2 \cup \cdots \cup S_k = S_1 \cap S_2 \cap \cdots \cap S_k.$$  

Therefore,

$$\overline{S_1 \cup S_2 \cup \cdots \cup S_{k+1}} = \overline{T} = \overline{S_{k+1}}$$

$$= \overline{S_1} \cap \overline{S_2} \cap \cdots \cap \overline{S_k} \cap \overline{S_{k+1}}.$$  

By the Principle of Mathematical Induction, for every $n \geq 2$, sets $A_1, A_2, \ldots, A_n$,

$$A_1 \cup A_2 \cup \cdots \cup A_n = \overline{A_1} \cap \overline{A_2} \cap \cdots \cap \overline{A_n},$$

as desired. \[\square\]

**Proof Analysis**

A few comments may be useful concerning the notation used in the statement and the proof of Theorem 6.15. First, the sets $A_1, A_2, \ldots, A_n$ were used in the statement of Theorem 6.15 only as an aid to describe the result. Theorem 6.15 could have also been stated as:

For every integer $n \geq 2$, the complement of the union of any $n$ sets equals the intersection of the complements of these sets.

To verify the inductive step in the proof of Theorem 6.15, we assumed that the statement is true for any $k \geq 2$ sets, which we denoted by $B_1, B_2, \ldots, B_k$. The fact that we used $A_1, A_2, \ldots, A_n$ to describe the statement of Theorem 6.15 did not mean that we should use $A_1, A_2, \ldots, A_n$ for the $k$ sets in the inductive hypothesis. In fact, it is probably better that we do not use this notation. In the inductive step, we now need to show that the result is true for any $k + 1$ sets. We used $S_1, S_2, \ldots, S_{k+1}$ for these sets. It would have been a bad idea to denote the $k + 1$ sets by $B_1, B_2, \ldots, B_{k+1}$ because that would have (improperly) suggested that $k$ of the $k + 1$ sets must specifically be the sets mentioned in the inductive hypothesis. ♦

We are now able to prove another well-known theorem concerning sets, to which we earlier referred.

**Theorem 6.16**

If $A$ is a finite set of cardinality $n \geq 0$, then the cardinality of its power set $\mathcal{P}(A)$ is $2^n$.

**Proof**

We proceed by induction. If $A$ is a set with $|A| = 0$, then $A = \emptyset$. Thus, $\mathcal{P}(A) = \{\emptyset\}$ and so $|\mathcal{P}(A)| = 1 = 2^0$. Therefore, the theorem is true for $n = 0$. Assume that if $B$ is any set with $|B| = k$ for some nonnegative integer $k$, then $|\mathcal{P}(B)| = 2^k$. We show that if $C$ is a set with $|C| = k + 1$, then $|\mathcal{P}(C)| = 2^{k+1}$. Let

$$C = \{c_1, c_2, \ldots, c_{k+1}\}.$$  

By the inductive hypothesis, there are $2^k$ subsets of the set $\{c_1, c_2, \ldots, c_k\}$, that is, there are $2^k$ subsets of $C$ not containing $c_{k+1}$. Any subset of $C$ containing $c_{k+1}$ can be expressed as $D \cup \{c_{k+1}\}$, where $D \subseteq \{c_1, c_2, \ldots, c_k\}$. Again, by the inductive hypothesis, there are $2^k$ such subsets $D$. Therefore, there are $2^k + 2^k = 2 \cdot 2^k = 2^{k+1}$ subsets of $C$. 
By the Principle of Mathematical Induction, it follows for every nonnegative integer \( n \) that if \(|A| = n\), then \(|P(A)| = 2^n\).

Of course, Theorem 6.16 could also be stated as:

*The number of subsets of a finite set with \( n \) elements is \( 2^n \).*

### Section 6.2 Exercises

6.17. Prove Theorem 6.7: For each integer \( m \), the set \( S = \{ i \in \mathbb{Z} : i \geq m \} \) is well-ordered. [Hint: For every subset \( T \) of \( S \), either \( T \subseteq \mathbb{N} \) or \( T - \mathbb{N} \) is a finite nonempty set.]

6.18. Prove that \( 2^n > n^3 \) for every integer \( n \geq 10 \).

6.19. Prove the following implication for every integer \( n \geq 2 \): If \( x_1, x_2, \ldots, x_n \) are any \( n \) real numbers such that \( x_1 \cdot x_2 \cdot \cdots \cdot x_n = 0 \), then at least one of the numbers \( x_1, x_2, \ldots, x_n \) is 0. (Use the fact that if the product of two real numbers is 0, then at least one of the numbers is 0.)

6.20. (a) Use mathematical induction to prove that every finite nonempty set of real numbers has a largest element.

(b) Use (a) to prove that every finite nonempty set of real numbers has a smallest element.

6.21. Prove that \( 4^n \mid (5^n - 1) \) for every nonnegative integer \( n \).

6.22. Prove that \( 3^n > n^2 \) for every positive integer \( n \).

6.23. Prove that \( 7 \mid (3^{2n} - 2^n) \) for every nonnegative integer \( n \).

6.24. Prove the following implication for every integer \( n \geq 2 \): If \( x_1, x_2, \ldots, x_n \) are any \( n \) real numbers such that \( x_1 \cdot x_2 \cdot \cdots \cdot x_n = 0 \), then at least one of the numbers \( x_1, x_2, \ldots, x_n \) is 0. (Use the fact that if the product of two real numbers is 0, then at least one of the numbers is 0.)

6.25. Prove that \( n! > 2^n \) for every integer \( n \geq 4 \).

6.26. Prove that \( 81 \mid (10^{n+1} - 9n - 10) \) for every nonnegative integer \( n \).

6.27. Prove that \( 1 + \frac{1}{4} + \frac{1}{9} + \cdots + \frac{1}{n^2} \leq 2 - \frac{1}{n} \) for every positive integer \( n \).

6.28. In Exercise 4.6 of Chapter 4, you were asked to prove that if \( 3 \mid 2a \), where \( a \in \mathbb{Z} \), then \( 3 \mid a \). Assume that this result is true. Prove the following generalization: Let \( a \in \mathbb{Z} \). For every positive integer \( n \), if \( 3 \mid 2^n a \), then \( 3 \mid a \).

6.29. Prove that if \( A_1, A_2, \ldots, A_n \) are any \( n \geq 2 \) sets, then

\[
A_1 \cap A_2 \cap \cdots \cap A_n = \overline{A_1} \cup \overline{A_2} \cup \cdots \cup \overline{A_n}.
\]

6.30. Recall for integers \( n \geq 2, a, b, c, d \), that if \( a \equiv b \pmod{n} \) and \( c \equiv d \pmod{n} \), then both \( a + c \equiv b + d \pmod{n} \) and \( ac \equiv bd \pmod{n} \). Use these results and mathematical induction to prove the following: For any \( 2m \) integers \( a_1, a_2, \ldots, a_m \) and \( b_1, b_2, \ldots, b_m \) for which \( a_i \equiv b_i \pmod{n} \) for \( 1 \leq i \leq m \),

(a) \( a_1 + a_2 + \cdots + a_m \equiv b_1 + b_2 + \cdots + b_m \pmod{n} \)

(b) \( a_1 a_2 \cdots a_m \equiv b_1 b_2 \cdots b_m \pmod{n} \).

6.31. We saw in Exercise 5.7(a) that \( (a + b)(\frac{1}{a} + \frac{1}{b}) \geq 4 \) for every two positive real numbers \( a \) and \( b \). Prove for every \( n \geq 1 \) positive real numbers \( a_1, a_2, \ldots, a_n \) that

\[
\left( \sum_{i=1}^{n} a_i \right) \left( \sum_{i=1}^{n} \frac{1}{a_i} \right) \geq n^2.
\]
6.32. Prove for every $n \geq 2$ positive real numbers $a_1, a_2, \ldots, a_n$ that

$$\sum_{i=1}^{n} (n-1)a_i^2 \geq 2 \sum_{1 \leq i < j \leq n} a_i a_j. \quad (6.8)$$

[Note: When $n = 4$, for example, (6.8) states that

$$3(a_1^2 + a_2^2 + a_3^2 + a_4^2) \geq 2(a_1a_2 + a_1a_3 + a_1a_4 + a_2a_3 + a_2a_4 + a_3a_4).]$$

6.3 THE STRONG PRINCIPLE OF MATHEMATICAL INDUCTION

There is one last form of mathematical induction. This principle goes by many names: the Strong Principle of Mathematical Induction, the Strong Form of Induction, the Alternate Form of Mathematical Induction and the Second Principle of Mathematical Induction are common names.

**Theorem 6.17** (The Strong Principle of Mathematical Induction) For each positive integer $n$, let $P(n)$ be a statement. If

(a) $P(1)$ is true and

(b) the implication

If $P(i)$ for every integer $i$ with $1 \leq i \leq k$, then $P(k+1)$.

is true for every positive integer $k$,

then $P(n)$ is true for every positive integer $n$.

As with the Principle of Mathematical Induction (Theorem 6.2), the Strong Principle of Mathematical Induction is also a consequence of the Well-Ordering Principle. The Strong Principle of Mathematical Induction is now stated more symbolically below.

**The Strong Principle of Mathematical Induction**

For each positive integer $n$, let $P(n)$ be a statement. If

1. $P(1)$ is true and
2. $\forall k \in \mathbb{N}, P(1) \land P(2) \land \cdots \land P(k) \Rightarrow P(k+1)$ is true,

then $\forall n \in \mathbb{N}, P(n)$ is true.

The difference in the statements of the Principle of Mathematical Induction and the Strong Principle of Mathematical Induction lies in the inductive step (condition 2). To prove that $\forall n \in \mathbb{N}, P(n)$ is true by the Principle of Mathematical Induction, we are required to show that $P(1)$ is true and to verify the implication:

If $P(k)$, then $P(k+1). \quad (6.9)$

is true for every positive integer $k$. On the other hand, to prove $\forall n \in \mathbb{N}, P(n)$ is true by the Strong Principle of Mathematical Induction, we are required to show that $P(1)$ is true and to verify the implication:

If $P(i)$ for every $i$ with $1 \leq i \leq k$, then $P(k+1). \quad (6.10)$
The Strong Principle of Mathematical Induction

is true for every positive integer \( k \). If we were to give direct proofs of the implications (6.9) and (6.10), then we are permitted to assume more in the inductive step (6.10) of the Strong Principle of Mathematical Induction than in the induction step (6.9) of the Principle of Mathematical Induction and yet obtain the same conclusion. If the assumption that \( P(k) \) is true is insufficient to verify the truth of \( P(k+1) \) for an arbitrary positive integer \( k \), but the assumption that all of the statements \( P(1), P(2), \ldots, P(k) \) are true is sufficient to verify the truth of \( P(k+1) \), then this suggests that we should use the Strong Principle of Mathematical Induction. Indeed, any result that can be proved by the Principle of Mathematical Induction can also be proved by the Strong Principle of Mathematical Induction.

Just as there is a more general version of the Principle of Mathematical Induction (namely, Theorem 6.2), there is a more general version of the Strong Principle of Mathematical Induction. We shall also refer to this as the Strong Principle of Mathematical Induction.

**Theorem 6.18 (The Strong Principle of Mathematical Induction)** For a fixed integer \( m \), let \( S = \{ i \in \mathbb{Z} : i \geq m \} \). For each \( n \in S \), let \( P(n) \) be a statement. If

1. \( P(m) \) is true and
2. the implication

   If \( P(i) \) for every integer \( i \) with \( m \leq i \leq k \), then \( P(k+1) \).

then \( P(n) \) is true for every integer \( n \in S \).

We now consider a class of mathematical statements where the Strong Principle of Mathematical Induction is commonly the appropriate proof technique.

Suppose that we are considering a sequence \( a_1, a_2, a_3, \ldots \) of numbers, also expressed as \( \{a_n\} \). One way of defining a sequence \( \{a_n\} \) is to specify explicitly the \( n \)th term \( a_n \) (as a function of \( n \)). For example, we might have \( a_n = \frac{1}{n} \), \( a_n = \frac{(-1)^n}{n^2} \) or \( a_n = n^3 + n \) for each \( n \in \mathbb{N} \). A sequence can also be defined recursively. In a recursively-defined sequence \( \{a_n\} \), only the first term or perhaps the first few terms are defined specifically, say \( a_1, a_2, \ldots, a_k \) for some fixed \( k \in \mathbb{N} \). These are called the initial values. Then \( a_{k+1} \) is expressed in terms of \( a_1, a_2, \ldots, a_k \) and, more generally, for \( n > k, a_n \) is expressed in terms of \( a_1, a_2, \ldots, a_{n-1} \). This is called the recurrence relation.

A specific example of this is the sequence \( \{a_n\} \) defined by \( a_1 = 1, a_2 = 3 \) and \( a_n = 2a_{n-1} - a_{n-2} \) for \( n \geq 3 \). In this case, there are two initial values, namely \( a_1 = 1 \) and \( a_2 = 3 \). The recurrence relation here is

\[
a_n = 2a_{n-1} - a_{n-2} \text{ for } n \geq 3.
\]

Letting \( n = 3 \), we find that \( a_3 = 2a_2 - a_1 = 5 \); while letting \( n = 4 \), we have \( a_4 = 2a_3 - a_2 = 7 \). Similarly, \( a_5 = 9 \) and \( a_6 = 11 \). From this information, one might well conjecture (guess) that \( a_n = 2n - 1 \) for every \( n \in \mathbb{N} \). (Conjectures will be discussed in more detail in Section 8.1.) Using the Strong Principle of Mathematical Induction, we can, in fact, prove that this conjecture is true.
A sequence \( \{a_n\} \) is defined recursively by
\[
a_1 = 1, \quad a_2 = 3 \quad \text{and} \quad a_n = 2a_{n-1} - a_{n-2} \quad \text{for} \quad n \geq 3.
\]
Then \( a_n = 2n - 1 \) for all \( n \in \mathbb{N} \).

**Proof**
We proceed by induction. Since \( a_1 = 2 \cdot 1 - 1 = 1 \), the formula holds for \( n = 1 \). Assume for an arbitrary positive integer \( k \) that \( a_i = 2i - 1 \) for all integers \( i \) with \( 1 \leq i \leq k \). We show that \( a_{k+1} = 2(k + 1) - 1 = 2k + 1 \). If \( k = 1 \), then \( a_{k+1} = a_2 = 2 \cdot 1 + 1 = 3 \). Since \( a_2 = 3 \), it follows that \( a_{k+1} = 2k + 1 \) when \( k = 1 \). Hence, we may assume that \( k \geq 2 \). Since \( k + 1 \geq 3 \), it follows that
\[
a_{k+1} = 2a_k - a_{k-1} = 2(2k - 1) - (2k - 3) = 2k + 1,
\]
which is the desired result. By the Strong Principle of Mathematical Induction, \( a_n = 2n - 1 \) for all \( n \in \mathbb{N} \).

**Proof Analysis**
A few comments about the proof of Result 6.19 are in order. At one point, we assumed for an arbitrary positive integer \( k \) that \( a_i = 2i - 1 \) for all integers \( i \) with \( 1 \leq i \leq k \). Our goal was to show that \( a_{k+1} = 2k + 1 \). Since \( k \) is a positive integer, it may occur that \( k = 1 \) or \( k \geq 2 \). If \( k = 1 \), then we need to show that \( a_{k+1} = a_2 = 2 \cdot 1 + 1 = 3 \). That \( a_2 = 3 \) is known because this is one of the initial values. If \( k \geq 2 \), then \( k + 1 \geq 3 \) and \( a_{k+1} \) can be expressed as \( 2a_k - a_{k-1} \) by the recurrence relation. In order to show that \( a_{k+1} = 2k + 1 \) when \( k \geq 2 \), it was necessary to know that \( a_k = 2k - 1 \) and that \( a_{k-1} = 2(k - 1) - 1 = 2k - 3 \). Because we were using the Strong Principle of Mathematical Induction, we knew both pieces of information. If we had used the Principle of Mathematical Induction, then we would have assumed (and therefore knew) that \( a_k = 2k - 1 \) but we would not have known that \( a_{k-1} = 2k - 3 \), and so we would have been unable to establish the desired expression for \( a_{k+1} \).

**Example 6.20**
A sequence \( \{a_n\} \) is defined recursively by
\[
a_1 = 1, \quad a_2 = 4 \quad \text{and} \quad a_n = 2a_{n-1} - a_{n-2} + 2 \quad \text{for} \quad n \geq 3.
\]
Conjecture a formula for \( a_n \) and verify that your conjecture is correct.

**Solution**
We begin by finding a few more terms of the sequence. Observe that \( a_3 = 2a_2 - a_1 + 2 = 9 \), while \( a_4 = 2a_3 - a_2 + 2 = 16 \) and \( a_5 = 2a_4 - a_3 + 2 = 25 \). The obvious conjecture here is that \( a_n = n^2 \) for every positive integer \( n \). We verify that this conjecture is correct in the next result.

**Result 6.21**
A sequence \( \{a_n\} \) is defined recursively by
\[
a_1 = 1, \quad a_2 = 4 \quad \text{and} \quad a_n = 2a_{n-1} - a_{n-2} + 2 \quad \text{for} \quad n \geq 3.
\]
Then \( a_n = n^2 \) for all \( n \in \mathbb{N} \).

**Proof**
We proceed by induction. Since \( a_1 = 1 = 1^2 \), the formula holds for \( n = 1 \). Assume for an arbitrary positive integer \( k \) that \( a_i = i^2 \) for every integer \( i \) with \( 1 \leq i \leq k \). We show
that \( a_{k+1} = (k+1)^2 \). Since \( a_2 = 4 \), it follows that \( a_{k+1} = (k+1)^2 \) when \( k = 1 \). Thus, we may assume that \( k \geq 2 \). Hence, \( k + 1 \geq 3 \) and so

\[
\begin{align*}
a_{k+1} &= 2a_k - a_{k-1} + 2 = 2k^2 - (k-1)^2 + 2 \\ &= 2k^2 - (k^2 - 2k + 1) + 2 = k^2 + 2k + 1 = (k+1)^2.
\end{align*}
\]

By the Strong Principle of Mathematical Induction, \( a_n = n^2 \) for all \( n \in \mathbb{N} \).

Although we mentioned that problems involving recurrence relations are commonly solved with the aid of the Strong Principle of Mathematical Induction, it is by no means the only kind of problem where the Strong Principle of Mathematical Induction can be applied. Although the best examples of this require a knowledge of mathematics beyond what we have covered thus far, we do present another type of example, namely an example of the type given in Result 5.26. Indeed, the following result appears as Exercise 5.51 but here we give a proof using the Strong Principle of Mathematical Induction.

**Result 6.22** For each integer \( n \geq 8 \), there are nonnegative integers \( a \) and \( b \) such that \( n = 3a + 5b \).

**Proof** We proceed by induction. Since \( 8 = 3 \cdot 1 + 5 \cdot 1 \), the statement is true for \( n = 8 \). Assume for each integer \( i \) with \( 8 \leq i \leq k \), where \( k \geq 8 \) is an arbitrary integer, that there are nonnegative integers \( s \) and \( t \) such that \( i = 3s + 5t \). Consider the integer \( k + 1 \). We show that there are nonnegative integers \( x \) and \( y \) such that \( k + 1 = 3x + 5y \). Since \( 9 = 3 \cdot 3 + 5 \cdot 0 \) and \( 10 = 3 \cdot 0 + 5 \cdot 2 \), this is true if \( k + 1 = 9 \) and \( k + 1 = 10 \). Hence, we may assume that \( k + 1 \geq 11 \). Thus, \( 8 \leq (k+1) - 3 < k \). By the induction hypothesis, there are nonnegative integers \( a \) and \( b \) such that

\[
(k + 1) - 3 = 3a + 5b \quad \text{and so} \quad k + 1 = 3(a + 1) + 5b.
\]

Letting \( x = a + 1 \) and \( y = b \), we have the desired conclusion.

By the Strong Principle of Mathematical Induction, for every integer \( n \geq 8 \), there are nonnegative integers \( a \) and \( b \) such that \( n = 3a + 5b \).

We close this section with a result of a different type whose proof uses the Strong Principle of Mathematical Induction. First, we observe that for the irrational number \( r = \frac{3+\sqrt{5}}{2} \), it follows that \( r + \frac{1}{r} = 3 \).

**Result 6.23** If \( r \) is a nonzero real number such that \( r + \frac{1}{r} \) is an integer, then \( r^n + \frac{1}{r^n} \) is an integer for every positive integer \( n \).

**Proof** We use the Strong Principle of Mathematical Induction. Let \( r \) be a nonzero real number such that \( r + \frac{1}{r} = \) is an integer. Since \( r + \frac{1}{r} = r^1 + \frac{1}{r^1} \) is an integer, the statement is true for \( n = 1 \). Assume for an arbitrary integer \( k \geq 1 \) that \( m_k = r^i + \frac{1}{r^i} \) is an integer for every integer \( i \) with \( 1 \leq i \leq k \). We show that \( r^{k+1} + \frac{1}{r^{k+1}} \) is an integer. Observe that

\[
r^{k+1} + \frac{1}{r^{k+1}} = \left( r^k + \frac{1}{r^k} \right) \left( r + \frac{1}{r} \right) - \left( r^{k-1} + \frac{1}{r^{k-1}} \right) = m_k m_1 - m_{k-1} \in \mathbb{Z}.
\]
174 Chapter 6 Mathematical Induction

By the Strong Principle of Mathematical Induction, if \( r \) is a nonzero real number such that \( r + \frac{1}{r} \in \mathbb{Z} \), then \( r^n + \frac{1}{r^n} \in \mathbb{Z} \) for every positive integer \( n \).  

SECTION 6.3 EXERCISES

6.33. A sequence \( \{a_n\} \) is defined recursively by \( a_1 = 1 \) and \( a_n = 2a_{n-1} \) for \( n \geq 2 \). Conjecture a formula for \( a_n \) and verify that your conjecture is correct.

6.34. A sequence \( \{a_n\} \) is defined recursively by \( a_1 = 1 \), \( a_2 = 2 \) and \( a_n = a_{n-1} + 2a_{n-2} \) for \( n \geq 3 \). Conjecture a formula for \( a_n \) and verify that your conjecture is correct.

6.35. A sequence \( \{a_n\} \) is defined recursively by \( a_1 = 1 \), \( a_2 = 4 \), \( a_3 = 9 \) and

\[
a_n = a_{n-1} - a_{n-2} + a_{n-3} + 2(2n - 3)
\]

for \( n \geq 4 \). Conjecture a formula for \( a_n \) and prove that your conjecture is correct.

6.36. Consider the sequence \( F_1, F_2, F_3, \ldots \), where

\[
F_1 = 1, \quad F_2 = 1, \quad F_3 = 2, \quad F_4 = 3, \quad F_5 = 5 \quad \text{and} \quad F_6 = 8.
\]

The terms of this sequence are called Fibonacci numbers.

(a) Define the sequence of Fibonacci numbers by means of a recurrence relation.

(b) Prove that \( 2 \mid F_n \) if and only if \( 3 \mid n \).

6.37. Exercise 5.52 asked for a proof of the following statement: For each integer \( n \geq 12 \), there exist nonnegative integers \( a \) and \( b \) such that \( n = 3a + 7b \). Use the Strong Principle of Mathematical Induction to give an alternative proof of this statement.

6.38. Use the Strong Principle of Mathematical Induction to prove the following. Let \( S = \{ i \in \mathbb{Z} : i \geq 2 \} \) and let \( P \) be a subset of \( S \) with the properties that \( 2, 3 \in P \) and if \( n \in S \), then either \( n \in P \) or \( n = ab \), where \( a, b \in S \). Then every element of \( S \) either belongs to \( P \) or can be expressed as a product of elements of \( P \). [Note: You might recognize the set \( P \) of primes. This is an important theorem in mathematics which appears as Theorem 12.17 in Chapter 12.]

6.39. Prove that there exists an odd integer \( m \) such that every odd integer \( n \) with \( n \geq m \) can be expressed either as \( 3a + 11b \) or as \( 5c + 7d \) for nonnegative integers \( a, b, c \) and \( d \).

6.4 PROOF BY MINIMUM COUNTEREXAMPLE

Suppose that \( P(n) \) is a statement for each positive integer \( n \). We have seen that induction is a natural proof technique that can be used to verify the truth of the quantified statement

\[
\forall n \in \mathbb{N}, \ P(n).
\] (6.11)

There are certainly such quantified statements where induction does not work or does not work well. If we would attempt to prove (6.11) using a proof by contradiction, then we would begin such a proof by assuming that the statement \( \forall n \in \mathbb{N}, \ P(n) \) is false. Consequently, there are positive integers \( n \) such that \( P(n) \) is a false statement. By the Well-Ordering Principle, there exists a smallest positive integer \( n \) such that \( P(n) \) is a false statement. Denote this integer by \( m \). Therefore, \( P(m) \) is a false statement and for any integer \( k \) with \( 1 \leq k < m \), the statement \( P(k) \) is true. The integer \( m \) is referred to as
a minimum counterexample of the statement (6.11). If a proof (by contradiction) of \( \forall n \in \mathbb{N}, P(n) \) can be given using the fact that \( m \) is a minimum counterexample, then such a proof is called a proof by minimum counterexample.

We now illustrate this proof technique. For the example we are about to describe, it is useful to recall from algebra that

\[(a + b)^3 = a^3 + 3a^2b + 3ab^2 + b^3.\]

Suppose that we wish to prove that 6 \( \mid (n^3 - n) \) for every positive integer \( n \). An induction proof would probably start like this:

If \( n = 1 \), then \( n^3 - n = 0 \). Since 6 \( \mid 0 \), the result is true for \( n = 1 \). Assume that 6 \( \mid (k^3 - k) \), where \( k \) is a positive integer. We wish to prove that 6 \( \mid [(k + 1)^3 - (k + 1)] \). Since 6 \( \mid (k^3 - k) \), it follows that \( k^3 - k = 6x \) for some integer \( x \). Then

\[
(k + 1)^3 - (k + 1) = k^3 + 3k^2 + 3k + 1 - k - 1 = (k^3 - k) + 3k^2 + 3k = 6x + 3k(k + 1).
\]

If we can show that 6 \( \mid 3k(k + 1) \), we have a proof. To show this, we need only verify that \( k(k + 1) \) is an even integer for every positive integer \( k \). A lemma could be introduced to verify this. This lemma could be proved in two cases (\( k \) is even and \( k \) is odd) or even induction could be used. Although such a lemma would not be difficult to prove, we give an alternative proof that avoids the need for a lemma.

**Result 6.24** For every positive integer \( n \),

\[ 6 \mid (n^3 - n). \]

**Proof** Assume, to the contrary, that there are positive integers \( n \) such that 6 \( \nmid (n^3 - n) \). Then there is a smallest positive integer \( n \) such that 6 \( \nmid (n^3 - n) \). Let \( m \) be this integer. If \( n = 1 \), then \( n^3 - n = 0 \); while if \( n = 2 \), then \( n^3 - n = 6 \). Since 6 \( \mid 0 \) and 6 \( \nmid 6 \), it follows that 6 \( \nmid (n^3 - n) \) for \( n = 1 \) and \( n = 2 \). Therefore \( m \geq 3 \). So, we can write \( m = k + 2 \), where \( 1 \leq k \leq m \). Observe that

\[
m^3 - m = (k + 2)^3 - (k + 2) = (k^3 + 6k^2 + 12k + 8) - (k + 2) = (k^3 - k) + 6k^2 + 12k + 6.
\]

Since \( k < m \), it follows that 6 \( \mid (k^3 - k) \). Hence, \( k^3 - k = 6x \) for some integer \( x \). So, we have

\[
m^3 - m = 6x + 6(k^2 + 2k + 1) = 6(x + k^2 + 2k + 1).
\]

Since \( x + k^2 + 2k + 1 \) is an integer, 6 \( \mid (m^3 - m) \), which produces a contradiction. ■

**PROOF ANALYSIS** Let’s see how this proof was constructed. In this proof, \( m \) is a positive integer such that 6 \( \nmid (m^3 - m) \); while for every positive integer \( n \) with \( n < m \), we have 6 \( \mid (n^3 - n) \). We are trying to determine just how large \( m \) needs to be to obtain a contradiction. We saw that 6 \( \mid (1^3 - 1) \) and 6 \( \mid (2^3 - 2) \); so \( m \geq 3 \). Knowing that \( m \geq 3 \) allowed us to write \( m \) as \( k + 2 \), where \( 1 \leq k \leq m \). Because \( 1 \leq k \leq m \), we know that 6 \( \mid (k^3 - k) \) and so
Mathematical Induction

For every nonnegative integer \( n \),

\[
k^3 - k = 6x, \text{ where } x \in \mathbb{Z}. \text{ So, in the proof, we wrote}
\]

\[
m^3 - m = (k + 1)^3 - (k + 1) = (k^3 + 3k^2 + 3k + 1) - (k + 1)
\]

\[
= (k^3 - k) + 3k^2 + 3k = (k^3 - k) + 3k(k + 1)
\]

\[
= 6x + 3k(k + 1).
\]

As it stands, we can factor 3 from 6x + 3k(k + 1) but cannot factor 6 unless we can prove that \( k(k + 1) \) is even. This is the same difficulty we encountered when we were considering an induction proof. In any case, no contradiction is obtained.

If a result can be proved by induction, then it can also be proved by minimum counterexample. It was proved in Result 6.11 that \( 3 \mid (2^n - 1) \) for every nonnegative integer \( n \). We now give a proof of this result by minimum counterexample.

**Result 6.25**

For every nonnegative integer \( n \),

\[
3 \mid (2^n - 1).
\]

**Proof**

Assume, to the contrary, that there are nonnegative integers \( n \) for which \( 3 \nmid (2^n - 1) \). By Theorem 6.7, there is a smallest nonnegative integer \( n \) such that \( 3 \nmid (2^n - 1) \). Denote this integer by \( m \). Thus \( 3 \nmid (2^{2n} - 1) \) and \( 3 \nmid (2^n - 1) \) for all nonnegative integers \( n \) for which \( 0 \leq n < m \). Since \( 3 \mid (2^n - 1) \) when \( n = 0 \), it follows that \( m \geq 1 \). Hence, \( m \) can be expressed by \( m = k + 1 \), where \( 0 \leq k < m \). Thus, \( 3 \nmid (2^k - 1) \), which implies that \( 2^k - 1 = 3x \) for some integer \( x \). Consequently, \( 2^k = 3x + 1 \). Observe that

\[
2^{2m} - 1 = 2^{2(k+1)} - 1 = 2^{2k+2} - 1 = 2^2 \cdot 2^{2k} - 1
\]

\[
= 4(3x + 1) - 1 = 12x + 3 = 3(4x + 1).
\]

Since \( 4x + 1 \) is an integer, \( 3 \mid (2^{2m} - 1) \), which produces a contradiction.

Even though a proof by minimum counterexample is really a proof by contradiction, this has a close connection to an induction proof. While a proof by minimum counterexample occurs rarely in more elementary mathematics, it can be quite useful in more advanced mathematics. We give one additional example, a familiar one, using a proof by minimum counterexample.

**Result 6.26**

For every positive integer \( n \),

\[
1 + 2 + 3 + \cdots + n = \frac{n(n + 1)}{2}.
\]
Section 6.4 Exercises

Proof Assume, to the contrary, that

\[ 1 + 2 + 3 + \cdots + n \neq \frac{n(n + 1)}{2} \]

for some positive integers \( n \). By the Well-Ordering Principle, there is a smallest positive integer \( n \) such that

\[ 1 + 2 + 3 + \cdots + n \neq \frac{n(n + 1)}{2}. \]

Denote this integer by \( m \). Therefore,

\[ 1 + 2 + 3 + \cdots + m \neq \frac{m(m + 1)}{2}, \]

while

\[ 1 + 2 + 3 + \cdots + n = \frac{n(n + 1)}{2} \]

for every integer \( n \) with \( 1 \leq n < m \). Since \( 1 = 1(1 + 1)/2 \), it follows that \( m \geq 2 \). Hence, we can write \( m = k + 1 \), where \( 1 \leq k < m \). Consequently,

\[ 1 + 2 + 3 + \cdots + k = \frac{k(k + 1)}{2}. \]

Observe that

\[ 1 + 2 + 3 + \cdots + m = 1 + 2 + 3 + \cdots + (k + 1) = (1 + 2 + 3 + \cdots + k) + (k + 1) \]

\[ = \frac{k(k + 1)}{2} + (k + 1) = \frac{k(k + 1) + 2(k + 1)}{2} \]

\[ = \frac{(k + 1)(k + 2)}{2} = \frac{m(m + 1)}{2}, \]

which produces a contradiction. \( \blacksquare \)

SECTION 6.4 EXERCISES

6.40. Use the method of minimum counterexample to prove Result 6.23: If \( r \) is a nonzero real number such that \( r + \frac{1}{r} \) is an integer, then \( r^n + \frac{1}{r^n} \) is an integer for every positive integer \( n \).

6.41. Give a proof by minimum counterexample that \( 1 + 3 + 5 + \cdots + (2n - 1) = n^2 \) for every positive integer \( n \).

6.42. Prove that \( 5 \mid (n^5 - n) \) for every integer \( n \).

6.43. Use proof by minimum counterexample to prove that \( 3 \mid (2^n + 2^{n+1}) \) for every nonnegative integer \( n \).

6.44. Give a proof by minimum counterexample that \( 2^n > n^2 \) for every integer \( n \geq 5 \).

6.45. Prove that \( 12 \mid (n^4 - n^2) \) for every positive integer \( n \).

6.46. Let \( S = \{2^n : n \in \mathbb{Z}, n \geq 0\} \). Use proof by minimum counterexample to prove that for every \( n \in \mathbb{N} \), there exists a subset \( S_n \) of \( S \) such that \( \sum_{i \in S_n} i = n \).

6.47. Use proof by minimum counterexample to prove that \( 6 \mid 7n(n^2 - 1) \) for every positive integer \( n \).
Chapter 6 Supplemental Exercises

6.48. Prove that \(1 \cdot 2 + 2 \cdot 3 + 3 \cdot 4 + \cdots + n(n + 1) = \frac{n(n+1)(n+2)}{3}\) for every positive integer \(n\).

6.49. Prove that \(4^n > n^3\) for every positive integer \(n\).

6.50. Prove that \(24 \mid (5^{2n} - 1)\) for every positive integer \(n\).

6.51. By Result 6.5, \(1^2 + 2^2 + 3^2 + \cdots + n^2 = \frac{n(n+1)(2n+1)}{6}\) for every positive integer \(n\).

(a) Use (6.12) to determine a formula for \(2^2 + 4^2 + 6^2 + \cdots + (2n)^2\) for every positive integer \(n\).

(b) Use (6.12) and (a) to determine a formula for \(1^2 + 3^2 + 5^2 + \cdots + (2n-1)^2\) for every positive integer \(n\).

(c) Use (a) and (b) to determine a formula for \(1^2 - 2^2 + 3^2 - 4^2 + \cdots + (-1)^{n+1} n^2\) for every positive integer \(n\).

(d) Use mathematical induction to verify the formulas in (b) and (c).

6.52. Use the Strong Principle of Mathematical Induction to prove that for each integer \(n \geq 28\), there are nonnegative integers \(x\) and \(y\) such that \(n = 5x + 8y\).

6.53. Use the Principle of Mathematical Induction to show that there exists a positive integer \(m\) such that for each integer \(n \geq m\), there are positive integers \(x\) and \(y\) such that \(n = 3x + 5y\).

6.54. Use the Principle of Mathematical Induction to show that there exists a positive integer \(m\) such that for each integer \(n \geq m\), there are integers \(x, y \geq 2\) such that \(n = 2x + 3y\).

6.55. A sequence \(\{a_n\}\) of real numbers is defined recursively by \(a_1 = 1, a_2 = 2\) and \(a_n = \sum_{i=1}^{n-1} (i-1) a_i\) for \(n \geq 3\). Prove that \(a_n = (n-1)!\) for every integer \(n \geq 3\).

6.56. Consider the sequence \(a_1 = 2, a_2 = 5, a_3 = 9, a_4 = 14\), etc.

(a) Find a recurrence relation that expresses \(a_n\) in terms of \(a_{n-1}\) for every integer \(n \geq 2\).

(b) Conjecture an explicit formula for \(a_n\) and then prove that your conjecture is correct.

6.57. The following theorem allows one to prove certain quantified statements over some finite sets.

**The Principle of Finite Induction**

For a fixed positive integer \(m\), let \(S = \{1, 2, \ldots, m\}\). For each \(n \in S\), let \(P(n)\) be a statement. If

(a) \(P(1)\) is true and

(b) the implication

\[\text{If } P(k), \text{ then } P(k + 1).\]

is true for every integer \(k\) with \(1 \leq k < m\),
then \( P(n) \) is true for every integer \( n \in S \).

Use the Principle of Finite Induction to prove the following result.

Let \( S = \{1, 2, \ldots, 24\} \). For every integer \( t \) with \( 1 \leq t \leq 300 \), there exists a subset \( S_t \subseteq S \) such that \( \sum_{i \in S_t} i = t \).

6.58. Evaluate the proposed proof of the following result.

**Result**

For every positive integer \( n \),

\[
1 + 3 + 5 + \cdots + (2n - 1) = n^2.
\]

**Proof**

We proceed by induction. Since \( 2 \cdot 1 - 1 = 1^2 \), the formula holds for \( n = 1 \).

Assume that \( 1 + 3 + 5 + \cdots + (2k - 1) = k^2 \) for a positive integer \( k \). We prove that \( 1 + 3 + 5 + \cdots + (2k + 1) = (k + 1)^2 \). Observe that

\[
\begin{align*}
1 + 3 + 5 + \cdots + (2k + 1) &= (k + 1)^2 \\
1 + 3 + 5 + \cdots + (2k - 1) + (2k + 1) &= (k + 1)^2 \\
(2k - 1) + 1 &= (k + 1)^2 \\
(2k - 1) + 1 &= (k + 1)^2.
\end{align*}
\]

6.59. Below is given a proof of a result. Which result is being proved and which proof technique is being used?

**Proof**

Assume, to the contrary, that there is some positive integer \( n \) such that 8 \( \not| \) \( (3^{2n} - 1) \). Let \( m \) be the smallest positive integer such that 8 \( \not| \) \( (3^{2m} - 1) \). For \( n = 1 \), \( 3^{2n} - 1 = 8 \). Since 8 \( | \) 8, it follows that \( m \geq 2 \). Let \( m = k + 1 \). Since 1 \( \leq k < m \), it follows that 8 \( | \) \( (3^{2k} - 1) \). Therefore, \( 3^{2k} - 1 = 8x \) for some integer \( x \) and so \( 3^{2k} = 8x + 1 \). Hence,

\[
3^{2m} - 1 = 3^{2(k+1)} - 1 = 3^{2k+2} - 1 = 9 \cdot 3^{2k} - 1 \\
= 9(8x + 1) - 1 = 72x + 8 = 8(9x + 1).
\]

Since \( 9x + 1 \) is an integer, 8 \( | \) \( (3^{2m} - 1) \), which produces a contradiction.

6.60. Below is given a proof of a result. Which result is being proved and which proof technique is being used?

**Proof**

First observe that \( a_1 = 8 = 3 \cdot 1 + 5 \) and \( a_2 = 11 = 3 \cdot 2 + 5 \). Thus, \( a_n = 3n + 5 \) for \( n = 1 \) and \( n = 2 \). Assume that \( a_i = 3i + 5 \) for all integers \( i \) with \( 1 \leq i \leq k \), where \( k \geq 2 \). Since \( k + 1 \geq 3 \), it follows that

\[
\begin{align*}
a_{k+1} &= 5a_k - 4a_{k-1} - 9 = 5(3k + 5) - 4(3k + 2) - 9 \\
&= 15k + 25 - 12k - 8 - 9 = 3k + 8 = 3(k + 1) + 5.
\end{align*}
\]

6.61. By an \( n \)-gon, we mean an \( n \)-sided polygon. So, a 3-gon is a triangle and a 4-gon is a quadrilateral. It is well known that the sum of the interior angles of a triangle is \( 180^\circ \). Use induction to prove that for every integer \( n \geq 3 \), the sum of the interior angles of an \( n \)-gon is \( (n - 2) \cdot 180^\circ \).

6.62. Suppose that \( \{a_n\} \) is a sequence of real numbers defined recursively by \( a_1 = 1 \), \( a_2 = 2 \), \( a_3 = 3 \), and \( a_n = 2a_{n-1} - a_{n-3} \) for \( n \geq 4 \). Prove that \( a_n = a_{n-1} + a_{n-2} \) for every integer \( n \geq 3 \).
6.63. Suppose that \( \{a_n\} \) is a sequence of real numbers defined recursively by \( a_1 = 1 \), \( a_2 = 2 \) and \( a_n = a_{n-1}/a_{n-2} \) for \( n \geq 3 \).

(a) Prove that

\[
a_n = \begin{cases} 
1 & \text{if } n \equiv 1, 4 \pmod{6} \\
2 & \text{if } n \equiv 2, 3 \pmod{6} \\
1/2 & \text{if } n \equiv 0, 5 \pmod{6}
\end{cases}
\]

for every positive integer \( n \).

(b) Prove, for each nonnegative integer \( j \), that \( \sum_{i=1}^{6} a_{j+i} = 7 \).

6.64. Let \( x \in \mathbb{R} \) where \( x \geq 3 \). Prove that \( (1 + x)^n \geq \left[ \frac{n(n-1)(n-2)}{6} \right] x^3 \) for every integer \( n \geq 3 \).

6.65. Prove that \( \sum_{j=1}^{n} \left( \sum_{i=1}^{j} i \right) = \frac{n(n+1)(n+2)}{6} \) for every positive integer \( n \).

6.66. Prove that \( \sum_{j=1}^{n} \left( \sum_{i=1}^{j} (2i - 1) \right) = \frac{n(n+1)(2n+1)}{6} \) for every positive integer \( n \).

6.67. Prove that there exists an odd integer \( m \) such that every odd integer \( n \) with \( n \geq m \) can be expressed as \( 3a + 5b + 7c \) for positive integers \( a, b, \) and \( c \).

6.68. Since \( 2 \cdot 1 + 3 \cdot 1 + 5 \cdot 1 = 10 \), there exist three positive integers \( a, b, c \) such that \( 2a + 3b + 5c = 10 \).

(a) Prove that there do not exist three positive integers \( a, b, c \) such that \( 2a + 3b + 5c = 11 \).

(b) Use Mathematical Induction to prove for every integer \( n \geq 12 \), there exist three positive integers \( a, b, c \) such that \( 2a + 3b + 5c = n \).

6.69. Let \( \{a_n\} \) be a sequence of all rational numbers. For each rational number \( a_n \) \( (n \in \mathbb{N}) \), \( P(a_n) \) is a statement. Suppose that it is known that \( P(a_1) \) is a true statement and that whenever \( P(a_k) \) is a true statement for an arbitrary rational number \( a_k \), then \( P(a_{k+1}) \) is a true statement for the rational number \( a_{k+1} \). Is \( P(a_n) \) true for every rational number \( a_n \)?

6.70. (a) Compute each of the numbers \( \frac{1}{13} + \frac{1}{37}, \frac{1}{13} + \frac{1}{59}, \frac{1}{13} + \frac{1}{73}, \frac{1}{37} + \frac{1}{59}, \frac{1}{37} + \frac{1}{73}, \frac{1}{59} + \frac{1}{73} \).

(b) Based on your answers in (a), give a conjecture for a simplified formula for \( \frac{1}{13} + \frac{1}{37} + \frac{1}{59} + \cdots + \frac{1}{(2n-1)(2n+1)} \) for every positive integer \( n \).

(c) Use the Principle of Mathematical Induction to verify your conjecture in (b).

6.71. Let \( S = 2 + 7 + 12 + \cdots + (5n - 3) \) where \( n \in \mathbb{N} \).

(a) Write \( S \) as \( (5n - 3) + (5n - 8) + \cdots + 7 + 2 \) to obtain a formula for \( S \).

(b) Use the Principle of Mathematical Induction to verify your formula for \( S \) obtained in (a).

6.72. (a) Since \( (3, 4, 5) \) is a Pythagorean triple, \( 3^2 + 4^2 = 5^2 = 25 \). What is the value of \( (30)^2 + (40)^2 \)?

(b) Show that there are distinct positive integers \( a \) and \( b \) such that \( (1) a^2 + b^2 = 10, (2) a^2 + b^2 = 10^2 \) and \( (3) a^2 + b^2 = 10^3 \).

(c) Use the Principle of Mathematical Induction to prove for every positive integer \( n \) that there exist distinct positive integers \( a \) and \( b \) such that \( a^2 + b^2 = 10^n \).

6.73. We saw in Result 4.6(a) that if \( x \) is an integer such that \( 3 \mid x \), then \( 3 \mid (x^2 - 1) \). In particular, if \( x \equiv 1 \pmod{3} \), then \( x^2 \equiv 1 \pmod{3} \). Use the method of minimum counterexample to prove that if \( x \) is a positive integer such that \( x \equiv 1 \pmod{6} \), then \( x^3 \equiv 1 \pmod{18} \).
7

Reviewing Proof Techniques

Now that you have been introduced to the proof techniques described in Chapters 3–6, it is appropriate to review these techniques once more to be certain that you have a clear understanding of them. Of course, it’s important not only that you understand these techniques but know how and when to use them.

The examples that we have provided to illustrate these techniques have, for the most part, involved properties of numbers (integers, rational numbers and real numbers) and sets. Where you will encounter these techniques in the future will likely be in more advanced courses such as abstract algebra, number theory and advanced calculus and possibly in courses such as combinatorics and topology. It is not unusual for you to be expected to read and understand a proof of a statement or to perform the more challenging task of verifying the truth of a statement yourself. This is part of the reason you have been learning and applying the various proof techniques presented in Chapters 3–6. You need to know what constitutes a proof.

When faced with a statement whose truth is to be verified, there are several questions to be asked before attempting to give a proof. First, do you have a clear understanding of the statement? Do you know the definitions of all mathematical concepts mentioned in the statement? What properties of these concepts and related results do you know? If you’re not certain or don’t recall them, then this should be reviewed. Is it clear what information you are permitted to use in an attempt to verify the statement? A proof of a statement will be of no value if it can’t be understood. Consequently, any proof must be carefully and clearly written so that a well-prepared student will be convinced that the statement is true.

Often, the way that a statement is worded will suggest a proof technique that may be successful. Typically, the first technique to try is a direct proof. If it appears that you’re not having success with a direct proof, then you need to determine whether another approach might work.

It is easy to become frustrated when you’re trying to verify a statement. We all go through this. It’s part of the learning process. Taking a single course dealing with mathematical proofs will not make you an expert on proofs. You need added practice in what you have learned so far. After taking a course dealing with mathematical proofs, you might find a professor in a follow-up course disappointed that the students are having difficulty proving theorems in the course. Indeed, you might be disappointed with
Chapter 7

Reviewing Proof Techniques

yourself because of the difficulty you are having. However, expectations you and your professor have should not be too high. Having said this though, you should know and should recall the various proof techniques and how these are applied to verify statements. When you are taking a new course, you have different concepts to understand and it takes some time (and study) to get a feeling for these.

As you gain more experience, you might find yourself thinking of questions that a given exercise suggests and then trying to answer your own questions. While we will encounter this sort of thing in the next chapter, let’s get to the main point of this chapter, namely to review the proof techniques we’ve already introduced and see how they can be used to verify statements.

7.1 REVIEWING DIRECT PROOF AND PROOF BY CONTRAPOSITIVE

Let’s first review the two proof techniques direct proof and proof by contrapositive, which were discussed in Chapters 3 and 4. Here we have two open sentences $P(x)$ and $Q(x)$ defined over some domain $S$. That is, for each $x \in S$, both $P(x)$ and $Q(x)$ are statements. What we’re interested in is verifying the implication

$$\forall x \in S, \ P(x) \Rightarrow Q(x): \text{Let } x \in S. \text{ If } P(x), \text{ then } Q(x).$$

To give a direct proof of this quantified statement, we assume that $P(x)$ is true for an arbitrary element $x \in S$ and attempt to show that $Q(x)$ is true for this element $x$. The direct proof is the most common and most used proof technique. Typically, a direct proof is used when the assumption that $P(x)$ is true provides us with sufficient information to show that $Q(x)$ is true.

We have seen that the contrapositive of a given implication is logically equivalent to the implication. Consequently, if the implication (7.2) below

$$\forall x \in S, \sim Q(x) \Rightarrow \sim P(x): \text{Let } x \in S. \text{ If not } Q(x), \text{ then not } P(x),$$

which is the contrapositive of the implication in (7.1), can be verified, then the implication in (7.1) is verified. In a proof by contrapositive then, we assume that $Q(x)$ is false for an arbitrary element $x \in S$ and attempt to show that $P(x)$ is false for such an element $x$. Typically, one thinks of using a proof by contrapositive rather than a direct proof if it appears more useful to assume that $Q(x)$ is false and thereby show that $P(x)$ is false rather than assume that $P(x)$ is true and attempt to show that $Q(x)$ is true.

Many results encountered involve biconditionals:

$$\forall x \in S, \ P(x) \Leftrightarrow Q(x): \text{Let } x \in S. \text{ Then } P(x) \text{ if and only if } Q(x).$$

In this case, a proof consists of proving both the implication in (7.1) as well as its converse stated in (7.3):

$$\forall x \in S, \ Q(x) \Rightarrow P(x).$$

It’s not unusual in a proof of a biconditional to use both a direct proof and a proof by contrapositive. Let’s consider the following example.

**Result to Prove** Let $n \in \mathbb{Z}$. Then $3n^4 + 7$ is odd if and only if $n$ is even.
The phrase “if and only if” in the wording of this result tells us that this result is a biconditional and can therefore be expressed symbolically as
\[ \forall n \in \mathbb{Z}, P(n) \leftrightarrow Q(n), \]
where
- \( P(n) \): \( 3n^4 + 7 \) is odd and \( n \) is even.
- \( Q(n) \): \( n \) is even.

Therefore, to prove this result we need to verify the following two implications for an integer \( n \):
- \( P(n) \Rightarrow Q(n) \): If \( 3n^4 + 7 \) is odd, then \( n \) is even.
- \( Q(n) \Rightarrow P(n) \): If \( n \) is even, then \( 3n^4 + 7 \) is odd.

Let’s see then how we might prove this result.

**PROOF STRATEGY**

The order in which we prove these two implications doesn’t matter. Proving the implication “If \( n \) is even, then \( 3n^4 + 7 \) is odd,” seems quite straightforward. We use a direct proof. Consequently, we assume that \( n \) is an even integer and so \( n = 2x \) for some integer \( x \). Substituting \( n = 2x \) for \( n \) in \( 3n^4 + 7 \) and showing that we can express this as \( 2z + 1 \) for some integer \( z \) will verify the implication. To verify the converse “If \( 3n^4 + 7 \) is odd, then \( n \) is even,” it is appropriate to use a proof by contrapositive, where the contrapositive of this implication is then “If \( n \) is odd, then \( 3n^4 + 7 \) is even.” Here it appears that we need to assume that \( n \) is odd and so \( n = 2y + 1 \) for some integer \( y \). This gives us
\[
3n^4 + 7 = 3(2y + 1)^4 + 7 = 3(16y^4 + 32y^3 + 24y^2 + 8y + 1) + 7 \\
= 48y^4 + 96y^3 + 72y^2 + 24y + 10 = 2(24y^4 + 48y^3 + 36y^2 + 12y + 5).
\]

Since \( 24y^4 + 48y^3 + 36y^2 + 12y + 5 \) is an integer, \( 3n^4 + 7 \) is even.

Although this approach results in a correct proof of the converse, the main difficulty may be in the step that requires us to expand \((2y + 1)^4\). It’s quite possible that we can’t recall how this is done and a mistake is made. Therefore, we might wonder if there is a simpler way to handle this step. In this particular part of this proof, we have assumed that \( n \) is odd and we are trying to show that \( 3n^4 + 7 \) is even. Here it would be useful to recall Theorem 3.12 or, better yet, the equivalent formulation of this theorem in (3.4):

Let \( x \in \mathbb{Z} \). Then \( x^2 \) is odd if and only if \( x \) is odd.

Of course, in our case, the odd integer is being denoted by \( n \). By (3.4), \( n^2 \) is odd, as is \((n^2)^2 = n^4\). So, we can provide a different (and simpler) proof of the converse mentioned above.

**Result 7.1**

Let \( n \in \mathbb{Z} \). Then \( 3n^4 + 7 \) is odd if and only if \( n \) is even.

**Proof**

Assume first that \( n \) is even. Then \( n = 2x \) for some integer \( x \). Therefore,
\[
3n^4 + 7 = 3(2x)^4 + 7 = 48x^4 + 7 = 2(24x^4 + 3) + 1.
\]

Since \( 24x^4 + 3 \) is an integer, \( 3n^4 + 7 \) is odd.

For the converse, assume that \( n \) is odd. Applying Theorem 3.12 twice, we have that \( n^2 \) and \((n^2)^2 = n^4\) are both odd. So \( n^4 = 2y + 1 \) for some integer \( y \). Hence,
\[
3n^4 + 7 = 3(2y + 1) + 7 = 6y + 10 = 2(3y + 5).
\]

Since \( 3y + 5 \) is an integer, \( 3n^4 + 7 \) is even.

\[ \Box \]
Chapter 7  Reviewing Proof Techniques

There are occasions when knowing that an element $x$ belongs to a certain set $S$ is not sufficiently useful to prove a given statement. However, it may occur that there is a partition $\{S_1, S_2\}$ of $S$ into two (or possibly more) subsets of $S$ such that knowing $x \in S_1$ or $x \in S_2$ provides us with more information that allows us to give a proof. This approach is a proof by cases. Let’s consider an example that illustrates this.

**Result to Prove**  Let $a, b \in \mathbb{Z}$. Then $3 \mid (5a + 8b)$ if and only if $3 \mid (a + b)$.

Once again, we have a biconditional to verify, which consists of verifying the two implications:

- If $3 \mid (5a + 8b)$, then $3 \mid (a + b)$.
- If $3 \mid (a + b)$, then $3 \mid (5a + 8b)$.

Let’s look at how we might do this.

**Proof Strategy**  To verify the second implication “If $3 \mid (a + b)$, then $3 \mid (5a + 8b)$.”, it seems reasonable to use a direct proof, where we would begin by assuming that $3 \mid (a + b)$, which implies that $a + b = 3c$ for some integer $c$ and so $b = 3c - a$. Our goal is to show that $5a + 8b$ can be written as $3d$ for some integer $d$. To verify the converse, “If $3 \mid (5a + 8b)$, then $3 \mid (a + b)$.”, it appears that a proof by contrapositive should be used, resulting in a direct proof of the following:

- If $3 \nmid (a + b)$, then $3 \nmid (5a + 8b)$.

After assuming that $3 \nmid (a + b)$, we know that either $a + b = 3q + 1$ or $a + b = 3q + 2$ for some integer $q$. Let’s see how this works.

**Result 7.2**  Let $a, b \in \mathbb{Z}$. Then $3 \mid (5a + 8b)$ if and only if $3 \mid (a + b)$.

**Proof**  Assume first that $3 \mid (a + b)$. Then $a + b = 3c$ for some integer $c$. Thus, $b = 3c - a$ and

$$5a + 8b = 5a + 8(3c - a) = 5a + 24c - 8a = 24c - 3a = 3(8c - a).$$

Since $8c - a$ is an integer, $3 \mid (5a + 8b)$.

For the converse, assume that $3 \nmid (a + b)$. Therefore, either $a + b = 3q + 1$ or $a + b = 3q + 2$ for some integer $q$. We consider these two cases.

**Case 1.** $a + b = 3q + 1$, where $q \in \mathbb{Z}$. Thus, $b = 3q + 1 - a$. Then

$$5a + 8b = 5a + 8(3q + 1 - a) = 5a + 24q + 8 - 8a = 24q - 3a + 8 = 3(8q - a + 2) + 2.$$  

Since $8q - a + 2$ is an integer, $3 \mid (5a + 8b)$.

**Case 2.** $a + b = 3q + 2$, where $q \in \mathbb{Z}$. Thus, $b = 3q + 2 - a$. Then

$$5a + 8b = 5a + 8(3q + 2 - a) = 5a + 24q + 16 - 8a = 24q - 3a + 16 = 3(8q - a + 5) + 1.$$  

Since $8q - a + 5$ is an integer, $3 \mid (5a + 8b)$. 

$\blacksquare$
Although the proof of Result 7.2 appeared to work well, it may be a good idea to look at what we're trying to prove once more to see if there may be a simper, clearer way to do this.

**PROOF ANALYSIS**

In the proof of the implication “If $3 \mid (a + b)$, then $3 \mid (5a + 8b)$.” we have $a + b = 3c$ where $c \in \mathbb{Z}$. Perhaps, this can be done more simply by noticing that $5a + 8b = 5(a + b) + 3b = 5(3q) + 3b = 3(5q + b)$. ♦

**Alternate Proof of Result 7.2**

Assume that $3 \mid (a + b)$. Then $a + b = 3q$ for some integer $q$.

Then
\[ 5a + 8b = (5a + 5b) + 3b = 5(a + b) + 3b = 5(3q) + 3b = 3(5q + b). \]

Since $5q + b$ is an integer, $3 \mid (5a + 8b)$.

For the converse, assume that $3 \nmid (a + b)$. Therefore, either $a + b = 3q + 1$ or $a + b = 3q + 2$ for some integer $q$. We consider these two cases.

**Case 1.** $a + b = 3q + 1$, where $q \in \mathbb{Z}$. Then
\[ 5a + 8b = 5(a + b) + 3b = 5(3q + 1) + 3b = 3(5q + b + 1) + 2. \]

Since $5q + b + 1$ is an integer, $3 \nmid (5a + 8b)$.

**Case 2.** $a + b = 3q + 2$, where $q \in \mathbb{Z}$. Then
\[ 5a + 8b = 5(a + b) + 3b = 5(3q + 2) + 3b = 3(5q + b + 3) + 1. \]

Since $5q + b + 3$ is an integer, $3 \nmid (5a + 8b)$. ■

**PROOF ANALYSIS**

Another alternate proof of Result 7.2 can be given by attempting a direct proof of “If $3 \mid (5a + 8b)$, then $3 \mid (a + b)$.” If we first assume that $3 \mid (5a + 8b)$, then $5a + 8b = 3x$ for some $x \in \mathbb{Z}$. Then observing that
\[ a + b = 6a + 9b - (5a + 8b) = 6a + 9b - 3x = 3(2a + 3b - x), \]

we have $3 \mid (a + b)$. ♦

### 7.2 REVIEWING PROOF BY CONTRADICTION AND EXISTENCE PROOFS

Another useful proof technique that we discussed in Chapter 5 is **proof by contradiction**, which is especially helpful when we are attempting to prove a negative-sounding result. In such a situation, we assume, for an open sentence $R(x)$ defined over a domain $S$, that the statement $\forall x \in S, R(x)$ is false, which implies that the statement $\exists x \in S, \sim R(x)$ is true, that is, there exists some element $x \in S$ such that $R(x)$ is false. If $R(x)$ can be expressed as an implication $P(x) \Rightarrow Q(x)$, then $\sim R(x)$ can be expressed as $P(x) \land (\sim Q(x))$. Hence, to prove the statement $\forall x \in S, P(x) \Rightarrow Q(x)$ by contradiction, we assume that there is some element $x \in S$ such that $P(x)$ is true and $Q(x)$ is false and attempt to obtain a contradiction. Consider the following example.
Chapter 7  Reviewing Proof Techniques

Result to Prove There is no real number \( x \) such that \( x + \frac{1}{x} = 1 \).

Proof Strategy Since this result is negative-sounding, this suggests trying a proof by contradiction, where we would begin with: Assume, to the contrary, that there is a real number \( x \) such that \( x + \frac{1}{x} = 1 \). Now we must determine how to obtain a contradiction. Certainly, \( x \neq 0 \), for otherwise \( \frac{1}{x} \) is not defined. One possibility would be to proceed by considering various cases for \( x \), say \( x < 0 \), \( x \geq 1 \) and \( 0 < x < 1 \), for example. Notice that if \( x < 0 \), then \( x + \frac{1}{x} < 0 \); if \( x \geq 1 \), then \( x + \frac{1}{x} > 1 \); and if \( 0 < x < 1 \), then \( \frac{1}{x} > 1 \) and so \( x + \frac{1}{x} > 1 \). Therefore, we arrive at a contradiction in each of these cases. On the other hand, since \( x + \frac{1}{x} = 1 \), this might suggest attempting a proof that involves solving this equation.

Result 7.3 There is no real number \( x \) such that \( x + \frac{1}{x} = 1 \).

Proof Assume, to the contrary, that there exists a real number \( x \) such that \( x + \frac{1}{x} = 1 \). So \( x \neq 0 \). Multiplying this equation by \( x \), we obtain \( x^2 + 1 = x^2 + x + 1 = 0 \). By the quadratic formula, the solutions to this equation are

\[
x = \frac{1 \pm \sqrt{1 - 4 \cdot 1 \cdot 1}}{2} = \frac{1 \pm \sqrt{-3}}{2}.\]

Since \( x \) is not a real number, the equation \( x + \frac{1}{x} = 1 \) has no real number solution, which is a contradiction.

Proof Analysis There are occasions when considering a certain statement (whether the statement is true or false) suggests a question of whether a related statement may be true. It is always good to be inquisitive. For example, we now know that there is no real number \( x \) such that \( x + \frac{1}{x} = 1 \). If \( x = 1 \), then \( x + \frac{1}{x} = 2 \); that is, there does exist a real number \( x \) such that \( x + \frac{1}{x} = 2 \). This brings up another question: For which real numbers \( c \), does there exist a real number \( x \) such that \( x + \frac{1}{x} = c \) or, equivalently, \( x^2 + 1 = cx \)? Using the quadratic formula to solve the equation \( x^2 - cx + 1 = 0 \), we have

\[
x = \frac{c \pm \sqrt{c^2 - 4}}{2}.
\]

Therefore, this equation has a real number solution only when \( c^2 \geq 4 \), that is, when \( c \geq 2 \) or \( c \leq -2 \).

The discussion above provides a proof of the following statement: For every real number \( c \) with \( |c| \geq 2 \), there is a real number solution of the equation

\[
x + \frac{1}{x} = c.
\]
In fact, for \( c \in \mathbb{R} \), the equation (7.4) has a real number solution if and only if \(|c| \geq 2\).

Proofs of the statements \( \exists x \in S, P(x) \) are existence proofs, also discussed in Chapter 5. Such a proof can be given either by exhibiting an element \( s \in S \) such that \( P(s) \) is true or perhaps showing that such an element \( s \) must exist even if we can’t actually provide a specific element. Let’s look at examples of existence proofs.

**Result 7.4** There exist positive integers \( a \) and \( b \) such that \( a + b = ab \).

**Proof** Observe that if \( a = b = 2 \), then \( a + b = ab \).

**PROOF ANALYSIS** The question here is how one discovered this proof, that is, thought of values of \( a \) and \( b \). While it may have been simple enough to think of these values, we are interested in solving \( a + b = ab \) for positive integers \( a \) and \( b \). Thus, \( ab - a - b = 0 \). Adding 1 to both sides, we have \( ab - a - b + 1 = 1 \) and so \((a - 1)(b - 1) = 1\). Clearly, \( a, b \geq 2 \). Thus, \( a - 1 = 1 \) and \( b - 1 = 1 \); hence, \( a = b = 2 \) and the example given in the proof is the only example.

**Result 7.5** There exists a positive real number \( r \) such that \( r^2 \) lies between \( r \) and \( r^3 \).

**Proof** Observe that if \( r = 2 \), then \( r^2 = 4 \) and \( r^3 = 8 \) and so \( r < r^2 < r^3 \).

**PROOF ANALYSIS** A proof of this result consists of searching for a number satisfying the given condition. It turns out that the fact that \( r = 2 \) satisfies the condition is not surprising. Since we want \( r^2 \) to lie between \( r \) and \( r^3 \), we have either (1) \( r < r^2 < r^3 \) or (2) \( r^3 < r^2 < r \). If we divide by the positive real number \( r \), we have either (1) \( 1 < r < r^2 \) or (2) \( r^2 < r < 1 \). Thus, any positive real number different from 1 serves as a proof of the statement.

**Result 7.6** There exists a 9-digit integer \( n \) consisting of the nine digits 0, 1, \ldots, 8 such that \( k \mid n \) for each integer \( k \) in the 9-element set \( \{2, 3, \ldots, 10\} \).

**Proof** The integer \( n = 638, 157, 240 \) has the desired property.

**PROOF ANALYSIS** Finding such a number \( n \) in this proof requires experimenting with the divisibility requirements.

In the existence proof below, it is shown that an example exists without actually specifying one.

**Result 7.7** There exists a real number solution to the equation \( x^8 - 3x^5 + 1 = 0 \).

**Proof** The equation \( p(x) = x^8 - 3x^5 + 1 = 0 \) is a polynomial equation. Since \( p(0) = 1 \) and \( p(1) = -1 \) and every polynomial is continuous, it follows by the Intermediate Value Theorem that there exists a real number solution \( r \in (0, 1) \) such that \( p(r) = 0 \).
In Chapter 6, we saw that proof by induction is an especially useful proof technique when the domain \( S \) is the set \( \mathbb{N} \) of positive integers (or a closely related set). More specifically, suppose that we wish to prove a statement of the type

\[
\forall n \in \mathbb{N}, \ P(n).
\]

To prove such a statement by mathematical induction, we need to verify (1) that the statement \( P(1) \) is true and (2) that the implication \( \forall k \in \mathbb{N}, \ P(k) \Rightarrow P(k+1) \) is true. Step (1) is referred to as the basis step and Step (2) as the inductive step. Here, we are using the Principle of Mathematical Induction to prove this statement. Let’s now look at an example.

**Result to Prove**

Let \( n \) be a positive integer. If \( a_1, a_2, \ldots, a_n \) are \( n \) integers such that \( a_i \equiv 2 \pmod{3} \) for each integer \( i \) with \( 1 \leq i \leq n \), then \( a_1a_2 \cdots a_n \equiv 1 \pmod{3} \) if \( n \) is even and \( a_1a_2 \cdots a_n \equiv 2 \pmod{3} \) if \( n \) is odd.

**Proof Strategy**

Let’s first be certain that we understand what we need to prove. For each integer \( a_i \), we know that \( a_i \equiv 2 \pmod{3} \). Examples of such integers are 2, 5, 8 and 11. So, \( a_1 \equiv 2 \pmod{3} \). Since 1 is odd, the statement is true if \( n = 1 \). Suppose that \( n = 2 \). Then we need to show that \( a_1a_2 \equiv 1 \pmod{3} \). Since \( a_1 \equiv 2 \pmod{3} \) and \( a_2 \equiv 2 \pmod{3} \), it follows that \( a_1 = 3x + 2 \) and \( a_2 = 3y + 2 \) for integers \( x \) and \( y \) and so

\[
a_1a_2 = (3x + 2)(3y + 2) = 9xy + 6x + 6y + 4
\]

\[
= 3(3xy + 2x + 2y + 1) + 1.
\]

Since \( 3xy + 2x + 2y + 1 \) is an integer, \( a_1a_2 \equiv 1 \pmod{3} \). Because we are required to prove the statement is true for every integer \( n \), an induction proof looks plausible.

**Result 7.8**

For each positive integer \( n \), let \( a_1, a_2, \ldots, a_n \) be \( n \) integers such that \( a_i \equiv 2 \pmod{3} \) for each integer \( i \) with \( 1 \leq i \leq n \). Then \( a_1a_2 \cdots a_n \equiv 1 \pmod{3} \) if \( n \) is even and \( a_1a_2 \cdots a_n \equiv 2 \pmod{3} \) if \( n \) is odd.

**Proof**

We proceed by induction. Since \( a_1 \equiv 2 \pmod{3} \), the statement is true if \( n = 1 \). Assume that the statement is true for an arbitrary positive integer \( k \). We show that it’s true for \( k + 1 \). We consider two cases.

**Case 1. \( k \) is even.** By assumption, \( a_1a_2 \cdots a_k \equiv 1 \pmod{3} \). Thus, \( a_1a_2 \cdots a_k = 3x + 1 \) for some integer \( x \). Since \( a_{k+1} \equiv 2 \pmod{3} \), it follows that \( a_{k+1} = 3y + 2 \) for some integer \( y \). Therefore,

\[
a_1a_2 \cdots a_{k+1} = (a_1a_2 \cdots a_k)a_{k+1} = (3x + 1)(3y + 2)
\]

\[
= 9xy + 6x + 3y + 2 = 3(3xy + 2x + y + 2).
\]

Since \( 3xy + 2x + y + 2 \) is an integer, \( a_1a_2 \cdots a_{k+1} \equiv 2 \pmod{3} \).

**Case 2. \( k \) is odd.** By assumption, \( a_1a_2 \cdots a_k \equiv 2 \pmod{3} \). Thus, \( a_1a_2 \cdots a_k = 3w + 2 \) for some integer \( w \). Since \( a_{k+1} \equiv 2 \pmod{3} \), it follows that \( a_{k+1} = 3z + 2 \) for
7.4 Reviewing Evaluations of Proposed Proofs

Some integer \( z \). Therefore,

\[ a_1a_2 \cdots a_{k+1} = (a_1a_2 \cdots a_k)a_{k+1} = (3w + 2)(3z + 2) = 9wz + 6w + 6z + 4 = 3(3wz + 2w + 2z + 1) + 1. \]

Since \( 3wz + 2w + 2z + 1 \) is an integer, \( a_1a_2 \cdots a_{k+1} \equiv 1 \pmod{3} \).

The result then follows by the Principle of Mathematical Induction.

There are occasions when an attempt to verify the inductive step (2) in an induction proof may fail because assuming that \( P(k) \) is true does not provide sufficient information to show that \( P(k + 1) \) is true. In this case, there is another induction principle, called the **Strong Principle of Mathematical Induction**, that might be an appropriate approach to verify the given statement. In this case, to prove

\[ \forall n \in \mathbb{N}, \ P(n), \]

we need to verify the basis step (1) that the statement \( P(1) \) is true and the new inductive step (2) that the implication \( \forall k \in \mathbb{N}, \ P(1) \wedge P(2) \wedge \cdots \wedge P(k) \Rightarrow P(k+1) \) is true. Let’s see an example of this. First, we look at a famous sequence of integers that appears in Exercise 6.36. The sequence \( F_1, F_2, F_3, \ldots \) of integers defined by \( F_1 = F_2 = 1 \) and \( F_n = F_{n-1} + F_{n-2} \) for \( n \geq 3 \) is called the **Fibonacci sequence**. Therefore, \( F_1 = F_2 = 1, \ F_3 = 2, F_4 = 3, F_5 = 5 \) and \( F_6 = 8 \).

**Result 7.9**

Let \( r \) be a positive real number. The sequence \( a_1, a_2, a_3, \ldots \) of real numbers is defined by \( a_1 = a_2 = r \) and \( a_n = a_{n-1}a_{n-2} \) for \( n \geq 3 \). Then \( a_n = r^{F_n} \) for each \( n \in \mathbb{N} \).

**Proof**

We use the Strong Principle of Mathematical Induction. Since \( a_1 = r = r^1 = r^{F_1} \), the formula holds for \( n = 1 \). Assume for a positive integer \( k \), that \( a_i = r^{F_i} \) for every integer \( i \) with \( 1 \leq i \leq k \). We show that \( a_{k+1} = r^{F_{k+1}} \).

We consider two cases.

*Case 1. \( k = 1 \).* Then \( k + 1 = 2 \) and \( a_2 = r = r^1 = r^{F_1} \). Hence, \( (7.5) \) holds for \( k = 1 \).

*Case 2. \( k \geq 2 \).* Since \( k + 1 \geq 3 \), it follows that

\[ a_{k+1} = a_ka_{k-1} = r^{F_k}r^{F_{k-1}} = r^{F_k+F_{k-1}} = r^{F_{k+1}}. \]

Hence, \( (7.5) \) also holds for \( k \geq 2 \). By the Strong Principle of Mathematical Induction, \( a_n = r^{F_n} \) for every positive integer \( n \).

7.4 REVIEWING EVALUATIONS OF PROPOSED PROOFS

There are numerous types of errors that are often made when attempting to give a proof of a mathematical statement. For example, there can be mistakes in the logic of a proof technique, mistakes in the knowledge of the concepts used, as well as computational or algebraic mistakes. As we did in Section 3.5, let’s evaluate some proposed proofs of a few statements.
Chapter 7  Reviewing Proof Techniques

Example 7.10  Evaluate the proposed proof of the following statement.

If \( x \) is an integer such that \( 5x - 7 \) is even, then \( x \) is odd.

**Proof**  First, assume that \( x \) is even. Then \( x = 2a \) for some integer \( a \). Hence,

\[
5x - 7 = 5(2a) - 7 = 10a - 7 = 2(5a - 4) + 1.
\]

Since \( 5a - 4 \) is an integer, \( 5x - 7 \) is odd.

Next, assume that \( x \) is odd. Then \( x = 2b + 1 \) for some integer \( b \). Therefore,

\[
5x - 7 = 5(2b + 1) - 7 = 10b - 2 = 2(5b - 1).
\]

Since \( 5b - 1 \) is an integer, \( 5x - 7 \) is even.

**Proof Evaluation**  If this “proof” had ended after the statement “Since \( 5a - 4 \) is an integer, \( 5x - 7 \) is odd,” then the proof would be complete and correct. However, by adding the paragraph following this, a proof is given of the the following biconditional:

An integer \( x \) is odd if and only if \( 5x - 7 \) is even.

This is not what Example 7.10 states. This “proof” makes it appear that its author is not aware of what is required to prove this statement.

For an integer \( n \geq 2 \), the symbol \( \binom{n}{2} \), often read as “\( n \) choose 2,” denotes the number of 2-element subsets of an \( n \)-element set. It turns out that \( \binom{n}{2} = n(n - 1)/2 \). (This symbol will be encountered often in Chapter 13.)

Example 7.11  Evaluate the proposed proof of the following statement.

If \( n \) is an integer with \( n > 7 \), then \( \binom{n}{2} - (n - 1) > 3n - 6 \).

**Proof**  Observe that

\[
\binom{n}{2} - (n - 1) = \frac{n(n - 1)}{2} - (n - 1) > 3n - 6
\]

and so

\[
\frac{n(n - 1) - 2(n - 1)}{2} > 3n - 6.
\]

Therefore,

\[
n(n - 1) - 2(n - 1) > 6n - 12 = 6(n - 2).
\]

Hence,

\[(n - 2)(n - 1) > 6(n - 2).
\]

Dividing by \( n - 2 \), we obtain \( n - 1 > 6 \) or \( n > 7 \).
**7.4 Reviewing Evaluations of Proposed Proofs**

The problem here is that the “proof” begins with \( \binom{n}{2} - (n - 1) > 3n - 6 \), which we don’t know to be true, and concludes by showing that \( n > 7 \), which is part of the hypothesis. The information above can be used, however, to give a correct proof of the statement in Example 7.11 as follows:

Since \( n > 7 \), it follows that \( n - 1 > 6 \) and so \( n - 2 > 0 \). Multiplying the inequality \( n - 1 > 6 \) by \( n - 2 \), we have

\[
(n - 2)(n - 1) > 6(n - 2).
\]

Hence,

\[
n(n - 1) - 2(n - 1) > 6n - 12.
\]

Dividing by 2, we obtain \( \binom{n}{2} - (n - 1) > 3n - 6 \). ♦

**Example 7.12** Evaluate the proposed proof of the following statement.

There exists an odd integer \( x > 5 \) such that \( 3 \mid (5x - 1) \).

**Proof** Let \( x = 6a + 5 \) for some positive integer \( a \). Since \( x = 6a + 5 = 2(3a + 2) + 1 \) and \( 3a + 2 \) is an integer, it follows that \( x \) is odd. Because

\[
5x - 1 = 5(6a + 5) - 1 = 30a + 24 = 3(10a + 8)
\]

and \( 10a + 8 \) is an integer, it follows that \( 3 \mid (5x - 1) \). ■

**Proof Evaluation** In a certain sense, this “proof” is correct. However, to verify the statement in Example 7.12, all one needs is a single odd integer \( x > 5 \) for which \( 3 \mid (5x - 1) \). The integer \( x = 11 \) has the property that \( 5x - 1 = 5(11) - 1 = 54 = 3(18) \) and so \( x = 11 \) is such an integer. ♦

**Example 7.13** Evaluate the proof of the following statement.

For an integer \( x \), \( 3 \mid (8x + 1) \) if and only if \( x = 3q + 1 \) for some integer \( q \). \hspace{1cm} (7.6)

**Proof** We consider two cases.

1. **Case 1.** \( x = 3q + 1 \) for some integer \( q \). Then

\[
8x + 1 = 8(3q + 1) + 1 = 24q + 9 = 3(8q + 3).
\]

Since \( 8q + 3 \) is an integer, it follows that \( 3 \mid (8x + 1) \).

2. **Case 2.** There is no integer \( q \) such that \( x = 3q + 1 \). Therefore, either \( x = 3q \) for some integer \( q \) or \( x = 3q + 2 \) for some integer \( q \). We consider these two subcases.

   **Subcase 2.1.** \( x = 3q \) for some integer \( q \). Then

\[
8x + 1 = 8(3q) + 1 = 24q + 1 = 3(8q + 1).
\]

Since \( 8q + 1 \) is an integer, it follows that \( 3 \mid (8x + 1) \).

   **Subcase 2.2.** \( x = 3q + 2 \) for some integer \( q \). Then

\[
8x + 1 = 8(3q + 2) + 1 = 24q + 17 = 3(8q + 5) + 2.
\]

Since \( 8q + 5 \) is an integer, it follows that \( 3 \mid (8x + 1) \). ■
Chapter 7  Reviewing Proof Techniques

Proof Evaluation Since the statement is a biconditional, a proof of this statement should not be by cases. Instead, one needs to prove the following two implications:

If \( x = 3q + 1 \) for some integer \( q \), then \( 3 \mid (8x + 1) \).  \hspace{1cm} (7.7)

and

If \( 3 \mid (8x + 1) \), then \( x = 3q + 1 \) for some integer \( q \).  \hspace{1cm} (7.8)

Although the necessary information is presented in the proposed proof, the logic is incorrect. We can begin a correct proof as follows: First, assume that \( x = 3q + 1 \) for some integer \( q \). We can then proceed as above to verify implication (7.7). We can then say the following: For the converse, assume that there is no integer \( q \) such that \( x = 3q + 1 \). We can then verify implication (7.8) using two cases: Case 1. \( x = 3q \) for some integer \( q \). and Case 2. \( x = 3q + 2 \) for some integer \( q \). We can then proceed as above to obtain a correct proof of the statement (7.6).

Example 7.14 Evaluate the proposed proof of the following statement.

For every nonnegative integer \( n \), \( 2^n + 3^n \geq n^2 + 2n + 2 \).

Proof We proceed by induction. Since \( 2^0 + 3^0 = 0^2 + 2 \cdot 0 + 2 \), the statement is true for \( n = 0 \). Assume, for an arbitrary nonnegative integer \( k \), that \( 2^k + 3^k \geq k^2 + 2k + 2 \). We show that

\[
2^{k+1} + 3^{k+1} \geq (k + 1)^2 + 2(k + 1) + 2 = k^2 + 4k + 5.
\]

Observe that

\[
2^{k+1} + 3^{k+1} = 2 \cdot 2^k + 3 \cdot 3^k \geq 2 \cdot 2^k + 2 \cdot 3^k = 2(2^k + 3^k) \geq 2(k^2 + 2k + 2) = 2k^2 + 4k + 4 = (k^2 + 4k + 5) + (k^2 - 1) \geq k^2 + 4k + 5.
\]

By the Principle of Mathematical Induction, \( 2^n + 3^n \geq n^2 + 2n + 2 \) for every nonnegative integer \( n \).

Proof Evaluation The proposed proof contains an error. The inequality

\[
(k^2 + 4k + 5) + (k^2 - 1) \geq k^2 + 4k + 5
\]

in the inductive step requires that \( k \geq 1 \). However, it is only known that \( k \geq 0 \). Hence, the case when \( k = 0 \) needs to be handled separately, that is, \( 2^{k+1} + 3^{k+1} = 2 + 3 = 5 = 0^2 + 4 \cdot 0 + 5 \). Once this has been observed, we can assume that \( k \geq 1 \) and proceed as above.

Example 7.15 Evaluate the proposed proof of the following statement.

Let \( a, b, c \in \mathbb{R} \). If at least one of \( a + b \), \( a + c \) and \( b + c \) is irrational, then at least one of \( a \), \( b \) and \( c \) is irrational.
The proposed proof attempts to prove the given statement using a proof by contradiction. Assume, to the contrary, that none of $a + b$, $a + c$ and $b + c$ are irrational. Then $p = a + b$, $q = a + c$ and $r = b + c$ are all rational. Therefore, $p + q + r = 2a + 2b + 2c$ is rational. Since $2r = 2b + 2c$ is rational, $(p + q + r) - 2r = 2a$ is rational, as is $2a/2 = a$. Similarly, $b$ and $c$ are rational and so all of $a$, $b$ and $c$ are rational. This is a contradiction. ■

Proof Evaluation  The proposed proof attempts to prove the given statement using a proof by contradiction. However, there are logical errors here. In a proof by contradiction, it should be assumed, to the contrary, that at least one of $a + b$, $a + c$ and $b + c$ is irrational but none of $a$, $b$ and $c$ are irrational. This would then imply that all of $a$, $b$ and $c$ are rational, from which it can be shown that all of $a + b$, $a + c$ and $b + c$ are rational. This would be a contradiction. ♦

EXERCISES FOR CHAPTER 7

7.1. We saw in Result 4.8 for integers $a$ and $b$ that $3 \mid ab$ if and only if $3 \mid a$ or $3 \mid b$. Use this fact to prove that if $m$ is an integer such that $10 \mid m$ and $12 \mid m$, then $60 \mid m$.

7.2. Let $a$, $b$, $m \in \mathbb{Z}$ with $m \geq 2$ such that $a \equiv b \pmod{m}$.

(a) According to Result 4.11, if $c$, $d \in \mathbb{Z}$ such that $c \equiv d \pmod{m}$, then $ac \equiv bd \pmod{m}$. Show that $a^2 \equiv b^2 \pmod{m}$ and $a^3 \equiv b^3 \pmod{m}$.

(b) Is it true that $a^2 \equiv b \pmod{m}$?

(c) Prove that $a^n \equiv b^n \pmod{m}$ for every positive integer $n$.

(d) Use (c) to prove that $8 \mid (3^n - 1)$ for every positive integer $n$.

(e) According to Result 4.6(b), if $x$ is an odd integer, then $8 \mid (x^2 - 1)$. Use this fact to prove that $8 \mid (3^n - 1)$ for every positive integer $n$.

7.3. (a) Let $m \in \mathbb{Z}$. Prove that if $m$ is the product of four consecutive integers, then $m + 1$ is a perfect square (that is, $m + 1 = k^2$ for some $k \in \mathbb{Z}$).

(b) Prove, for every positive integer $n$, that neither $n(n + 1)$ nor $n(n + 2)$ is a perfect square.

(c) Prove that the product of three consecutive integers is always divisible by 6 but not always divisible by 9. When will it be divisible by 12?

7.4. Let $a$, $b \in \mathbb{N}$. Prove that if $a + b$ is even, then there exist nonnegative integers $x$ and $y$ such that $x^2 - y^2 = ab$.

7.5. It follows from Result 4.6(b) that if $a$ is an odd integer, then $a^2 \equiv 1 \pmod{8}$. Use this fact to prove that if $b$ is an odd integer, then $b^2 \equiv 1 \pmod{2^{n+2}}$ for every positive integer $n$.

7.6. We saw in Exercise 4.90 that

\[ a \geq b \text{ and } c \geq d \implies ac \geq bd. \]  

(7.9)

(a) Use (7.9) to prove that if $a, b \in \mathbb{R}_+$ such that $a \geq b$, then $\sqrt{a} \geq \sqrt{b}$.

(b) Without using (7.9), prove that if $a, b \in \mathbb{R}_+$ such that $a \geq b$, then $\sqrt{a} \geq \sqrt{b}$.

7.7. (a) Let $m = 2k$ be an even integer where $k \in \mathbb{Z}$. Prove that if $a$ and $b$ are integers such that $a + b \geq m$, then either $a \geq k$ or $b \geq k + 1$.

(b) Let $m = 3k$ for some $k \in \mathbb{N}$. Prove that if $a, b, c \in \mathbb{N}$ such that $a + b + c \geq m$, then $a \geq k$, $b \geq k$ or $c \geq k + 2$.

(c) A set $S$ consists of 20 positive integers whose sum is an even integer. Prove that at least 4 elements of $S$ are congruent to 0 modulo 4, at least 5 are congruent to 1 modulo 4, at least 7 are congruent to 2 modulo 4 or at least 8 are congruent to 3 modulo 4.
Chapter 7  Reviewing Proof Techniques

7.8. (a) Express the following statement in words: \( \forall n \in \{3, 4, 5, \ldots\}, \exists a_1, a_2, \ldots, a_n \in \mathbb{N} \) with \( a_1 < a_2 < \cdots < a_n \) such that \( \frac{1}{a_1} + \frac{1}{a_2} + \cdots + \frac{1}{a_n} = 1 \).
(b) Express in words the negation of the statement in (a).
(c) One of the statements in (a) and (b) is true. Determine, with proof, which is true.

7.9. Prove for every positive integer \( m \) that is a multiple of 8, there exist two positive integers \( a \) and \( b \) that differ by \( m \) such that \( ab \) is a perfect square.

7.10. A sequence \( \{a_n\} \) is defined recursively by \( a_1 = 7 \) and \( a_n = 4a_{n-1} - 9 \) for \( n \geq 2 \). Conjecture a formula for \( a_n \) and verify your conjecture for every positive integer \( n \).

7.11. The triples (3, 4, 5), (5, 12, 13) and (7, 24, 25) are called Pythagorean triples because \( 3^2 + 4^2 = 5^2 \), \( 5^2 + 12^2 = 13^2 \) and \( 7^2 + 24^2 = 25^2 \). There are infinitely many Pythagorean triples.
(a) Prove for every odd integer \( a \geq 3 \) that there exists an even integer \( b \) such that \( (a, b, b+1) \) is a Pythagorean triple.
(b) Prove for every integer \( a \geq 3 \) and positive integer \( n \), that there exist \( n \) positive even integers \( b_1, b_2, \ldots, b_n \) such that \( a^2 + b_1^2 + b_2^2 + \cdots + b_n^2 = c^2 \) for some positive integer \( c \).

7.12. Use induction to prove that \( 11^n \equiv 1 \pmod{8} \) or \( 11^n \equiv 3 \pmod{8} \) for every nonnegative integer \( n \).

7.13. Prove for every three integers \( a, b \) and \( c \) that an even number of the integers \( a+b, a+c \) and \( b+c \) are odd.

7.14. Evaluate the proof of the following statement.

**Statement**  If \( x \) is an integer such that \( 3 \mid (x - 5) \), then \( 3 \mid (7x - 2) \).

**Proof**  The integer \( x = 5 \) has the property that \( 3 \mid (x - 5) \). Furthermore, for \( x = 5, 3 \mid (7x - 2) \).

7.15. Evaluate the proof of the following statement.

**Statement**  Let \( x, y, z \in \mathbb{Z} \) such that \( 3x + 5y = 7z \). If at least one of \( x, y \) and \( z \) is odd, then at least one of \( x, y, z \) is even.

**Proof**  Let \( x, y, z \in \mathbb{Z} \) such that \( 3x + 5y = 7z \). Assume, to the contrary, that none of \( x, y \) and \( z \) is odd and that none of \( x, y, z \) is even. This is impossible.

7.16. Evaluate the proof of the following statement.

**Statement**  A sequence \( \{a_n\} \) of integers is defined recursively by \( a_1 = 1, a_2 = 3, a_3 = 6 \) and \( a_n = a_{n-1} + 3a_{n-2} + 6a_{n-3} \) for \( n \geq 4 \). Then \( 3 \mid a_n \) for every integer \( n \geq 2 \).

**Proof**  We proceed by induction. Since \( a_2 = 3 \), it follows that \( 3 \mid a_k \) for \( k = 2 \). Assume that \( 3 \mid a_k \) for an integer \( k \geq 2 \). Thus, \( a_k = 3x \) for some integer \( x \). We show that \( 3 \mid a_{k+1} \). Now
\[
a_{k+1} = a_k + 3a_{k-1} + 6a_{k-2} = 3x + 3a_{k-1} + 6a_{k-2} = 3(x + a_{k-1} + 2a_{k-2}).
\]
Since \( x + a_{k-1} + 2a_{k-2} \) is an integer, \( 3 \mid a_{k+1} \). By the Principle of Mathematical Induction, \( 3 \mid a_n \) for every integer \( n \geq 2 \).

7.17. Evaluate the proof of the following statement.

**Statement**  Let \( a \in \mathbb{R}^+ \) and let \( S = \{2^r : r \in \mathbb{Q}\} \). If \( a \notin S \), then \( \log_2 a \) is irrational.

**Proof**  Assume, to the contrary, that \( \log_2 a \) is rational. Then \( \log_2 a = b \in \mathbb{Q} \) and so \( a = 2^b \). Since \( b \in \mathbb{Q} \), it follows that \( a \in S \), which is a contradiction.

7.18. Evaluate the proof of the following statement.

**Statement**  Let \( a, b, c \in \mathbb{Z} \). If all of the integers \( 3a + 4b, 5b + 6c \) and \( 7c + 8a \) are odd, then all of \( a, b, c \) are odd.
Exercises for Chapter 7

195

Proof Assume, to the contrary, that not all of the integers 3a + 4b, 5b + 6c and 7c + 8a are odd, say 3a + 4b is not odd. Then 3a + 4b is even and so 3a + 4b = 2d for some integer d. Hence, 3a = 2d − 4b = 2(d − 2b). Since d − 2b ∈ \(\mathbb{Z}\), it follows that 3a is even. This, however, implies that a is even and so not all of a, b, c are odd.

7.19. Evaluate the proof of the following statement.

Statement Let a, b, c ∈ \(\mathbb{Z}\). Then \(ab + ac + bc\) is even if and only if at most one of a, b and c is odd.

Proof We consider the following cases.

Case 1. None of a, b and c is odd. Then all of a, b and c are even. Hence, \(ab, ac\) and \(bc\) are even, as is \(ab + ac + bc\).

Case 2. Exactly one of a, b and c is odd, say a is odd. Then b and c are even. Hence, all of \(ab, ac\) and \(bc\) are even, as is \(ab + ac + bc\).

Case 3. Exactly two of a, b and c are odd, say a and b are odd and c is even. Then \(ab\) is odd and \(ac\) and \(bc\) are even. Hence, \(ab + ac + bc\) is odd.

Case 4. All of a, b and c are odd. Hence, \(ab, ac\) and \(bc\) are odd, as is \(ab + ac + bc\).
Therefore, \(ab + ac + bc\) is even if and only if at most one of a, b and c is odd.

7.20. In Result 6.5, it was shown that

\[1^2 + 2^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}\]

for every positive integer n.

Evaluate the proof of the following statement.

Statement For every integer \(n \geq 3\),

\[1^2 + 2^2 + \cdots + (n - 1)^2 < \frac{n^3}{3} - n\]

Proof Assume, to the contrary, that

\[1^2 + 2^2 + \cdots + (n - 1)^2 \geq \frac{n^3}{3} - n\]

for every integer \(n \geq 3\). By Result 6.5, it follows that

\[1^2 + 2^2 + \cdots + n^2 = \frac{n(n + 1)(2n + 1)}{6}\]

Therefore,

\[\frac{(n - 1)n(2n - 1)}{6} \geq \frac{n^3}{3} - n\]

and so

\[\frac{2n^3 - 3n^2 + n}{6} \geq \frac{n^3 - 3n}{3}\]

Hence, \(2n^3 - 3n^2 + n \geq 2n^3 - 6n\) and so \(3n^2 - 7n = n(3n - 7) \leq 0\). Since n is a positive integer, \(n \leq 7/3\), which is a contradiction.

7.21. Let A and B be nonempty sets. Prove that \(A \times B = B \times A\) if and only if \(\mathcal{P}(A) = \mathcal{P}(B)\).

7.22. The Fibonacci sequence \(F_1, F_2, F_3, \ldots\) of integers is defined recursively by \(F_1 = F_2 = 1\) and \(F_n = F_{n-1} + F_{n-2}\) for each integer \(n \geq 3\). (This sequence also occurred in Exercise 6.36.) Prove that if
200  Chapter 7  Reviewing Proof Techniques

\[ a_0, a_1, a_2, \ldots \] is a sequence of rational numbers such that \( a_0 = \frac{1}{2}, a_1 = \frac{3}{2} \) and \( a_n = \frac{a_{n-1}}{2} \) for every integer \( n \geq 2 \), then for every positive integer \( n \),

\[
a_n = \begin{cases} 
\frac{y_n}{2^{n+1}} & \text{if } n \text{ is even} \\
\frac{y_{n+1}}{2^{n}} & \text{if } n \text{ is odd.}
\end{cases}
\]

7.23. Prove that if the real number \( r \) is a root of a polynomial with integer coefficients, then \( 2r \) is a root of a polynomial with integer coefficients.

7.24. Prove that if the real number \( r \) is a root of a polynomial with integer coefficients, then \( r/2 \) is a root of a polynomial with integer coefficients.

7.25. Prove, for every nonnegative integer \( n \), that

\[ 2^{2n} + 2^n \equiv 2^{2n+1} \pmod{21}. \]

7.26. Let \( n \in \mathbb{Z} \). Prove that \( n+1 \) and \( n^2 + 3 \) are of the same parity.

7.27. Prove that an integer \( m \) equals \( n(n+1)/2 \) for some \( n \in \mathbb{N} \) if and only if \( 8m + 1 \) is a perfect square (that is, \( 8m + 1 = t^2 \) for some \( t \in \mathbb{N} \)).

7.28. By Result 4.8, if \( a, b \in \mathbb{N} \) and \( 3 \mid ab \), then \( 3 \mid a \) or \( 3 \mid b \). Let \( a \) and \( n \) be positive integers. Prove each of the following statements.

(a) If \( 3 \mid a^n \), then \( 3 \mid a \).

(b) If \( 3 \nmid a^n \), then \( 3^n \mid a^n \).

7.29. Prove that there do not exist two odd integers \( a \) and \( b \) with \( a \neq b \pmod{4} \) such that \( 4 \mid (3a + 5b) \).

7.30. Prove that there exist three distinct integers \( a, b, c \geq 2 \) such that \( a \equiv b \pmod{c} \), \( b \equiv c \pmod{a} \) and \( a + c \equiv 0 \pmod{b} \).

7.31. (a) Prove that there exists a 10-digit integer \( a = a_10a_9 \cdots a_1 \), all of whose digits are distinct, with the property that \( k \) divides \( a_k a_{k-1} \cdots a_1 \) for each \( k \) with \( 1 \leq k \leq 10 \).

(b) Prove that there exists a 10-digit integer \( b = b_1b_2 \cdots b_{10} \), all of whose digits are distinct, with the property that \( k \) divides \( b_1b_2 \cdots b_k \) for each \( k \) with \( 1 \leq k \leq 10 \).

(c) The number \( n = 2468 \) is a 4-digit integer with distinct digits such that the first and last digits are divisible by 1 (of course), the first and last 2-digit numbers of \( n \), namely 24 and 68, are divisible by 2, the first and last 3-digit numbers of \( n \) are divisible by 3, and \( n \) itself is divisible by 4. Is there a 5-digit number \( m \) with the corresponding properties?

7.32. Let \( S = \{1, 2, 3, 4, 5, 6 \} \). Prove that there exists a collection \( T \) of five subsets of \( S \) such that for every two sets \( A \) and \( B \) in \( T \), there is a unique set \( C \) in \( T \) for which \( |A \cap C| = |B \cap C| = 1 \).

7.33. According to Result 3.16, for two integers \( a \) and \( b \), \( a + b \equiv 0 \pmod{2} \) if and only if \( a \equiv b \pmod{2} \). Let \( a, b, c \in \mathbb{Z} \). Prove that \( a + b + c \equiv 0 \pmod{3} \) if and only if either every two integers in \( \{a, b, c\} \) are congruent modulo 3 or no two integers in \( \{a, b, c\} \) are congruent modulo 3.

7.34. We have seen that a triple \( (a, b, c) \) of positive integers is a Pythagorean triple if \( a^2 + b^2 = c^2 \). Therefore, if \( (a, b, c) \) is a Pythagorean triple, then \( \left( \frac{a}{c} \right)^2 + \left( \frac{b}{c} \right)^2 = 1 \).

(a) Show that if \( u \) and \( v \) are real numbers such that \( u^2 + v^2 = 1 \), then \( (u + v)^2 + (u - v)^2 = 2 \).

(b) We saw in Result 5.30 that there are no rational solutions to the equation \( x^2 + y^2 = 3 \). Prove that there are infinitely many rational solutions to the equation \( x^2 + y^2 = 2 \).

(c) How many rational solutions to the equation \( x^2 + y^2 = 4 \) are there?

7.35. Prove, for every integer \( n \geq 4 \), that \( n! > n^2 \).

7.36. An office contains two tables, called Table 1 and Table 2. There are \( n \) cards on Table 1. On the bottom of each card is written a positive rational number. A total of \( k \) cards are randomly selected from Table 1 and
placed on Table 2. Each of these $k$ cards is turned over and the number on it is multiplied by $\sqrt{2}$ and turned over again. The $k$ cards on Table 2 are then returned to Table 1 and all $n$ cards on Table 1 are shuffled. Then once again, $k$ cards from Table 1 are randomly selected from Table 1 and placed on Table 2. Each of these $k$ cards is turned over and the number on it is multiplied by $\sqrt{2}$. This time, however, these $k$ cards are left on Table 2. Suppose now that $a_1$ of the cards on Table 1 contain an irrational number and $a_2$ of the cards on Table 2 contain an irrational number. Which of the following can be said about $a_1$ and $a_2$?

1. $a_1 < a_2$
2. $a_1 = a_2$
3. $a_1 > a_2$
4. It is impossible to determine any relationship between $a_1$ and $a_2$.

7.37. Below is given a proof of a result. Which result is being proved and which proof technique is being used?

**Proof** Assume that $3x + 5y$ is odd. Then $3x + 5y = 2z + 1$, where $z \in \mathbb{Z}$. Then

$$7x - 11y = (3x + 5y) + (4x - 16y) = (2z + 1) + (4x - 16y)$$

$$= 2(z + 2x - 8y) + 1.$$

Since $z + 2x - 8y$ is an integer, $7x - 11y$ is odd.

For the converse, assume that $7x - 11y$ is odd. Then $7x - 11y = 2w + 1$ for some integer $w$. Then

$$3x + 5y = (7x - 11y) + (-4x + 16y) = (2w + 1) + (-4x + 16y)$$

$$= 2(w - 2x + 8y) + 1.$$

Since $w - 2x + 8y$ is an integer, $3x + 5y$ is odd.

7.38. Below is given a proof of a result. Which result is being proved and which proof technique is being used?

**Proof** Assume, to the contrary, that there are integers $a$ and $b$ such that $a^2 - 4b^2 = 2$. Certainly, $a$ is not odd, for otherwise, $a^2$ and $a^2 - 4b^2$ are odd and so $a^2 - 4b^2 \neq 2$. Thus, $a$ must be even and so $a = 2c$ for some integer $c$. Therefore,

$$a^2 - 4b^2 = (2c)^2 - 4b^2 = 4c^2 - 4b^2 = 4(c^2 - b^2) = 2.$$

Since $c^2 - b^2$ is an integer, $4 | 2$, which is impossible.

7.39. Prove that there exist three distinct real number solutions to the polynomial equation $x^3 - 3x + 1 = 0$.

7.40. Prove that there exists no integer $a$ for which $a \equiv 17 \pmod{35}$ and $2a \equiv 43 \pmod{49}$.

7.41. We have seen that $\sum_{i=1}^{n} i = \frac{n(n+1)}{2}$ for every positive integer $n$. The statement below suggests that there is another expression for this sum. Evaluate the proof of the following statement.

**Statement** For every positive integer $n$, $\sum_{i=1}^{n} i = \frac{(2n+1)^2}{8}$.

**Proof** We proceed by induction. First, observe that the statement is true for $n = 1$. Assume that the statement is true for a positive integer $k$. Thus, $\sum_{i=1}^{k} i = \frac{(2k+1)^2}{8}$. We show that $\sum_{i=1}^{k+1} i = \frac{(2k+3)^2}{8}$. Now,

$$\sum_{i=1}^{k+1} i = \left(\sum_{i=1}^{k} i\right) + (k + 1) = \frac{(2k+1)^2}{8} + (k + 1)$$

$$= \frac{4k^2 + 4k + 1 + 8(k + 1)}{8} = \frac{4k^2 + 12k + 9}{8} = \frac{(2k+3)^2}{8}.$$

Thus, $\sum_{i=1}^{n} i = \frac{(2n+1)^2}{8}$ for every positive integer $n$ by the Principle of Mathematical Induction.
Chapter 7  Reviewing Proof Techniques

7.42. Evaluate the proof of the following statement.

**Statement**  For each positive integer \( n \), every set of \( n \) real numbers consists only of equal numbers.

**Proof**  We proceed by induction. Certainly, if a set consists of a single real number, then all numbers in the set are equal. Assume, for a positive integer \( k \), that the numbers in every set of \( k \) real numbers are equal. Let \( S \) be a set of \( k+1 \) real numbers, say \( S = \{a_1, a_2, \ldots, a_{k+1}\} \). Let \( S_1 = \{a_1, a_2, \ldots, a_k\} \) and \( S_2 = \{a_2, a_3, \ldots, a_{k+1}\} \) be two subsets of \( S \), each consisting of \( k \) real numbers. By the induction hypothesis, all numbers in \( S_1 \) are equal and numbers in \( S_2 \) are equal, that is, \( a_1 = a_2 = \cdots = a_k \) and \( a_2 = a_3 = \cdots = a_{k+1} \). Therefore, \( a_1 = a_2 = \cdots = a_k = a_{k+1} \) and so all numbers in \( S \) are equal. By the Principle of Mathematical Induction, every set of \( n \) real numbers consists only of equal numbers for every positive integer \( n \).

7.43. Evaluate the proof of the following statement.

**Statement**  For every nonnegative integer \( n \), \( e^n = 1 \).

**Proof**  We proceed by the Strong Principle of Mathematical Induction. First, since \( e^0 = 1 \), the statement is true for \( n = 0 \). Assume, for a nonnegative integer \( k \), that \( e^i = 1 \) for every integer \( i \) with \( 0 \leq i \leq k \). We show that \( e^{k+1} = 1 \). Observe that

\[
e^{k+1} = e^k \cdot e^1 = \frac{1 \cdot 1}{1} = 1.
\]

By the Strong Principle of Mathematical Induction, \( e^n = 1 \) for every nonnegative integer \( n \).

7.44. Prove that if \( a \) is a real number such that \( |a| < r \) for every positive real number \( r \), then \( a = 0 \).

7.45. Below is given a proof of a result. Which result is being proved and which proof technique is being used?

**Proof**  First, observe that \( 3^0 + 1 = 2 \geq 1^2 = 1 \), which verifies the basis step. Assume that \( 3^k + 1 \geq (k+1)^2 \) for some nonnegative integer \( k \). We show that \( 3^{k+1} + 1 \geq (k+2)^2 \). When \( k = 0 \), we have \( 3^1 + 1 = 4 = 2^2 \). Hence, we may assume that \( k \) is a positive integer. Observe that

\[
3^{k+1} + 1 = 3 \cdot 3^k + 1 \geq 3[(k+1)^2 - 1] + 1 \\
= 3(k^2 + 2k) + 1 = 3k^2 + 6k + 1 = (k^2 + 4k) + (2k^2 + 2k) + 1 \\
\geq k^2 + 4k + 2 + 2 + 1 \geq k^2 + 4k + 4 = (k + 2)^2.
\]

7.46. Evaluate the proof of the following statement.

**Statement**  If \( a_1, a_2, \ldots, a_n \) are \( n \) real numbers such that \( a_1a_2 \cdots a_n = 0 \), then \( a_i = 0 \) for some \( i \) with \( 1 \leq i \leq n \).

**Proof**  We proceed by induction. Certainly, the statement is true for \( n = 1 \). Assume that the statement is true for some positive integer \( k \). Now, let \( b_1, b_2, \ldots, b_{k+1} \) be \( k+1 \) real numbers such that \( b_1b_2 \cdots b_{k+1} = 0 \). Thus, \((b_1b_2 \cdots b_k)b_{k+1} = 0\) and hence either \( b_1b_2 \cdots b_k = 0 \) or \( b_{k+1} = 0 \). If \( b_1b_2 \cdots b_k = 0 \), then it follows by the induction hypothesis that \( b_1 = 0 \) for some integer \( i \) with \( 1 \leq i \leq k \). If this is not the case, then \( b_{k+1} = 0 \). Hence, \( b_i = 0 \) for some integer \( i \) with \( 1 \leq i \leq k+1 \). Therefore, the statement is true by the Principle of Mathematical Induction.

7.47. Evaluate the proof of the following statement.

**Statement**  If \( n \geq 10 \) is an integer, then \( n^3 \geq 100 + 9n^2 \).

**Proof**  First, observe that if \( n = 10 \), then \( n^3 = 1000 \) and \( 100 + 9n^2 = 100 + 900 = 1000 \) and so \( n^3 = 100 + 9n^2 \). More generally, observe that \( n^3 \geq 100 + 9n^2 \) can be written as \( n^3 - 9n^2 \geq 100 \) and so \( n^2(n - 9) \geq 100 \). Since \( n \geq 10 \), we have \( n^2 \geq 100 \) and \( n - 9 \geq 1 \). Therefore, \( n^2(n - 9) \geq 100 \cdot 1 = 100 \).
Exercises for Chapter 7

7.48. It is clear that $3 + 4 > 5$ and $3^2 + 4^2 = 5^2$. Prove that $3^n + 4^n < 5^n$ for every integer $n \geq 3$.

7.49. Prove that if $a_1, a_2, a_3, \ldots$ is a sequence of numbers such that $a_1 = 1$ and $a_n = \frac{n-1}{n} a_{n-1}$ for each integer $n \geq 2$, then $a_n = \frac{1}{n}$ for every positive integer $n$.

7.50. For positive real numbers $a, b, c$ and $d$, it follows that

$$\sqrt{a^2 + b^2 + c^2 + d^2} \neq a + b + c + d.$$ 

For example, if $a = 1, b = c = 2$ and $d = 4$, then $a + b + c + d = 9$ while $\sqrt{a^2 + b^2 + c^2 + d^2} = 5$. In fact, in this case,

$$\sqrt{a^2 + b^2 + c^2 + d^2} < a + b + c + d < 2\sqrt{a^2 + b^2 + c^2 + d^2}.$$ 

(a) Prove for every four positive real numbers $a, b, c$ and $d$ that

$$\sqrt{a^2 + b^2 + c^2 + d^2} < a + b + c + d.$$ 

(b) Prove for every four positive real numbers $a, b, c$ and $d$ that

$$a + b + c + d \leq 2\sqrt{a^2 + b^2 + c^2 + d^2}.$$  \hspace{1cm} (7.10)

Furthermore, show that equality holds in (7.10) if and only if $a = b = c = d$.

The Chapter Presentation for Chapter 7 can be found at goo.gl/7ysHA3
Prove or Disprove

In every mathematical statement that you have seen so far, you have been informed of its truth value. If the statement was true, then we have either provided a proof or have asked you to provide one of your own. What you didn’t know (perhaps) was how we or you were to verify its truth. If the statement was false, then here too we either verified this or asked you to verify that it was false. As you proceed further into the world of mathematics, you will more and more often encounter statements whose truth is in question. Consequently, each such statement presents two problems for you: (1) Determine the truth or falseness of the statement. (2) Verify the correctness of your belief.

8.1 CONJECTURES IN MATHEMATICS

In mathematics, when we don’t know whether a certain statement is true but there is good reason to believe that it is, then we refer to the statement as a conjecture. So, the word “conjecture” is used in mathematics as a sophisticated synonym for an intelligent guess (or perhaps just a guess). Once a conjecture is proved, then the conjecture becomes a theorem. If, on the other hand, the conjecture is shown to be false, then we made an incorrect guess. This is the way mathematics develops – by guessing and showing that our guess is correct or wrong and then possibly making a new conjecture and then repeating the process (possibly often). As we learn what’s true and what’s false about the mathematics we’re studying, this influences the questions we ask and the conjectures we make.

Let’s consider an example of a conjecture (although there is always the possibility that someone has settled the conjecture between the time it was written here and the moment you read it). A word is called a palindrome if it reads the same forward and backward (such as deed, noon and radar). Indeed, a sentence is a palindrome if it reads the same forward and backward, ignoring spaces (Name no one man). A positive integer is called a palindrome if it is the same number when its digits are reversed. (It is considerably easier to give an example of a number that is a palindrome than a word that is a palindrome.) For example, 1221 and 47374 are palindromes. Consider the integer 27. It is not a palindrome. Reverse its digits and we obtain 72. Needless to say, 72 is not a palindrome either. Adding 27 and 72, we have:
8.1 Conjectures in Mathematics

27
+ 72
\[ \begin{array}{c} 99 \end{array} \]

A palindrome results. Consider another positive integer, say 59. It is not a palindrome. Reverse its digits and add:

\[ \begin{array}{c} 59 \\ + 95 \\ \hline 154 \end{array} \]

The result is not a palindrome either. Reverse its digits and add:

\[ \begin{array}{c} 154 \\ + 451 \\ \hline 605 \end{array} \]

Once again we arrive at a number that is not a palindrome. But reverse its digits and add:

\[ \begin{array}{c} 605 \\ + 506 \\ \hline 1111 \end{array} \]

This time the result is a palindrome. It has been conjectured that if we begin with any positive integer and apply the technique described above to it, then we will eventually arrive at a palindrome. However, no one knows if this is true. (It is known to be true for all two-digit numbers.)

Some conjectures have become famous because it has taken years, decades or even centuries to establish their truth or falseness. Other conjectures remain undecided still today. We now consider four conjectures in mathematics, each of which has a long history.

In 1852, a question occurred to the British student Francis Guthrie when he was coloring a map of the counties of England. Suppose that some country (real or imaginary) has been divided into counties in some manner. Is it possible to color the counties in this map with four or fewer colors such that one color is used for each county and two counties that share a common boundary (not simply a single point) are colored differently? For example, the map of the “country” shown in Figure 8.1 has eight “counties,” which are colored with the four colors red (R), blue (B), green (G) and yellow (Y), according to the rules described above. This map can also be colored with more than four colors but not less than four.

![Figure 8.1](image_url)  

**Figure 8.1** Coloring the counties in a country with four colors
Within a few years, some of the best known mathematicians of the time had become aware of Francis Guthrie’s question and eventually a famous conjecture developed from this.

**The Four Color Conjecture**

Every map can be colored with four or fewer colors.

Many attempted to settle this conjecture. In fact, in 1879 an article was published containing a reported proof of the conjecture. However, in 1890, an error was discovered in the proof and the “theorem” returned to its conjecture status. It was not until 1976 when an actual proof by Kenneth Appel and Wolfgang Haken, combining both mathematics and computers, was presented. The period between the origin of the problem and its solution covered some 124 years. This is now a theorem.

**The Four Color Theorem**

Every map can be colored with four or fewer colors.

We now describe a conjecture with an even longer history. One of the famous mathematicians of the 17th century was Pierre Fermat. He is undoubtedly best known for one particular assertion he made. He wrote that for each integer \( n \geq 3 \), there are no nonzero integers \( x, y \) and \( z \) such that \( x^n + y^n = z^n \). Of course, there are many nonzero integer solutions to the equation \( x^2 + y^2 = z^2 \). For example, \( 3^2 + 4^2 = 5^2 \), \( 5^2 + 12^2 = 13^2 \) and \( 8^2 + 15^2 = 17^2 \). A triple \((x, y, z)\) of positive integers such that \( x^2 + y^2 = z^2 \) is often called a *Pythagorean triple*. Therefore, \((3, 4, 5), (5, 12, 13)\) and \((8, 15, 17)\) are Pythagorean triples. Indeed, if \((a, b, c)\) is a Pythagorean triple and \( k \in \mathbb{Z} \), then \((ka, kb, kc)\) is also a Pythagorean triple. Fermat’s assertion was discovered, unproved, in a margin of a book of Fermat’s after his death. In the margin it was written that there was insufficient space to contain his “truly remarkable demonstration.” Consequently, this statement became known as Fermat’s Last Theorem. It would have been more appropriate, however, to have referred to this statement as Fermat’s Last Conjecture as the truth or falseness of this statement remained in question for approximately 350 years. However, in 1993, the British mathematician Andrew Wiles settled the conjecture by giving a truly remarkable proof of it. Hence, Fermat’s Last Theorem is at last a theorem.

**Fermat’s Last Theorem**

For each integer \( n \geq 3 \), there are no nonzero integers \( x, y \) and \( z \) such that \( x^n + y^n = z^n \).

The final two conjectures we mention concern primes. Although we have mentioned primes from time to time, we have not yet presented a formal definition. We do this now. An integer \( p \geq 2 \) is a **prime** if its only positive integer divisors are 1 and \( p \). A **Fermat number** (Yes, the same Fermat!) is an integer of the form \( F_t = 2^{2^t} + 1 \), where \( t \) is a nonnegative integer. The first five Fermat numbers are 

\[
F_0 = 3, \quad F_1 = 5, \quad F_2 = 17, \quad F_3 = 257, \quad F_4 = 65,537,
\]

all of which happen to be primes.

In 1640 Fermat wrote to many (including to the famous mathematician Blaise Pascal) that he believed every such number (he didn’t call them Fermat numbers) was a prime but he was unable to prove this. Hence, we have the following.
Section 8.1 Exercises

Fermat’s Conjecture

Every Fermat number is a prime.

Nearly one century later (in 1739), the famous mathematician Leonhard Euler proved that $F_5 = 4,294,967,297$ is divisible by 641, thereby disproving Fermat’s Conjecture. More specifically, Euler proved the following.

Euler’s Theorem

If $p$ is a prime factor of $F_t$, then $p = 2^{t+1}k + 1$ for some positive integer $k$.

Letting $t = 5$ in Euler’s Theorem, we see that each prime factor of $F_5$ is of the form $64k + 1$. The first five primes of this form are 193, 257, 449, 577 and 641, the last of which divides $F_5$.

In recent decades, other Fermat numbers have been studied and have been shown not to be prime. Indeed, many students of this topic now lean toward the opposing viewpoint (and conjecture): Except for the Fermat numbers $F_0$, $F_1$, ···, $F_4$ (all of which were observed to be prime by Fermat), no Fermat number is prime.

The last conjecture we describe here has its origins around 1742. The German mathematician Christian Goldbach conjectured that every even integer exceeding 2 is the sum of two primes. Of course, this is easy to see for small even integers. For example, $4 = 2 + 2$, $6 = 3 + 3$, $8 = 5 + 3$ and $10 = 7 + 3 = 5 + 5$. The major difference between this conjecture and the three preceding conjectures is that this conjecture has never been resolved. Hence, we conclude with the following.

Goldbach’s Conjecture

Every even integer at least 4 is the sum of two primes.

SECTION 8.1 EXERCISES

8.1. Consider the following sequence of equalities:

1 = 0 + 1
2 + 3 + 4 = 1 + 8
5 + 6 + 7 + 8 + 9 = 8 + 27
10 + 11 + 12 + 13 + 14 + 15 + 16 = 27 + 64

(a) What is the next equality in this sequence?
(b) What conjecture is suggested by these equalities?
(c) Prove the conjecture in (b) by induction.

8.2. Consider the following statements:

$(1 + 2)^2 - 1^2 = 2^3$
$(1 + 2 + 3)^2 - (1 + 2)^2 = 3^3$
$(1 + 2 + 3 + 4)^2 - (1 + 2 + 3)^2 = 4^3$

(a) Based on the three statements given above, what is the next statement suggested by these?
(b) What conjecture is suggested by these statements?
(c) Verify the conjecture in (b).
Chapter 8: Prove or Disprove

8.3. A sequence \( \{a_n\} \) of real numbers is defined recursively by \( a_1 = 2 \) and for \( n \geq 2 \),
\[
a_n = \frac{2 + 1 \cdot a_1^2 + 2 \cdot a_2^2 + \cdots + (n-1) a_{n-1}^2}{n}.
\]
(a) Determine \( a_2 \), \( a_3 \) and \( a_4 \).
(b) Clearly, \( a_n \) is a rational number for each \( n \in \mathbb{N} \). Based on the information in (a), however, what conjecture does this suggest?

8.4. It has been stated that the German mathematician Christian Goldbach is known for a conjecture he made concerning primes. We refer to this conjecture as Conjecture A.

**Conjecture A** Every even integer at least 4 is the sum of two primes.

Goldbach made two other conjectures concerning primes.

**Conjecture B** Every integer at least 6 is the sum of three primes.

**Conjecture C** Every odd integer at least 9 is the sum of three odd primes.

Prove that the truth of one or more of these three conjectures implies the truth of one or two of the other conjectures.

8.5. By an ordered partition of an integer \( n \geq 2 \) is meant a sequence of positive integers whose sum is \( n \). For example, the ordered partitions of 3 are 3, 1+2, 2+1, 1+1+1.

(a) Determine the ordered partitions of 4.
(b) Make a conjecture concerning the number of ordered partitions of an integer \( n \geq 2 \).

8.6. Two recursively-defined sequences \( \{a_n\} \) and \( \{b_n\} \) of positive integers have the same recurrence relation, namely \( a_n = 2a_{n-1} + a_{n-2} \) and \( b_n = 2b_{n-1} + b_{n-2} \) for \( n \geq 3 \). The initial values for \( \{a_n\} \) are \( a_1 = 1 \) and \( a_2 = 3 \), while the initial values for \( \{b_n\} \) are \( b_1 = 1 \) and \( b_2 = 2 \).

(a) Determine \( a_3 \) and \( a_4 \).
(b) Determine \( b_3 \) and \( b_4 \).
(c) Determine whether the following is true or false:
**Conjecture:** \( a_n = 2^{n-2} \cdot n + 1 \) for every integer \( n \geq 2 \).
(d) Determine whether the following is true or false:
**Conjecture:** \( b_n = \frac{(1+\sqrt{2})^n-(1-\sqrt{2})^n}{2 \sqrt{2}} \) for every integer \( n \geq 2 \).

8.7. We know that \( 1 + 2 + 3 = 1 \cdot 2 \cdot 3 \), that is, there exist three positive integers whose sum equals their product. Prove or disprove (a) and (b).
(a) There exist four positive integers whose sum equals their product.
(b) There exist five positive integers whose sum equals their product.
(c) What conjecture does this suggest to you?

8.8. Observe that \( 3 = 1 + 2, 6 = 1 + 2 + 3, 9 = 4 + 5 \) and \( 12 = 3 + 4 + 5 \).

(a) Show that 13 and 14 can be expressed as the sum of two or more consecutive positive integers.
(b) Make a conjecture as for which integers \( n \geq 3 \) can be expressed as the sum of two or more consecutive positive integers.
(c) Prove your conjecture in (b). [Note that every positive integer \( n \) can be expressed as \( n = 2^r s \), where \( r \) is a nonnegative integer and \( s \) is a positive odd integer.]

8.9. A sequence \( a_2, a_3, a_4, \ldots \) of real numbers is defined recursively by \( a_2 = 1 + \frac{1}{2}, a_n = a_{n-1} + \frac{1}{n} \) for \( n \geq 3 \).

(a) Determine \( a_3 \) and \( a_4 \).
(b) Certainly, \( a_n \) is a rational number for \( n \geq 2 \). Based on the information in (a), what conjecture is suggested?
8.2 REVISITING QUANTIFIED STATEMENTS

As we review the conjectures described in the preceding section, we see that each concerns the truth or falseness of a quantified statement: for every positive integer, for every map, for every integer \( n \geq 3 \), every Fermat number, every even integer at least 4. Indeed, most of the statements we have encountered and will encounter in the future are quantified statements. Because of the obvious importance of quantified statements, it is of value to review these in greater detail. For an open sentence \( P(x) \) over a domain \( S \), we have often considered a quantified statement with a universal quantifier as the following:

\[
\forall x \in S, P(x): \text{For every } x \in S, P(x).
\]

while a quantified statement with an existential quantifier is:

\[
\exists x \in S, P(x): \text{There exists } x \in S \text{ such that } P(x).
\]

Recall that \( \forall x \in S, P(x) \) is a true statement if \( P(x) \) is true for every \( x \in S \); while \( \exists x \in S, P(x) \) is a true statement if \( P(x) \) is true for at least one \( x \in S \). Let's look at several examples of this.

**Example 8.1** Let \( S = \{1, 3, 5, 7\} \) and consider

\[
P(n): \quad n^2 + n + 1 \text{ is prime.}
\]

for each \( n \in S \). Then both

\[
\forall n \in S, P(n): \text{For every } n \in S, n^2 + n + 1 \text{ is prime.}
\]

and

\[
\exists n \in S, P(n): \text{There exists } n \in S \text{ such that } n^2 + n + 1 \text{ is prime.}
\]

are quantified statements. Since

\[
P(1): \quad 1^2 + 1 + 1 = 3 \text{ is prime. is true,}
P(3): \quad 3^2 + 3 + 1 = 13 \text{ is prime. is true,}
P(5): \quad 5^2 + 5 + 1 = 31 \text{ is prime. is true,}
P(7): \quad 7^2 + 7 + 1 = 57 \text{ is prime. is false,}
\]

it follows that \( \forall n \in S, P(n) \) is false and \( \exists n \in S, P(n) \) is true. On the other hand, the statement

\[
Q: \quad 323 \text{ is prime.}
\]

is not a quantified statement but \( Q \) is false (as \( 323 = 17 \cdot 19 \) is not prime).

Let \( P(x) \) be a statement for each element \( x \) belonging to some domain \( S \). Recall that the negation of \( \forall x \in S, P(x) \) is

\[
\sim (\forall x \in S, P(x)) \equiv \exists x \in S, \sim P(x).
\]
206  Chapter 8  Prove or Disprove

and the negation of \( \exists x \in S, P(x) \) is

\[
\sim (\exists x \in S, P(x)) \equiv \forall x \in S, \sim P(x).
\]

Again, consider

\( P(n): n^2 + n + 1 \) is prime.

from Example 8.1, which is a statement for each \( n \) in \( S = \{1, 3, 5, 7\} \). The negation of \( \forall n \in S, P(n) \) is

\[ \exists n \in S, \sim P(n): \text{There exists } n \in S \text{ such that } n^2 + n + 1 \text{ is not prime.} \]

is true as \( 7 \in S \) but \( 7^2 + 7 + 1 = 57 \) is not prime. On the other hand, the negation of \( \exists n \in S, P(n) \) is

\[ \forall n \in S, \sim P(n): \text{If } n \in S, \text{ then } n^2 + n + 1 \text{ is not prime.} \]

is false since, for example, \( 1 \in S \) and \( 1^2 + 1 + 1 = 3 \) is prime.

In Section 2.10 we began a discussion of quantified statements containing two quantifiers. We expand this discussion here.

**Example 8.2**  Consider

\[ P(s, t): 2^s + 3^t \text{ is prime.} \]

where \( s \) is a positive even integer and \( t \) is a positive odd integer. If we let \( S \) denote the set of positive even integers and \( T \) the set of positive odd integers, then the quantified statement

\[ \exists s \in S, \exists t \in T, P(s, t) \]

can be expressed in words as

There exist a positive even integer \( s \) and a positive odd integer \( t \) such that \( 2^s + 3^t \) is prime. \hspace{1cm} (8.1)

The statement (8.1) is true since

\[ P(2, 1): 2^2 + 3^1 = 7 \text{ is prime.} \]

is true. On the other hand, the quantified statement

\[ \forall s \in S, \forall t \in T, P(s, t) \]

can be expressed in words as

For every positive even integer \( s \) and every positive odd integer \( t, 2^s + 3^t \) is prime. \hspace{1cm} (8.2)

The statement (8.2) is false since

\[ P(6, 3): 2^6 + 3^3 = 91 \text{ is a prime.} \]

is false, as \( 91 = 7 \cdot 13 \) is not a prime. ♦
Let $P(s, t)$ be an open sentence, where the domain of the variable $s$ is $S$ and the domain of the variable $t$ is $T$. Recall that the negations of the quantified statements $\exists s \in S, \exists t \in T, P(s, t)$ and $\forall s \in S, \forall t \in T, P(s, t)$ are

$$\sim (\exists s \in S, \exists t \in T, P(s, t)) \equiv \forall s \in S, \forall t \in T, \sim P(s, t)$$

and

$$\sim (\forall s \in S, \forall t \in T, P(s, t)) \equiv \exists s \in S, \exists t \in T, \sim P(s, t).$$

Therefore, the negation of the statement (8.1) is

For every positive even integer $s$ and every positive odd integer $t$, $2s + 3t$ is not prime.

which is a false statement. On the other hand, the negation of the statement (8.2) is

There exist a positive even integer $s$ and a positive odd integer $t$ such that $2s + 3t$ is not prime.

which is a true statement.

We have seen that quantified statements may also contain different kinds of quantifiers. For example, it follows by the definition of an even integer that for every even integer $n$, there exists an integer $k$ such that $n = 2k$. There is another mathematical symbol with which you should be familiar. The symbol $\ni$ denotes the phrase such that (although some mathematicians simply write s.t. for “such that”). For example, let $S$ denote the set of even integers again. Then

$$\forall n \in S, \exists k \in \mathbb{Z} \ni n = 2k \quad (8.3)$$

states:

For every even integer $n$, there exists an integer $k$ such that $n = 2k$.

This statement can be reworded as:

If $n$ is an even integer, then $n = 2k$ for some integer $k$.

If we interchange the two quantifiers in (8.3), we obtain, in words:

There exists an even integer $n$ such that for every integer $k$, $n = 2k$.

This statement can also be reworded as

There exists an even integer $n$ such that $n = 2k$ for every integer $k$.

This statement can be expressed in symbols as

$$\exists n \in S, \forall k \in \mathbb{Z}, n = 2k. \quad (8.4)$$

Certainly, the statements (8.3) and (8.4) say something totally different. Indeed, (8.3) is true and (8.4) is false.

Another such example of this is

For every real number $x$, there exists an integer $n$ such that $|x - n| < 1$. \quad (8.5)

This statement can also be expressed as

If $x$ is a real number, then there exists an integer $n$ such that $|x - n| < 1$.  

In order to state (8.5) in symbols, let
\[ P(x, n): |x - n| < 1 \]
where the domain of the variable \( x \) is \( \mathbb{R} \) and the domain of the variable \( n \) is \( \mathbb{Z} \). Thus, (8.5) can be expressed in symbols as
\[ \forall x \in \mathbb{R}, \exists n \in \mathbb{Z}, P(x, n). \] The statement (8.5) is true, as we now verify. In the proof of the following result, we will refer to the ceiling \( \lceil x \rceil \) of a real number, which is the smallest integer greater than or equal to \( x \).

**Result 8.3** For every real number \( x \), there exists an integer \( n \) such that \( |x - n| < 1 \).

**Proof** Let \( x \) be a real number. If we let \( n = \lceil x \rceil \), then \( |x - n| = |x - \lceil x \rceil| = \lceil x \rceil - x < 1 \).

Another example of a quantified statement containing two different quantifiers is

There exists a positive even integer \( m \) such that for every positive integer \( n \),
\[ \left| \frac{1}{m} - \frac{1}{n} \right| \leq \frac{1}{2}. \] (8.6)

Let \( S \) denote the set of positive even integers and let
\[ P(m, n): \left| \frac{1}{m} - \frac{1}{n} \right| \leq \frac{1}{2}. \]
where the domain of the variable \( m \) is \( S \) and the domain of the variable \( n \) is \( \mathbb{N} \). Thus, (8.6) can be expressed in symbols as
\[ \exists m \in S, \forall n \in \mathbb{N}, P(m, n). \] The truth of the statement (8.6) is now verified.

**Result 8.4** There exists a positive even integer \( m \) such that for every positive integer \( n \),
\[ \left| \frac{1}{m} - \frac{1}{n} \right| \leq \frac{1}{2}. \]

**Proof** Consider \( m = 2 \). Let \( n \) be a positive integer. We consider three cases.

**Case 1.** \( n = 1 \). Then \( \left| \frac{1}{2} - \frac{1}{1} \right| = \left| \frac{1}{2} - 1 \right| = \frac{1}{2} \).

**Case 2.** \( n = 2 \). Then \( \left| \frac{1}{2} - \frac{1}{2} \right| = \left| \frac{1}{2} - \frac{1}{2} \right| = 0 < \frac{1}{2} \).

**Case 3.** \( n \geq 3 \). Then \( \left| \frac{1}{2} - \frac{1}{n} \right| = \left| \frac{1}{2} - \frac{1}{n} \right| = \frac{1}{2} - \frac{1}{n} < \frac{1}{2} \).

Thus, \( \left| \frac{1}{2} - \frac{1}{n} \right| \leq \frac{1}{2} \) for every \( n \in \mathbb{N} \).

Let \( P(s, t) \) be an open sentence, where the domain of the variable \( s \) is \( S \) and the domain of the variable \( t \) is \( T \). The negation of the quantified statement \( \forall s \in S, \exists t \in T, P(s, t) \) is
\[ \sim (\forall s \in S, \exists t \in T, P(s, t)) \equiv \exists s \in S, \sim (\exists t \in T, P(s, t)) \equiv \exists s \in S, \forall t \in T, \sim P(s, t); \]
while the negation of the quantified statement $\exists s \in S, \forall t \in T, P(s, t)$ is

$$
\sim (\exists s \in S, \forall t \in T, P(s, t)) \equiv \forall s \in S, (\sim (\forall t \in T, P(s, t))
$$

$$
\equiv \forall s \in S, \exists t \in T, \sim P(s, t).
$$

Consequently, the negation of the statement (8.5) is

There exists a real number $x$ such that for every integer $n$, $|x - n| \geq 1$.

This statement is therefore false. The negation of the statement (8.6) is

For every positive even integer $m$, there exists a positive integer $n$ such that $|\frac{1}{m} - \frac{1}{n}| > \frac{1}{2}$.

This too is false.

Let’s consider the following statement, which has more than two quantifiers.

For every positive real number $e$, there exists a positive real number $d$ such that for every real number $x$, $|x| < d$ implies that $|2x| < e$. (8.7)

If we let $P(x, d)$: $|x| < d$ and $Q(x, e)$: $|2x| < e$

where the domain of the variables $e$ and $d$ is $\mathbb{R}^+$ and the domain of the variable $x$ is $\mathbb{R}$, then (8.7) can be expressed in symbols as

$$
\forall e \in \mathbb{R}^+, \exists d \in \mathbb{R}^+, \forall x \in \mathbb{R}, P(x, d) \Rightarrow Q(x, e).
$$

The statement (8.7) is in fact true, which we now verify.

**Result 8.5**

For every positive real number $e$, there exists a positive real number $d$ such that if $x$ is a real number with $|x| < d$, then $|2x| < e$.

**Proof**

Let $e$ be a positive real number. Now choose $d = e/2$. Let $x$ be a real number with $|x| < d = e/2$. Then

$$
|2x| = 2|x| < 2d = 2 \left( \frac{e}{2} \right) = e,
$$

as desired. $\blacksquare$

**SECTION 8.2 EXERCISES**

8.10. (a) Express the following quantified statement in symbols:

For every odd integer $n$, the integer $3n + 1$ is even.

(b) Prove that the statement in (a) is true.

8.11. (a) Express the following quantified statement in symbols:

There exists a positive even integer $n$ such that $3n + 2^{n-2}$ is odd.

(b) Prove that the statement in (a) is true.
210 Chapter 8 Prove or Disprove

8.12. (a) Express the following quantified statement in symbols:
   *For every positive integer n, the integer \( n^{n-1} \) is even.*
   (b) Show that the statement in (a) is false.

8.13. (a) Express the following quantified statement in symbols:
   *There exists an integer n such that \( 3n^2 - 5n + 1 \) is an even integer.*
   (b) Show that the statement in (a) is false.

8.14. (a) Express the following quantified statement in symbols:
   *For every integer \( n \geq 2 \), there exists an integer m such that \( n < m < 2n \).*
   (b) Prove that the statement in (a) is true.

8.15. (a) Express the following quantified statement in symbols:
   *There exists an integer n such that \( m(n-3) \leq 1 \) for every integer m.*
   (b) Prove that the statement in (a) is true.

8.16. (a) Express the following quantified statement in symbols:
   *For every integer n, there exists an integer m such that \( (n-2)(m-2) > 0 \).*
   (b) Express in symbols the negation of the statement in (a).
   (c) Show that the statement in (a) is false.

8.17. (a) Express the following quantified statement in symbols:
   *There exists a positive integer n such that \( -mn < 0 \) for every integer m.*
   (b) Express in symbols the negation of the statement in (a).
   (c) Show that the statement in (a) is false.

8.18. (a) Express the following quantified statement in symbols:
   *For every positive integer a, there exists an integer b with \( |b| < a \) such that \( |bx| < a \) for every real number x.*
   (b) Prove that the statement in (a) is true.

8.19. (a) Express the following quantified statement in symbols:
   *For every real number x, there exist integers a and b such that \( a \leq x \leq b \) and \( b - a = 1 \).*
   (b) Prove that the statement in (a) is true.

8.20. (a) Express the following quantified statement in symbols:
   *There exists an integer n such that for two real numbers x and y, \( x^2 + y^2 \geq n \).*
   (b) Prove that the statement in (a) is true.

8.21. (a) Express the following quantified statement in symbols:
   *For every even integer \( a \) and odd integer \( b \), there exists a rational number c such that either \( a < c < b \) or \( b < c < a \).*
   (b) Prove that the statement in (a) is true.

8.22. (a) Express the following quantified statement in symbols:
   *There exist two integers a and b such that for every positive integer n, \( a < \frac{1}{n} < b \).*
   (b) Prove that the statement in (a) is true.

8.23. (a) Express the following quantified statement in symbols:
   *There exist odd integers a, b and c such that \( a + b + c = 1 \).*
   (b) Prove that the statement in (a) is true.

8.24. (a) Express the following quantified statement in symbols:
   *For every three odd integers a, b and c, their product abc is odd.*
   (b) Prove that the statement in (a) is true.
8.25. Consider the following statement.

\[ R : \text{There exists a real number } L \text{ such that for every positive real number } e, \text{ there exists a positive real number } d \text{ such that} \]
\[ \text{if } x \text{ is a real number with } |x| < d, \text{ then } |3x - L| < e. \]

(a) Use \( P(x, d) \): \( |x| < d \) and \( Q(x, L, e) \): \( |3x - L| < e \) to express the statement \( R \) in symbols.

(b) Prove that the statement \( R \) is true.

8.26. Prove the following statement. For every positive real number \( a \) and positive rational number \( b \), there exist a real number \( c \) and irrational number \( d \) such that \( ac + bd = 1 \).

8.27. Prove the following statement. For every integer \( a \), there exist integers \( b \) and \( c \) such that \( |a - b| > cd \) for every integer \( d \).

8.3 TESTING STATEMENTS

We now turn our attention to the main topic of this chapter. For a given statement whose truth value is not provided to us, our task is to determine the truth or falseness of the statement and, in addition, show that our conclusion is correct by proving or disproving the statement, as appropriate.

**Example 8.6** Prove or disprove: There is a real number solution of the equation
\[ x^6 + 2x^2 + 1 = 0. \]

**Strategy** Observe that \( x^6 \) and \( x^2 \) are even powers of \( x \). Thus, if \( x \) is any real number, then \( x^6 \geq 0 \) and \( x^2 \geq 0 \), so \( 2x^2 \geq 0 \). Adding 1 to \( x^6 + 2x^2 \) shows that \( x^6 + 2x^2 + 1 \geq 1 \). Hence, it is impossible for \( x^6 + 2x^2 + 1 \) to be 0. These thoughts lead us to our solution. We begin by informing the reader that the statement is false, so the reader knows what we will be trying to do.

\[ \Box \]

**Solution of Example 8.6** The statement is false. Let \( x \in \mathbb{R} \). Since \( x^6 \geq 0 \) and \( x^2 \geq 0 \), it follows that \( x^6 + 2x^2 + 1 \geq 1 \) and so \( x^6 + 2x^2 + 1 \neq 0 \). \[ \Box \]

For the preceding example, we wrote “Strategy” rather than “Proof Strategy” for two reasons: (1) Since the statement may be false, there may be no proof in this case. (2) We are essentially “thinking out loud,” trying to convince ourselves whether the statement is true or false. Of course, if the statement turns out to be true, then our strategy may very well turn into a proof strategy.

**Example 8.7** Prove or disprove: Let \( x, y, z \in \mathbb{Z} \). Then two of the integers \( x, y \) and \( z \) are of the same parity.

**Strategy** For any three given integers, either two are even or two are odd. So, it certainly seems as if the statement is true. The only question appears to be whether what we said in the preceding sentence is convincing enough to all readers. We try another approach. \[ \Box \]
212 Chapter 8  Prove or Disprove

Solution  The statement is true.

Proof  Consider $x$ and $y$. If $x$ and $y$ are of the same parity, then the proof is complete. Thus, we may assume that $x$ and $y$ are of opposite parity, say $x$ is even and $y$ is odd. If $z$ is even, then $x$ and $z$ are of the same parity; while if $z$ is odd, then $y$ and $z$ are of the same parity. ■

Of course, the preceding proof could have been done by cases as well.

Example 8.8  Prove or disprove: Let $A$, $B$ and $C$ be sets. If $A \times C = B \times C$, then $A = B$.

Strategy  The elements of the set $A \times C$ are ordered pairs of elements, namely they are of the form $(x, y)$, where $x \in A$ and $y \in C$. Let $(x, y) \in A \times C$. If $A \times C = B \times C$, then it follows that $(x, y)$ must be an element of $B \times C$ as well. This says that $x \in B$ and $y \in C$. Conversely, if $(x, y) \in B \times C$, then $(x, y) \in A \times C$, which implies that $x \in A$ as well. These observations certainly seem to suggest that it should be possible to show that $A = B$ under these conditions. However, this argument depends on $A \times C$ containing an element $(x, y)$. Could it happen that $A \times C$ contains no elements? If $A$ or $C$ is empty, this would happen. However, if $C \neq \emptyset$ and $A \times C = \emptyset$, then $A$ must be empty. But $B \times C = A \times C = \emptyset$ would mean that $B$ must also be empty and so $A = B$. This suggests a different response.

Solution of Example 8.8  The statement is false. Let $A = \{1\}$, $B = \{2\}$ and $C = \emptyset$. Then $A \times C = B \times C = \emptyset$, but $A \neq B$. Hence, these sets $A$, $B$ and $C$ form a counterexample. ■

In some instances, we might consider modifying a false statement so that the revised statement is true. Our preceding discussion seems to suggest that if the set $C$ were required to be nonempty, then the statement would have been true.

Result 8.9  Let $A$, $B$ and $C$ be sets, where $C \neq \emptyset$. If $A \times C = B \times C$, then $A = B$.

Proof  Assume that $A \times C = B \times C$. Since $C \neq \emptyset$, the set $C$ contains some element $c$. Let $x \in A$. Then $(x, c) \in A \times C$. Since $A \times C = B \times C$, it follows that $(x, c) \in B \times C$. Hence, $x \in B$ and so $A \subseteq B$. By a similar argument, it follows that $B \subseteq A$. Thus, $A = B$. ■

Example 8.10  Prove or disprove: There exists a real number $x$ such that $x^3 < x < x^2$.

Strategy  If there is a real number $x$ such that $x^3 < x < x^2$, then this number is certainly not 0. Consequently, any real number $x$ with this property is either positive or negative. If $x > 0$, then we can divide $x^3 < x < x^2$ by $x$, obtaining $x^2 < 1 < x$. However, if $x > 1$, then $x^2 > 1$. Therefore, there is no positive real number $x$ for which $x^3 < x < x^2$. Hence, any real number $x$ satisfying $x^3 < x < x^2$ must be negative. Dividing $x^3 < x < x^2$ by $x$ gives us $x^2 > 1 > x$ or $x < 1 < x^2$. Experimenting with some negative numbers tells us that any number less than $-1$ has the desired property. ■

Solution of Example 8.10  The statement is true.

Proof  Consider $x = -2$. Then $x^3 = -8$ and $x^2 = 4$. Thus, $x^3 < x < x^2$. ■
Example 8.11  Prove or disprove: For every positive irrational number \( b \), there exists an irrational number \( a \) such that \( 0 < a < b \).

**Strategy**  We begin with a positive irrational number \( b \). If this statement is true, then we must show that there is an irrational number \( a \) such that \( 0 < a < b \). If we let \( a = b/2 \), then certainly \( 0 < a < b \). The only question is whether \( b/2 \) is necessarily irrational. We have seen, however, that \( b/2 \) is irrational (in Exercise 5.18 in Section 5.2).

♦

**Solution of Example 8.11**  The statement is true.

**Proof**  Let \( b \) be a positive irrational number. Now let \( a = b/2 \). Then \( 0 < a < b \) and \( a \) is irrational by Exercise 5.18.

Example 8.12  Prove or disprove: Every even integer is the sum of three distinct even integers.

**Strategy**  This statement can be reworded in a variety of ways. One rewording of this statement is: If \( n \) is an even integer, then there exist three distinct even integers \( a \), \( b \) and \( c \) such that \( n = a + b + c \). What this statement does not say is that the sum of three distinct even integers is even; that is, we do not begin with three distinct even integers and show that their sum is even. We begin with an even integer \( n \) and ask whether we can find three distinct even integers \( a \), \( b \) and \( c \) such that \( n = a + b + c \). This is certainly true for \( n = 0 \) since \( 0 = (-2) + 0 + 2 \). It is also true for \( n = 2 \) since \( 2 = (-2) + 0 + 4 \). If \( n = 4 \), then \( 4 = (-2) + 2 + 4 \). This last example may suggest a proof in general. For every even integer \( n \), we can write \( n = 2 + (-2) + n \). Certainly, \( n \), \( 2 \) and \( -2 \) are even. But are they distinct? They are not distinct if \( n = 2 \) or \( n = -2 \). This provides a plan for a proof.

♦

**Solution of Example 8.12**  The statement is true.

**Proof**  Let \( n \) be an even integer. We show that \( n \) is the sum of three distinct even integers by considering the following three cases.

Case 1. \( n = 2 \). Observe that \( 2 = (-2) + 0 + 4 \).

Case 2. \( n = -2 \). Observe that \( -2 = (-4) + 0 + 2 \).

Case 3. \( n \neq 2, -2 \). Then \( n = 2 + (-2) + n \).

Example 8.13  Prove or disprove: Let \( k \in \mathbb{N} \). If \( k^2 + 5k \) is odd, then \((k + 1)^2 + 5(k + 1) \) is odd.

**Strategy**  One idea that might occur to us is to assume that \( k^2 + 5k \) is an odd integer, where \( k \in \mathbb{N} \), and see if we can show that \((k + 1)^2 + 5(k + 1) \) is also odd. If \( k^2 + 5k \) is odd, then we can write \( k^2 + 5k = 2\ell + 1 \) for some integer \( \ell \). Then

\[
(k + 1)^2 + 5(k + 1) = k^2 + 2k + 1 + 5k + 5 = (k^2 + 5k) + (2k + 6)
\]

\[
= (2\ell + 1) + (2k + 6) = (2\ell + 2k + 6) + 1
\]

\[
= 2(\ell + k + 3) + 1,
\]

which is an odd integer and we have a proof.

♦
Chapter 8  Prove or Disprove

**Solution of Example 8.13**

The statement is true.

**Proof**

Assume that \( k^2 + 5k \) is an odd integer, where \( k \in \mathbb{N} \). Then \( k^2 + 5k = 2\ell + 1 \) for some integer \( \ell \). Hence,

\[
(k + 1)^2 + 5(k + 1) = k^2 + 2k + 1 + 5k + 5 = (k^2 + 5k) + (2k + 6) \\
= (2\ell + 1) + (2k + 6) = (2\ell + 2k + 6) + 1 \\
= 2(\ell + k + 3) + 1.
\]

Since \( \ell + k + 3 \) is an integer, \( (k + 1)^2 + 5(k + 1) \) is an odd integer.  

**Example 8.14**

Prove or disprove: For every positive integer \( n \), \( n^2 + 5n \) is an odd integer.

**Strategy**

What seems like a reasonable thing to do is to investigate \( n^2 + 5n \) for a few values of \( n \). For \( n = 1 \), we have \( n^2 + 5n = 1 + 5 \cdot 1 = 6 \). We have already solved the problem! For \( n = 1 \), \( n^2 + 5n \) is not an odd integer. We have discovered a counterexample.  

**Solution of Example 8.14**

The statement is false. For \( n = 1 \), \( n^2 + 5n = 1 + 5 \cdot 1 = 6 \), which is even. Thus, \( n = 1 \) is a counterexample.

Looking at Examples 8.13 and 8.14 again, we might be wondering what exactly is going on. Certainly, these two examples seem to be related. Perhaps the following thought may occur to us. For each positive integer \( n \), let

\[ P(n): \text{The integer } n^2 + 5n \text{ is odd}. \]

and consider the (quantified) statement

For every positive integer \( n \), \( n^2 + 5n \) is odd.

or in symbols,

\[ \forall n \in \mathbb{N}, P(n). \quad (8.8) \]

We might ask whether (8.8) is true. Because of the domain, a proof by induction seems appropriate. In fact, the statement in Example 8.13 is the inductive step in an induction proof of (8.8). By Example 8.13, the inductive step is true. On the other hand, the statement (8.8) is false as \( n = 1 \) is a counterexample. This emphasizes the importance of verifying both the basis step and the inductive step in an induction proof. Returning to Example 8.13 once again, we can show (using a proof by cases) that \( k^2 + 5k \) is even for every \( k \in \mathbb{N} \), which would provide a vacuous proof of the statement in Example 8.13.

In this chapter we have discussed analyzing statements, particularly understanding statements, determining whether they are true or false and proving or disproving them. All of the statements that we have analyzed were provided to us. But how do we obtain statements to analyze for ourselves? This is an important question and concerns the creative aspect of mathematics – how new mathematics is discovered. Obviously, there is no rule or formula for creativity but creating new statements often comes from studying old statements.
Let’s illustrate how we might create statements to analyze. In Exercise 4.6 in Chapter 4, you were asked to prove the following:

\[ \text{Let } a \in \mathbb{Z}. \text{ If } 3 \mid 2a, \text{ then } 3 \mid a. \] \hspace{1cm} (8.9)

What other statements does this suggest? For example, is its converse true? (The answer is yes, but the converse is not very interesting.) Is (8.9) true if 3 and 2 are interchanged? What integers can we replace 2 by in (8.9) and obtain a true statement? That is, for which positive integers \( k \) is it true that if \( 3 \mid ka \), then \( 3 \mid a \)? Of course, this is true for \( k = 1 \). And we know that it’s true for \( k = 2 \). It is not true for \( k = 3 \); that is, it is not true that if \( 3 \mid 3a \), then \( 3 \mid a \). The integer \( a = 1 \) is a counterexample. On the other hand, it is possible to prove that if \( 3 \mid 4a \), where \( a \in \mathbb{Z} \), then \( 3 \mid a \). What we are attempting to do is to extend the result in (8.9) so that we have a result of the type:

\[ \text{Let } a \in \mathbb{Z}. \text{ If } 3 \mid ka, \text{ then } 3 \mid a. \] \hspace{1cm} (8.10)

for a fixed integer \( k \) greater than 2. We would like to find a set \( S \) of positive integers such that the following is true:

\[ \text{Let } a \in \mathbb{Z}. \text{ If } k \in S, \text{ then } 3 \mid a. \] \hspace{1cm} (8.11)

Surely \( 2 \in S \). Result (8.9) then becomes a special case and a corollary of (8.11). For this reason (8.11) is called a \textbf{generalization} of (8.9). Ideally, we would like \( S \) to have the added property that (8.11) is true if \( k \in S \); while (8.11) is false if \( k \not\in S \). What we are seeking then is a set \( S \) of integers such that the following is true:

\[ \text{Let } a \in \mathbb{Z}. \text{ Then } 3 \mid ka \text{ implies that } 3 \mid a \text{ if and only if } k \in S. \]

If we were successful in finding this set \( S \), then we might start all over again by replacing \( 3 \) in (8.9) by some other positive integer.

In mathematics it is often the case that a new result is obtained by looking at an old result in a new way and extending it to obtain a generalization of the old result. Hence, it frequently happens that: \textit{Today’s theorem becomes tomorrow’s corollary.}

We conclude this chapter with a quiz consisting of fifteen “prove or disprove” problems. Solutions to these problems are given following the quiz.

\textbf{Quiz} Prove or disprove each of the following statements.

1. There are integer solutions to the equation \( x^2 + y^2 = 1 \); in particular, \( 1^2 + 0^2 = (-1)^2 + 0^2 = 0^2 + 1^2 = 0^2 + (-1)^2 = 1 \). If \( x, y \) is a real solution to the equation \( x^2 + y^2 = 1 \) that is not an integer solution, then \( x \) and \( y \) are both irrational.

2. A well-known number dealing with a positive integer \( n \) is \( \binom{n}{2} \), which is \( n(n - 1)/2 \). (The number \( \binom{n}{2} \) equals the number of 2-element subsets of an \( n \)-element set.) If \( \binom{n}{2} \) is a perfect square, that is, if \( \binom{n}{2} = a^2 \) for some positive integer \( a \), then \( a = 1 \).

3. Let \( A \) be a finite set with \( n \geq 1 \) elements. If we are given a set \( S \) of subsets of \( A \) such that \( |S| \geq 2^{n-1} \), then we can determine the set \( A \).

4. For each irrational number \( r \), there exists an irrational number \( s \) such that \( rs \) is a rational number.
5. Let \( a, b, c \in \mathbb{N} \). There exists an integer \( k \geq 2 \) such that the number of pairs of integers in \( \{ka, kb, kc\} \) of opposite parity equals the number of pairs of integers in \( S = \{a, b, c\} \) of opposite parity.

6. For each irrational number \( r \), there exists a positive integer \( N \) such that \( r^n \) is a rational number for all integers \( n \geq N \).

7. According to Fermat’s Last Theorem, for every three distinct positive integers \( a, b, c \), there exists no integer \( n \geq 3 \) such that \( a^n + b^n = c^n \). For every three distinct positive integers \( a, b, c \), there exists no positive integer \( n \) such that \( n^a + n^b = n^c \).

8. For every nonnegative integer \( n \), \( 3 \nmid (2^n + 5^n) \).

9. If \( a, b, c \) are any three distinct positive integers such that \( \frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 1 \), then \( a + b + c \) is a prime.

10. There exist positive integers \( a \) and \( b \) for which each is a multiple of both 2 and 3 and such that \( a/2 \) exceeds \( b/3 \) and \( b/2 \) exceeds \( a/3 \).

11. If \( A \) and \( B \) are subsets of a universal set \( U \) such that \( A \not\subseteq B \) and \( B \not\subseteq A \), then \( \overline{A} \not\subseteq \overline{B} \) and \( \overline{B} \not\subseteq \overline{A} \).

12. There exist distinct irrational numbers \( a \) and \( b \) such that \( a + b, ab \) and \( \frac{a}{b} \) are
   (a) three distinct rational numbers.
   (b) three distinct irrational numbers.
   (c) one rational number and two distinct irrational numbers.
   (d) one irrational number and two distinct rational numbers.

13. For every two sets \( A \) and \( B \), \( \mathcal{P}(A \cap B) = \mathcal{P}(A) \cap \mathcal{P}(B) \).

14. The numbers \(-3, -1, 1, 3\) are four consecutive odd integers whose product is the perfect square \( 9 = 3^2 \). There is no other perfect square that is the product of four consecutive odd integers.

15. Let \( S = \{a, b, c, d, e\} \) be a set of five distinct integers. If 3 divides the sum of every two elements of \( S \), then 3 divides the sum of every three elements of \( S \).

Solutions for Quiz

1. The statement is false. Let \( x = \frac{\sqrt{3}}{2} \) and \( y = \frac{1}{2} \). Then \( x \) is irrational, \( y \) is rational and \( x^2 + y^2 = 1 \). That is, \( (\frac{\sqrt{3}}{2}, \frac{1}{2}) \) is a point on the circle whose equation is \( x^2 + y^2 = 1 \).

2. The statement is false. If \( n = 9 \), then \( \binom{n}{2} = (9 \cdot 8)/2 = 36 = 6^2 \) and \( a = 6 \neq 1 \).

3. The statement is false. Let \( A = \{1, 2, a\} \) and let \( S = \{\emptyset, \{1\}, \{2\}, \{1, 2\}\} \). Then \( n = 3 \) and \( |S| = 2^3 - 1 = 4 \) and we cannot determine the element \( a \) in the set \( A \).

4. The statement is true.

**Proof** If \( r \) is an irrational number, then \( s = \frac{1}{r} \) is also irrational and \( rs = 1 \) is rational.

5. The statement is true.
8.3 Testing Statements 217

Proof Let \( k \geq 3 \) be any odd positive integer. Then \( kx \) is odd if and only if \( x \) is odd for each \( x \in S \). Thus, the number of pairs of integers in \( \{ka, kb, kc\} \) of opposite parity equals the number of pairs of integers in \( S \) of opposite parity.

6. The statement is false. For example, \( r = \sqrt{2} \) is irrational. Let \( n = 2k + 1 \) be an odd integer for some positive integer \( k \). Then \( r^n = (\sqrt{2})^{2k+1} = 2^k \sqrt{2} \) is irrational. Hence, there is no positive integer \( N \) such that \( r^n \) is a rational number for all integers \( n \geq N \).

7. The statement is true.

Proof Let \( a, b, c \) be three distinct positive integers. Assume, to the contrary, that there exists a positive integer \( n \) such that \( n^a + n^b = n^c \). Certainly, \( n \neq 1 \); thus, \( n \geq 2 \). Necessarily, \( c \) is the largest of the three integers \( a, b, c \). We may assume that \( a < b < c \). Dividing \( n^a + n^b = n^c \) by \( n^a \), we obtain \( 1 + n^{b-a} = n^{c-a} \). Hence, \( n^{c-a} - n^{b-a} = 1 \) and so \( n^{b-a}(n^{c-b} - 1) = 1 \). Also, \( n[n^{b-a-1}(n^{c-b} - 1)] = 1 \). Since \( n^{b-a-1}(n^{c-b} - 1) \in \mathbb{Z} \), it follows that \( n \mid 1 \). This is a contradiction.

8. The statement is true.

Proof We proceed by induction. Since \( 2^0 + 5^0 = 2 \) and \( 3 \nmid 2 \), the statement is true for \( n = 0 \). Assume that \( 3 \nmid (2^k + 5^k) \) for some nonnegative integer \( k \). We show that \( 3 \nmid (2^{k+1} + 5^{k+1}) \). Since \( 3 \nmid (2^k + 5^k) \), it follows that \( 2^k + 5^k = 3q + r \), where \( q \in \mathbb{Z} \) and \( r \in \{1, 2\} \). Then \( 5^k = 3q + r - 2^k \). Observe that

\[
2^{k+1} + 5^{k+1} = 2 \cdot 2^k + 5 \cdot 5^k = 2 \cdot 2^k + 5(3q + r - 2^k)
\]

\[
= 2 \cdot 2^k + 15q + 5r - 5 \cdot 2^k = 15q - 3 \cdot 2^k + 3r + 2r
\]

\[
= 3(5q - 2^k + r) + 2r.
\]

Since \( 5q - 2^k + r \in \mathbb{Z} \) and \( 3 \nmid 2r \), it follows that \( 3 \nmid (2^{k+1} + 5^{k+1}) \). By the Principle of Mathematical Induction, \( 5 \nmid (2^n + 3^n) \) for every nonnegative integer \( n \).

9. The statement is true.

Proof Let \( a, b, c \) be three distinct positive integers such that \( \frac{1}{a} + \frac{1}{b} + \frac{1}{c} = 1 \). We may assume that \( a < b < c \). So \( \frac{1}{a} > \frac{1}{b} > \frac{1}{c} \). In particular, \( \frac{1}{a} > \frac{1}{3} \), which implies that \( a = 2 \). Since \( \frac{1}{b} > \frac{1}{4} \) and \( b \neq 2 \), it follows that \( b = 3 \). Thus, \( \frac{1}{a} = 1 - \frac{1}{2} = \frac{1}{2} \) and so \( c = 6 \). Therefore, \( a = 2 \), \( b = 3 \) and \( c = 6 \); thus, \( a + b + c = 11 \) is a prime.

10. The statement is true.

Proof The integers \( a = 24 \) and \( b = 18 \) have the desired properties.

11. The statement is true.

Proof Suppose that \( A \not\subseteq B \). Then there is \( a \in A \) such that \( a \notin B \). Thus, \( a \in \overline{B} \). Since \( a \in A \), it follows that \( a \notin \overline{A} \). Hence, \( \overline{A} \not\subseteq \overline{B} \). Similarly, if \( B \not\subseteq A \), then \( \overline{B} \not\subseteq \overline{A} \).

12. The statement is true.

(a) \( a = \sqrt{2} \) and \( b = -\sqrt{2} \).

(b) \( a = \sqrt{2} \) and \( b = \sqrt{3} \).

(c) \( a = \sqrt{2} + 1 \) and \( b = \sqrt{2} - 1 \).

(d) \( a = \sqrt{2} \) and \( b = 2\sqrt{2} \).
13. The statement is true.

**Proof** First, we show that \( \mathcal{P}(A \cap B) \subseteq \mathcal{P}(A) \cap \mathcal{P}(B) \). Since \( A \cap B \subseteq A \) and \( A \cap B \subseteq B \), it follows that \( \mathcal{P}(A \cap B) \subseteq \mathcal{P}(A) \) and \( \mathcal{P}(A \cap B) \subseteq \mathcal{P}(B) \). Hence, 
\[ \mathcal{P}(A \cap B) \subseteq \mathcal{P}(A) \cap \mathcal{P}(B). \]

Next, we show that \( \mathcal{P}(A) \cap \mathcal{P}(B) \subseteq \mathcal{P}(A \cap B) \). Let \( S \in \mathcal{P}(A) \cap \mathcal{P}(B) \). Then \( S \in \mathcal{P}(A) \) and \( S \in \mathcal{P}(B) \). So, \( S \) is a subset of \( A \) and \( S \) is a subset of \( B \). Hence, \( S \subseteq A \cap B \) and so \( S \in \mathcal{P}(A \cap B) \). Therefore, \( \mathcal{P}(A) \cap \mathcal{P}(B) \subseteq \mathcal{P}(A \cap B) \).

Since \( \mathcal{P}(A \cap B) \subseteq \mathcal{P}(A) \cap \mathcal{P}(B) \) and \( \mathcal{P}(A) \cap \mathcal{P}(B) \subseteq \mathcal{P}(A \cap B) \), it follows that \( \mathcal{P}(A \cap B) = \mathcal{P}(A) \cap \mathcal{P}(B) \).

14. The statement is true.

**Proof** Let \( x - 3, x - 1, x + 1, x + 3 \) be four consecutive odd integers whose product is \( a^2 \). Then
\[
(x - 3)(x - 1)(x + 1)(x + 3) = (x^2 - 1)(x^2 - 9) = x^4 - 10x^2 + 9 = a^2.
\]

Therefore, \( x^4 - 10x^2 + (9 - a^2) = 0 \). By the quadratic formula,
\[
x^2 = \frac{10 \pm \sqrt{100 - 4(9 - a^2)}}{2} = \frac{10 \pm \sqrt{4a^2 + 16}}{2} = 5 \pm \sqrt{a^2 + 4}.
\]

Thus, \( b = \sqrt{a^2 + 4} \) is an integer and so \( b^2 = a^2 + 16 \). Hence,
\[
b^2 - a^2 = (b + a)(b - a) = 16.
\]

Since \( b \in \mathbb{N} \) and \( b + a > b - a \), it follows that \( b + a = 8 \) and \( b - a = 2 \), which implies that \( b = 5 \) and \( a = 3 \) is the only solution.

15. The statement is true.

**Proof** Consider any three elements of \( S \), say \( a, b, c \in S \). We show that \( 3 \mid (a + b + c) \). Since \( 3 \) divides the sum of every two elements of \( S \), it follows that \( 3 \mid (a + b), 3 \mid (a + c) \) and \( 3 \mid (b + c) \). Hence, \( 3 \) divides \( (a + b) + (a + c) + (b + c) = 2(a + b + c) = 2x \), where \( x = a + b + c \in \mathbb{Z} \). Since \( 3 \mid 2x \) and \( 3 \mid 2 \), it follows from Result 4.8 that \( 3 \mid x \) and so \( 3 \mid (a + b + c) \).

Note: It therefore follows that \( 3 \) divides the sum of every \( k \) elements of \( S \) for every integer \( k \) with \( 1 \leq k \leq 5 \).

### SECTION 8.3 EXERCISES

8.28. For the set \( S = \{1, 2, 3, 4\} \), let
\[
P(n): 2^{n+1} + (-1)^{n+1} (2^n + 2^{n-1}) \text{ is prime.} \quad Q(n): 2n + 3 \text{ is prime.}
\]

Prove or disprove: \( \forall n \in S, P(n) \Rightarrow Q(n) \).
8.29. Let \( P(n): n^2 + 3n + 1 \) is even. Prove or disprove:

(a) \( \forall k \in \mathbb{N}, P(k) \Rightarrow P(k + 1) \).

(b) \( \forall n \in \mathbb{N}, P(n) \).

For each of the exercises 8.30–8.81: Prove or disprove.

8.30. Let \( x \in \mathbb{Z} \). If \( 4x + 7 \) is odd, then \( x \) is even.

8.31. For every nonnegative integer \( n \), there exists a nonnegative integer \( k \) such that \( k < n \).

8.32. Every even integer can be expressed as the sum of two odd integers.

8.33. If \( x, y, z \in \mathbb{Z} \) such that \( x + y + z = 101 \), then two of the integers \( x, y \) and \( z \) are of opposite parity.

8.34. For every two sets \( A \) and \( B \), \( (A \cup B) - B = A \).

8.35. Let \( A \) be a set. If \( A \cap B = \emptyset \) for every set \( B \), then \( A = \emptyset \).

8.36. There exists an odd integer, the sum of whose digits is even and the product of whose digits is odd.

8.37. For every nonempty set \( A \), there exists a set \( B \) such that \( A \cup B = \emptyset \).

8.38. If \( x \) and \( y \) are real numbers, then \( |x + y| = |x| + |y| \).

8.39. Let \( S \) be a nonempty set. For every proper subset \( A \) of \( S \), there exists a nonempty subset \( B \) of \( S \) such that \( A \cup B = S \) and \( A \cap B = \emptyset \).

8.40. There is a real number solution of the equation \( x^4 + x^2 + 1 = 0 \).

8.41. There exists an integer \( a \) such that \( a \cdot c \geq 0 \) for every integer \( c \).

8.42. There exist real numbers \( a, b \) and \( c \) such that \( \frac{a + b}{a + c} = \frac{b}{c} \).

8.43. If \( x, y \in \mathbb{R} \) and \( x^2 < y^2 \), then \( x < y \).

8.44. Let \( x, y, z \in \mathbb{Z} \). If \( z = x - y \) and \( z \) is even, then \( x \) and \( y \) are odd.

8.45. Every odd integer can be expressed as the sum of three odd integers.

8.46. Let \( x, y, z \in \mathbb{Z} \). If \( z = x + y \) and \( x \) is odd, then \( y \) is even and \( z \) is odd.

8.47. For every two integers \( a \) and \( c \), there exists an integer \( b \) such that \( a + b = c \).

8.48. Every even integer can be expressed as the sum of two even integers.

8.49. For every two rational numbers \( a \) and \( b \) with \( a < b \), there exists a rational number \( r \) such that \( a < r < b \).

8.50. Let \( A, B, C \) and \( D \) be sets with \( A \subseteq C \) and \( B \subseteq D \). If \( A \) and \( B \) are disjoint, then \( C \) and \( D \) are disjoint.

8.51. Let \( A \) and \( B \) be sets. If \( A \cup B \neq \emptyset \), then both \( A \) and \( B \) are nonempty.

8.52. For every two positive integers \( a \) and \( c \), there exists a positive integer \( b \) such that \( a + b = c \).

8.53. For every odd integer \( a \), there exist integers \( b \) and \( c \) of opposite parity such that \( a + b = c \).

8.54. For every rational number \( a/b \), where \( a, b \in \mathbb{N} \), there exists a rational number \( c/d \), where \( c \) and \( d \) are positive odd integers, such that \( 0 < \frac{c}{d} < \frac{a}{b} \).

8.55. The equation \( x^3 + x^2 - 1 = 0 \) has a real number solution between \( x = 0 \) and \( x = 1 \).

8.56. There exists a real number \( x \) such that \( x^2 < x < x^3 \).

8.57. Let \( A \) and \( B \) be sets. If \( A - B = B - A \), then \( A - B = \emptyset \).

8.58. If \( x \in \mathbb{Z} \), then \( x^{\frac{1}{x^2 - 1}} = x^{\frac{1}{x^2 - 1}} \).

8.59. For every positive rational number \( b \), there exists an irrational number \( a \) with \( 0 < a < b \).

8.60. Let \( A \) be a set. If \( A - B = \emptyset \) for every set \( B \), then \( A = \emptyset \).

8.61. Let \( A, B \) and \( C \) be sets. If \( A \cap B = A \cap C \), then \( B = C \).
Chapter 8 Prove or Disprove

8.62. For every nonempty set $A$, there exists a set $B$ such that $|A - B| = |B - A|$.

8.63. Let $A$ be a set. If $A \cup B \neq \emptyset$ for every set $B$, then $A \neq \emptyset$.

8.64. There exist an irrational number $a$ and a rational number $b$ such that $a^b$ is irrational.

8.65. There exists a real number solution of the equation $x^2 + x + 1 = 0$.

8.66. For every two sets $A$ and $B$, $\mathcal{P}(A \cup B) = \mathcal{P}(A) \cup \mathcal{P}(B)$.

8.67. Every nonzero rational number can be expressed as the product of two irrational numbers.

8.68. Let $S$ be a set containing at least two elements. For every proper nonempty subset $A$ of $S$, there exists a proper nonempty subset $B$ of $S$ such that $A$ and $B$ are disjoint.

8.69. Let $S$ be a nonempty set and let $T$ be a collection of subsets of $S$. If $A \cap B \neq \emptyset$ for all pairs $A$, $B$ of elements of $T$, then there exists an element $x \in S$ such that $x \in C$ for all $C \in T$.

8.70. Let $A$, $B$ and $C$ be sets. Then $A \cup (B - C) = (A \cup B) - (A \cup C)$.

8.71. Let $a$, $b$, $c \in \mathbb{Z}$. If $ab$, $ac$ and $bc$ are even, then $a$, $b$ and $c$ are even.

8.72. Let $n \in \mathbb{Z}$. If $n^3 + n$ is even, then $n$ is even.

8.73. There exist three distinct integers $a$, $b$ and $c$ such that $a^b = b^c$.

8.74. Let $a$, $b$, $c \in \mathbb{Z}$. Then at least one of the numbers $a + b$, $a + c$ and $b + c$ is even.

8.75. Every integer can be expressed as the sum of two unequal integers.

8.76. There exist positive integers $x$ and $y$ such that $x^2 - y^2 = 101$.

8.77. For every positive integer $n$, $n^2 - n + 11$ is a prime.

8.78. For every odd prime $p$, there exist positive integers $a$ and $b$ such that $a^2 - b^2 = p$.

8.79. If the product of two consecutive integers is not divisible by 3, then their sum is.

8.80. The sum of every five consecutive integers is divisible by 5 and the sum of no six consecutive integers is divisible by 6.

8.81. There exist three distinct positive real numbers $a$, $b$, $c$, none of which are integers, such that all of $ab$, $ac$, $bc$ and $abc$ are integers.

Chapter 8 Supplemental Exercises

8.82. (a) Show that the following statement is false: For every positive integer $x$, there exists a positive integer $y$ such that $x < y < x^2$.

(b) Make a small addition to the statement in (a) so that the new statement is true. Prove the new statement.

8.83. (a) Show that the following statement is false: Every positive integer is the sum of two distinct positive odd integers.

(b) Make a small addition to the statement in (a) so that the new statement is true. Prove the new statement.

8.84. (a) Prove or disprove: There exist two distinct positive integers whose sum exceeds their product.

(b) Your solution to (a) should suggest another problem to you. State and solve this new problem.
8.85. (a) Prove or disprove: If \(a\) and \(b\) are positive integers, then \(\sqrt{a + b} = \sqrt{a} + \sqrt{b}\).
(b) Prove or disprove: There exist positive real numbers \(a\) and \(b\) such that \(\sqrt{a + b} = \sqrt{a} + \sqrt{b}\).
(c) Complete the following statement so that it’s true and provide a proof:

Let \(a, b \in \mathbb{R}^+ \cup \{0\}\). Then \(\sqrt{a + b} = \sqrt{a} + \sqrt{b}\) if and only if

8.86. Consider the open sentence \(P(n) : n! > \left(\frac{n}{2}\right)^n\) for \(n \in \mathbb{N}\). Prove or disprove:

\(\forall n \in \mathbb{N}, P(n)\).

8.87. Evaluate the proof of the following statement.

Result Every even integer can be expressed as the sum of three distinct even integers.

Proof Let \(n\) be an even integer. Since \(n + 2, n - 2\) and \(-n\) are distinct even integers and

\[n = (n + 2) + (n - 2) + (-n),\]

the desired result follows.

8.88. It is known (although challenging to prove) that for every nonnegative integer \(m\),
the integer \(8m + 3\) can be expressed as \(a^2 + b^2 + c^2\) for positive integers \(a, b\) and \(c\).

(a) For every integer \(m\) with \(0 \leq m \leq 10\), find positive integers \(a, b\) and \(c\) such that
\(8m + 3 = a^2 + b^2 + c^2\).
(b) Prove or disprove: If \(a, b\) and \(c\) are positive integers such that
\(a^2 + b^2 + c^2 = 8m + 3\) for some integer \(m\), then all of \(a, b\) and \(c\) are odd.

8.89. In Exercise 4.6, you were asked to prove the statement

\[P: \text{Let } a \in \mathbb{Z}. \text{ If } 3 \mid 2a, \text{ then } 3 \mid a.\]

(a) Prove that the converse of \(P\) is true. Now state \(P\) and its converse in a more familiar manner.
(b) Is the statement obtained by interchanging 2 and 3 in \(P\) true?
(c) Find a set \(S\) of positive integers with \(2 \in S\) and \(|S| \geq 3\) such that the following is true:

Let \(a \in \mathbb{Z}. \text{ If } 3 \mid ka, \text{ where } k \in S, \text{ then } 3 \mid a.\)

Prove this generalization of the statement \(P\).
(d) In Result 4.8, it was shown for integers \(a\) and \(b\) that \(3 \mid ab\) if and only if \(3 \mid a\) or \(3 \mid b\). How can this be used to answer (c)?

8.90. In Exercise 5.22, you were asked to prove that \(\sqrt{2} + \sqrt{3}\) is irrational.

(a) Prove that \(\sqrt{2} + \sqrt{5}\) is irrational.
(b) Determine, with proof, another positive integer \(a\) such that \(\sqrt{2} + \sqrt{a}\) is irrational.
(c) State and prove a generalization of the result in (a).
222 Chapter 8 Prove or Disprove

8.91. In Exercise 3.27, you were asked to prove the statement:

\[ P: \text{If } n \in \mathbb{Z}, \text{ then } n^3 - n \text{ is even.} \]

This can be restated as:

\[ P: \text{If } n \in \mathbb{Z}, \text{ then } 2 \mid (n^3 - n). \]

(a) Find a positive integer \( a \neq 2 \) such that

\[ \text{If } n \in \mathbb{Z}, \text{ then } a \mid (n^3 - n). \]

is true and prove this statement.
(b) Find a positive integer \( k \neq 3 \) such that

\[ \text{If } n \in \mathbb{Z}, \text{ then } 2 \mid (n^k - n). \]

is true and prove this statement.
(c) Ask a question of your own dealing with \( P \) and provide an answer.

8.92. Let \( A \) denote the set of odd integers. Investigate the truth (or falseness) of the following statements.

(a) For all \( x, y \in A \), \( 2 \mid (x^2 + 3y^2) \).
(b) There exist \( x, y \in A \) such that \( 4 \mid (x^2 + 3y^2) \).
(c) For all \( x, y \in A \), \( 4 \mid (x^2 + 3y^2) \).
(d) There exist \( x, y \in A \) such that \( 8 \mid (x^2 + 3y^2) \).
(e) There exist \( x, y \in A \) such that \( 6 \mid (x^2 + 3y^2) \).
(f) Provide a related statement of your own and determine whether it is true or false.

8.93. (a) Prove or disprove the following: There exist four positive integers \( a, b, c \) and \( d \) such that \( a^2 + b^2 + c^2 = d^2 \).
(b) Prove or disprove the following: There exist four distinct positive integers \( a, b, c \) and \( d \) such that \( a^2 + b^2 + c^2 = d^2 \).
(c) The problems in (a) or (b) above should suggest another problem that you can solve. State and solve such a problem.
(d) The problems in (a) or (b) above should suggest a conjecture to you (that you probably cannot solve). State such a conjecture.

For each of the exercises 8.94–8.105: Prove or disprove.

8.94. If \( n \) is a positive integer and \( s \) is an irrational number, then \( n/s \) is an irrational number.

8.95. For every integer \( b \), there exists a positive integer \( a \) such that \( |a - |b|| \leq 1 \).

8.96. If \( x \) and \( y \) are integers of the same parity, then \( xy \) and \( (x + y)^2 \) are of the same parity.

8.97. Let \( a, b \in \mathbb{Z} \). If \( 6 \nmid ab \), then either (1) \( 2 \nmid a \) and \( 3 \nmid b \) or (2) \( 3 \nmid a \) and \( 2 \nmid b \).

8.98. For every positive integer \( n \), \( 2^n \geq 4^n \).

8.99. If \( A, B \) and \( C \) are sets, then \((A - B) \cup (A - C) = A - (B \cup C)\).

8.100. Let \( n \in \mathbb{N} \). If \((n + 1)(n + 4) \) is odd, then \((n + 1)(n + 4) + 3^n \) is odd.

8.101. (a) There exist distinct rational numbers \( a \) and \( b \) such that \( (a - 1)(b - 1) = 1 \).
(b) There exist distinct rational numbers \( a \) and \( b \) such that \( \frac{1}{a} + \frac{1}{b} = 1 \).
8.102. Let $a, b, c \in \mathbb{Z}$. If every two of $a, b$ and $c$ are of the same parity, then $a + b + c$ is even.

8.103. If $n$ is a nonnegative integer, then 5 divides $2 \cdot 4^n + 3 \cdot 9^n$.

8.104. Recall that there are $2^n$ subsets of an $n$-element set. For example, when $n = 4$, there are $2^4 = 16$ subsets of a 4-element set. Of these 16 subsets, 6 have two elements. When $n = 6$, there are $2^6 = 64$ subsets of a 6-element set. Of these 64 subsets, 15 have two elements and 15 have four elements, while 20 have three elements. The maximum number of subsets of an $n$-element set, $n \geq 3$, such that no two subsets are subsets of each other is \( \binom{n}{2} = \frac{n(n-1)}{2} \).

8.105. Let $n \in \mathbb{N}$. Then $5 \mid (2^n + 3^n)$ if and only if $n$ is odd.
Equivalence Relations

Two real numbers $x$ and $y$ can be related in a variety of ways. For example, (1) $x$ may be less than $y$, (2) $y$ may be 1 more than the square of $x$, or (3) $x$ and $y$ may be equal; in symbols,

\[(1) \ x < y, \ (2) \ y = x^2 + 1 \text{ or } (3) \ x = y.\]

In the case of integers $a$ and $b$, we could have

\[(1) \ a \mid b, \ (2) \ a \text{ and } b \text{ are of opposite parity} \text{ or } (3) \ a \equiv b \pmod{3}.\]

In the subject of geometry, a line $\ell$ in 3-space can be related to a plane $\Pi$ in 3-space if

\[(1) \ \ell \text{ lies on } \Pi, \ (2) \ \ell \text{ is parallel to } \Pi \text{ or } (3) \ \ell \text{ intersects } \Pi \text{ in exactly one point.}\]

A triangle $T$ can be related to a triangle $T'$ if

\[(1) \ T \text{ is congruent to } T', \ (2) \ T \text{ is similar to } T' \text{ or } (3) \ T \text{ has the same area as } T'.\]

In all of these examples, there are two sets $A$ and $B$ (where possibly $A = B$) and an element of $A$ is related to an element of $B$ in some manner. The topic of relations turns out to be important in mathematics. It is this topic we now turn to.

9.1 RELATIONS

When one refers to a relation $R$ from a set $A$ to a set $B$, we simply mean some subset of the Cartesian product $A \times B$ of $A$ and $B$. That is, the relation $R$ is a set of ordered pairs, where the first coordinate of the pair belongs to $A$ and the second coordinate belongs to $B$. Whenever the ordered pair $(a, b) \in R$, we say that $a$ is related to $b$ by $R$ and write $a \mathrel{R} b$. If the ordered pair $(a, b) \notin R$, then $a$ is not related to $b$ by $R$ and we write $a \not\mathrel{R} b$. For example, suppose that $A = \{x, y, z\}$ and $B = \{1, 2\}$ are two sets and we are considering the subset

\[R = \{(x, 2), (y, 1), (y, 2)\} \tag{9.1}\]

of $A \times B$. Hence, $R$ is a relation from $A$ to $B$. In this case, $x \mathrel{R} 2$ ($x$ is related to 2) and $x \not\mathrel{R} 1$ ($x$ is not related to 1). For any two sets $A$ and $B$, the sets $\emptyset$ and $A \times B$ are always subsets of $A \times B$ and so $\emptyset$ and $A \times B$ are relations from $A$ to $B$. (Indeed, these are the extreme
examples.) For the relation \( \emptyset \), no element of \( A \) is related to any element of \( B \); while for the relation \( A \times B \), each element of \( A \) is related to every element of \( B \). Simply said then, a relation from a set \( A \) to a set \( B \) tells us which elements of \( A \) are related to which elements of \( B \). Although this may seem like a fairly simple idea, it is nevertheless important that we have a thorough understanding of it. There is some terminology dealing with relations with which we need to be familiar.

Let \( R \) be a relation from set \( A \) to a set \( B \). By the **domain** of \( R \), which we denote by \( \text{dom}(R) \), is meant the subset of \( A \) defined by

\[
\text{dom}(R) = \{ a \in A : (a, b) \in R \text{ for some } b \in B \};
\]

while the **range** of \( R \), denoted by \( \text{range}(R) \), is the subset of \( B \) defined by

\[
\text{range}(R) = \{ b \in B : (a, b) \in R \text{ for some } a \in A \}.
\]

That is, \( \text{dom}(R) \) is that set of elements of \( A \) that occur as first coordinates among the ordered pairs in \( R \) and \( \text{range}(R) \) is the set of elements of \( B \) that occur as second coordinates among the ordered pairs in \( R \). The domain and range of the relation \( R \) given in (9.1) are \( \text{dom}(R) = \{ x, y \} \) and \( \text{range}(R) = \{ 1, 2 \} \). The reason that \( z \not\in \text{dom}(R) \) is because there is no ordered pair in \( R \) whose first coordinate is \( z \).

If \( R \) is a relation from a set \( A \) to a set \( B \), then the **inverse relation** of \( R \) is the relation \( R^{-1} \) from \( B \) to \( A \) defined by

\[
R^{-1} = \{(b, a) : (a, b) \in R \}.
\]

That is, to obtain \( R^{-1} \) from \( R \), the first and second coordinates of each ordered pair in \( R \) are interchanged. For example, the inverse relation of the relation \( R = \{(x, 2), (y, 1), (y, 2)\} \) from \( A = \{x, y, z\} \) to \( B = \{1, 2\} \) is the relation

\[
R^{-1} = \{(1, y), (2, x), (2, y)\}
\]

from \( B \) to \( A \).

By a **relation on a set** \( A \), we mean a relation from \( A \) to \( A \). That is, a relation on a single set \( A \) is a collection of ordered pairs whose first and second coordinates belong to \( A \). Therefore, \( \{(1, 2), (1, 3), (2, 2), (2, 3)\} \) is an example of a relation on the set \( A = \{1, 2, 3, 4\} \).

If \( A = \{1, 2\} \), then

\[
A \times A = \{(1, 1), (1, 2), (2, 1), (2, 2)\}.
\]

Since \( |A \times A| = 4 \), the number of subsets of \( A \times A \) is \( 2^4 = 16 \). Since a relation on \( A \) is, by definition, a subset of \( A \times A \), it follows that there are 16 relations on \( A \). Six of these 16 possible relations are

\[
\emptyset, \{(1, 2)\}, \{(1, 1), (1, 2)\}, \{(1, 2), (2, 1)\}, \{(1, 1), (1, 2), (2, 2)\}, A \times A.
\]

**SECTION 9.1 EXERCISES**

9.1. For the sets \( A = \{a, b, c\} \) and \( B = \{r, s, t, u\} \), let \( R = \{(a, s), (a, t), (b, t)\} \) be a relation from \( A \) to \( B \). Determine \( \text{dom}(R) \) and \( \text{range}(R) \).

9.2. Let \( A \) be a nonempty set and let \( B \) be a subset of the power set \( \mathcal{P}(A) \) of \( A \). Define a relation \( R \) from \( A \) to \( B \) by \( x \mathrel{R} Y \) if \( x \in Y \). Give an example of two sets \( A \) and \( B \) that illustrate this. What is \( R \) for these two sets?
Chapter 9  Equivalence Relations

9.3. Let \( A = \{0, 1\} \). Determine all the relations on \( A \).

9.4. Let \( A = \{a, b, c\} \) and \( B = \{1, 2, 3, 4\} \). Then \( R_1 = \{(a, 2), (a, 3), (b, 1), (b, 3), (c, 4)\} \) is a relation from \( A \) to \( B \), while \( R_2 = \{(1, b), (1, c), (2, a), (2, b), (3, c), (4, a), (4, c)\} \) is a relation from \( B \) to \( A \). A relation \( R \) is defined on \( A \) by \( x R y \) if there exists \( z \in B \) such that \( x R_1 z \) and \( z R_2 y \). Express \( R \) by listing its elements.

9.5. For the relation \( R = \{(1, 1), (1, 2), (1, 3), (2, 2), (2, 3), (3, 3)\} \) defined on the set \( \{1, 2, 3\} \), what is \( R^{-1} \)?

9.6. A relation \( R \) is defined on \( N \) by \( a R b \) if \( a / b \in N \). For \( c, d \in N \), under what conditions is \( c R^{-1} d \)?

9.7. Determine the inverse relation \( R^{-1} \) for the relation \( R = \{(x, y) : x + 4y \text{ is odd}\} \) defined on \( N \).

9.8. For the relation \( R = \{(x, y) : x \leq y\} \) defined on \( N \), what is \( R^{-1} \)?

9.9. Let \( A \) and \( B \) be sets with \( |A| = |B| = 4 \).

(a) Prove or disprove: If \( R \) is a relation from \( A \) to \( B \) where \( |R| = 9 \) and \( R = R^{-1} \), then \( A = B \).

(b) Show that by making a small change in the statement in (a), a different response to the resulting statement can be obtained.

9.10. Let \( A \) be a set with \( |A| = 4 \). What is the maximum number of elements that a relation \( R \) on \( A \) can contain so that \( R \cap R^{-1} = \emptyset \)?

9.2 PROPERTIES OF RELATIONS

If \( R \) is a relation defined on a single set \( A \), then there are three properties that \( R \) may possess and which will be of special interest to us.

A relation \( R \) defined on a set \( A \) is called **reflexive** if \( x R x \) for every \( x \in A \).

That is, \( R \) is reflexive if \( (x, x) \in R \) for every \( x \in A \).

In order to illustrate this and two other properties that we will soon describe, let \( S = \{a, b, c\} \) and consider the following six relations defined on \( S \):

\[
R_1 = \{(a, b), (b, a), (c, a)\}
\]

\[
R_2 = \{(a, b), (b, b), (b, c), (c, b), (c, c)\}
\]

\[
R_3 = \{(a, a), (a, c), (b, b), (c, a), (c, c)\}
\]

\[
R_4 = \{(a, a), (a, b), (b, b), (b, c), (a, c)\}
\]

\[
R_5 = \{(a, a), (a, b)\}
\]

\[
R_6 = \{(a, b), (a, c)\}.
\]

The relation \( R_1 \) is not reflexive since \( (a, a) \notin R_1 \), for example. Since \( (a, a) \notin R_2 \), it follows that \( R_2 \) is not reflexive either. In addition, none of the relations \( R_4, R_5, R_6 \) is reflexive. Because \( (a, a), (b, b), (c, c) \in R_3 \), the relation \( R_3 \) is reflexive, however.

Next, we consider a second important property that a relation on a single set may possess.

A relation \( R \) defined on a set \( A \) is called **symmetric** if whenever \( x R y \), then \( y R x \) for all \( x, y \in A \).

Hence, for a relation \( R \) on \( A \) to be “not symmetric,” there must be some ordered pair \( (w, z) \) in \( R \) for which \( (z, w) \notin R \). Certainly, if such an ordered pair \( (w, z) \) exists, then \( w \neq z \). The relation \( R_1 \) is not symmetric since \( (c, a) \in R_1 \) but \( (a, c) \notin R_1 \). Notice that
(a, b) ∈ R₁ and (b, a) ∈ R₁ as well. However, this does not mean that R₁ is symmetric. Recall that the definition of a symmetric relation R on a set A says that whenever x R y, then y R x for all x, y ∈ A.

The relation R₃ is symmetric, however, since both (a, c) and (c, a) belong to R₃. None of the ordered pairs (a, a), (b, b), (c, c) in R₃ are relevant as to whether R₃ is symmetric. None of the relations R₂, R₄, R₅, R₆ are symmetric.

Finally, we describe the third important property that a relation defined on a single set may possess.

A relation R defined on a set A is called transitive if whenever x R y and y R z, then x R z, for all x, y, z ∈ A.

Notice that in this definition, it is not required that x, y, and z be distinct. Hence, for a relation R on A to be “not transitive,” there must exist two ordered pairs (u, v) and (v, w) in R such that (u, v) ∉ R. If this should occur, then necessarily u ≠ v and v ≠ w (although perhaps u = w). For example, the relation R₂ is not transitive since (a, b), (b, c) ∈ R₂ but (a, c) ∉ R₂. Actually, R₁ is not transitive either because (a, b), (b, a) ∈ R₁ but (a, a) ∉ R₁. The example (counterexample) that shows that R₁ is not transitive illustrates the fact that showing a relation is not transitive may not be easy. All of the relations R₃, R₄, R₅, R₆ are transitive. It is not always easy to convince oneself that a relation is transitive either. Let’s give a careful argument as to why the relations R₃ and R₆ are transitive.

For R₃ to be transitive, it is required that (x, z) belongs to R₃ whenever (x, y) and (y, z) belong to R₃ for all x, y, z ∈ A. To verify that the transitive property holds in R₃, we must consider all possible pairs of ordered pairs of the type (x, y) and (y, z). We have two choices for (x, y) in R₃, namely, (a, a) and (a, b), that is, x = a and y = a, or x = a and y = b. If (x, y) = (a, a), then y = a and so either (y, z) = (a, a) or (y, z) = (a, b). In the first case, we have (a, a) ∈ R₃ and (a, a) ∈ R₃, and (x, z) = (a, b) belongs to R₃. In the second case, (a, a) ∈ R₃ and (a, b) ∈ R₃, and (x, z) = (a, b) belongs to R₃. This example suggests (correctly!) that if (x, y) and (y, z) belong to some relation R and x = y, then certainly (x, z) ∈ R. The same could be said if y = z. Thus, when checking transitivity, we need only consider ordered pairs (x, y) and (y, z) for which x ≠ y and y ≠ z. Suppose next that (x, y) = (a, b), so that y = b. Here there is no ordered pair of the type (y, z); that is, there is no ordered pair of R₃ whose first coordinate is b. Thus, there is nothing to check when (x, y) = (a, b). For R₅, there are only two possibilities for two ordered pairs of the type (x, y), (y, z) in each case, (x, z) ∈ R₃. Thus, R₃ is transitive.

Let’s turn to R₆ now. The relation R₆ does not contain two ordered pairs of the type (x, y), (y, z) since if (x, y) = (a, b), no ordered pair has b as its first coordinate; while if (x, y) = (a, c), no ordered pair has c as its first coordinate. Consequently, the hypothesis of the transitive property is false and the implication “If (x, y) ∈ R₆ and (y, z) ∈ R₆, then (x, z) ∈ R₆.” is satisfied vacuously. Hence, R₆ is transitive. Another way to convince yourself that R₆ is transitive is to think of what must happen if R₆ is not transitive; namely, there must be two ordered pairs (x, y), (y, z) in R₆ such that (x, z) ∉ R₆. But there are no such ordered pairs (x, y) and (y, z)!

In the preceding discussions, we have made use of an important point when testing a relation for transitivity. It bears repeating here.

When we are attempting to determine whether a relation R is transitive and, consequently, checking all pairs of the type (x, y) and (y, z), we need not consider the situation where x = y or y = z.
228 Chapter 9 Equivalence Relations

In this case, the ordered pair \((x, z)\) will always be present in \(R\). If a relation \(R\) is not transitive, then there must exist ordered pairs \((x, y)\) and \((y, z)\) in \(R\), where \(x \neq y\) and \(y \neq z\), such that \((x, z)\) is not in \(R\). That is, \((x, y)\) and \((y, z)\) constitute a counterexample to the implication “If \((x, y) \in R\) and \((y, z) \in R\), then \((x, z) \in R\),” which is a requirement of \(R\) being transitive.

Let’s consider two additional relations \(R_7\) and \(R_8\) defined on the set \(S = \{a, b, c\}\):

\[
R_7 = \{(a, a), (a, b), (b, a), (b, b), (b, c), (c, c)\}
\]

\[
R_8 = \{(a, a), (a, c), (c, a)\}.
\]

Since \((a, a), (b, b), (c, c) \in R_7\), it follows that \(R_7\) is reflexive. Because \((b, c) \in R_7\) but \((c, b) \notin R_7\), the relation \(R_7\) is not symmetric. Since \((a, b), (b, c) \in R_7\) but \((a, c) \notin R_7\), the relation \(R_7\) is not transitive. Since \((b, b) \notin R_8\), for example, the relation \(R_8\) is not reflexive. Because \((a, c), (c, a) \in R_8\), the relation \(R_8\) is symmetric. Since \((c, a), (a, c) \in R_8\) but \((c, c) \notin R_8\), the relation \(R_8\) is not transitive.

Let’s summarize then what we have said about the properties of being reflexive, symmetric and transitive that the relations \(R_1, R_2, \ldots, R_8\) defined on \(S = \{a, b, c\}\) possess.

We already mentioned that relations occur frequently in mathematics. Let \(R\) be the relation defined on the set \(\mathbb{Z}\) of integers by \(a R b\) if \(a \leq b\); that is, \(R\) is the relation \(\leq\).

Since \(x \leq x\) for every integer \(x\), it follows that \(x R x\) for every \(x \in \mathbb{Z}\); that is, \(R\) is reflexive. Certainly, \(2 R 3\) since \(2 \leq 3\). However, \(3 > 2\); so \(3 R 2\). Therefore, \(R\) is not symmetric. On the other hand, it is a well-known property of integers that if \(a \leq b\) and \(b \leq c\), then \(a \leq c\). Therefore, if \(a R b\) and \(b R c\), then \(a R c\). So, \(R\) is transitive.

Another relation \(R\) we could consider is defined by \(a R b\) if \(a \neq b\). However, then \(1 R 1\) since \(1 = 1\). Consequently, this relation is not reflexive. If \(a\) and \(b\) are integers such that \(a \neq b\), then we also have \(b \neq a\). So, if \(a R b\), then \(b R a\). This says that this relation is symmetric. Notice that \(2 \neq 3\) and \(3 \neq 2\) but \(2 = 2\). That is, \(2 R 3\) and \(3 R 2\) but \(2 R 2\). Therefore, \(R\) is not transitive.

The distance between two real numbers \(a\) and \(b\) is \(|a - b|\). So the distance between \(2\) and \(4.5\) is \(|2 - 4.5| = |-2.5| = 2.5\). Thus, if the real numbers (points) \(a\) and \(b\) are plotted on the real number line (x-axis), then the length of this segment is the distance between them. This is illustrated in Figure 9.1 for the real numbers \(a = 3\) and \(b = -2\), where the distance between them is thus \(|a - b| = |3 - (-2)| = 5 = |(-2) - 3| = |b - a|\).

![Figure 9.1](image-url) The distance between 3 and -2
Define a relation \( R \) on the set \( \mathbb{R} \) of real numbers by \( a \, R \, b \) if \( |a - b| \leq 1 \), that is, \( a \) is related to \( b \) if the distance between \( a \) and \( b \) is at most 1. Certainly, the distance from a real number to itself is 0, that is, \( |a - a| = 0 \leq 1 \) for every \( x \in \mathbb{R} \). So, \( a \, R \, a \) and \( R \) is reflexive. If the distance between two real numbers \( a \) and \( b \) is at most 1, then the distance between \( b \) and \( a \) is at most 1. In symbols, if \( |a - b| \leq 1 \), then \( |b - a| = |a - b| \leq 1 \); that is, if \( a \, R \, b \), then \( b \, R \, a \). Therefore, \( R \) is symmetric. Now to the transitive property. If \( a \, R \, b \) and \( b \, R \, c \), is \( a \, R \, c \)? That is, if the distance between \( a \) and \( b \) is at most 1 and the distance between \( b \) and \( c \) is at most 1, does it follow that the distance between \( a \) and \( c \) is at most 1? The answer is no. For example, \( 3 \, R \, 2 \) and \( 2 \, R \, 1 \) since \( |3 - 2| \leq 1 \) and \( |2 - 1| \leq 1 \). However, \( |3 - 1| = 2 \). So, \( 3 \, R \, 1 \) and \( R \) is not transitive.

### SECTION 9.2 EXERCISES

9.11. Let \( A = \{a, b, c, d\} \) and let \( R = \{(a, a), (a, b), (a, c), (a, d), (b, b), (b, c), (b, d), (c, c), (c, d), (d, d)\} \) be a relation on \( A \). Which of the properties reflexive, symmetric and transitive does the relation \( R \) possess? If \( R \) does not possess one of these properties, explain why.

9.12. Let \( S = \{a, b, c\} \). Then \( R = \{(a, a), (a, b), (a, c)\} \) is a relation on \( S \). Which of the properties reflexive, symmetric and transitive does the relation \( R \) possess? Justify your answers.

9.13. Let \( S = \{a, b, c\} \). Then \( R = \{(a, b)\} \) is a relation on \( S \). Which of the properties reflexive, symmetric and transitive does the relation \( R \) possess?

9.14. Let \( A = \{a, b, c, d\} \). Give an example (with justification) of a relation \( R \) on \( A \) that has none of the following properties: reflexive, symmetric, transitive.

9.15. A relation \( R \) is defined on \( \mathbb{Z} \) by \( a \, R \, b \) if \( |a - b| \leq 2 \). Which of the properties reflexive, symmetric and transitive does the relation \( R \) possess? If \( R \) does not possess one of these properties, explain why.

9.16. Let \( A = \{a, b, c, d\} \). How many relations defined on \( A \) are reflexive, symmetric and transitive and contain the ordered pairs \( (a, b), (b, c), (c, d) \)?

9.17. Let \( R = \emptyset \) be the empty relation on a nonempty set \( A \). Which of the properties reflexive, symmetric and transitive does \( R \) possess?

9.18. Let \( A = \{1, 2, 3, 4\} \). Give an example of a relation on \( A \) that is:
   (a) reflexive and symmetric but not transitive.
   (b) reflexive and transitive but not symmetric.
   (c) symmetric and transitive but not reflexive.
   (d) reflexive but neither symmetric nor transitive.
   (e) symmetric but neither reflexive nor transitive.
   (f) transitive but neither reflexive nor symmetric.

9.19. A relation \( R \) is defined on \( \mathbb{Z} \) by \( x \, R \, y \) if \( x \cdot y \geq 0 \). Prove or disprove the following: (a) \( R \) is reflexive, (b) \( R \) is symmetric, (c) \( R \) is transitive.

9.20. Determine the maximum number of elements in a relation \( R \) on a 3-element set such that \( R \) has none of the properties reflexive, symmetric and transitive.

9.21. Prove or disprove: If there exists a relation \( R_1 \) on the set \( \{a_1, a_2\} \) that is not reflexive, not symmetric and not transitive, then there exists a relation \( R_2 \) on the set \( \{b_1, b_2, b_3\} \) that is not reflexive, not symmetric and not transitive.
Chapter 9  Equivalence Relations

9.22. Let $S$ be the set of all polynomials of degree at most 3. An element $s$ of $S$ can then be expressed as $s = ax^3 + bx^2 + cx + d$, where $a, b, c, d \in \mathbb{R}$. A relation $R$ is defined on $S$ by $p R q$ if $p$ and $q$ have a root in common. (For example, $p = (x - 1)^2$ and $q = x^2 - 1$ have the root 1 in common so that $p R q$.) Determine which of the properties reflexive, symmetric and transitive are possessed by $R$.

9.23. A relation $R$ is defined on $\mathbb{N}$ by $a R b$ if either $a \mid b$ or $b \mid a$. Determine which of the properties reflexive, symmetric and transitive are possessed by $R$.

9.3 EQUIVALENCE RELATIONS

The most familiar relation in mathematics is probably the equals relation. Let $R$ be that relation on the set of integers; that is, $R$ is the relation defined on $\mathbb{Z}$ by $a R b$ if $a = b$. Since $a = a$ for every integer $a$, it follows that $a R a$. If $a = b$, then $b = a$. Hence, if $a R b$, then $b R a$. Also, if $a = b$ and $b = c$, then $a = c$. So if $a R b$ and $b R c$, then $a R c$. These observations tell us that the equals relation on the set of integers possesses all three of the properties reflexive, symmetric and transitive. This suggests the question of what other relations (on the set $\mathbb{Z}$ or indeed on any set) have these same three properties possessed by the equals relation. These are the relations that will be our primary focus in this chapter.

A relation $R$ defined on a set $A$ is called an equivalence relation if $R$ is reflexive, symmetric and transitive. Of course then, the equals relation $R$ defined on $\mathbb{Z}$ by $a R b$ if $a = b$ is an equivalence relation on $\mathbb{Z}$. For another example, consider the set $A = \{1, 2, 3, 4, 5, 6\}$ and let $R$ be the relation defined on $A$ that consists of the following ordered pairs:

$$R = \{(1, 1), (2, 2), (3, 3), (4, 4), (5, 5), (6, 6), (1, 3), (1, 6), (6, 1), (6, 3), (3, 1), (3, 6), (2, 4), (4, 2)\}. \quad (9.2)$$

Since this relation has all three of the properties reflexive, symmetric and transitive, it is an equivalence relation.

Suppose that $R$ is an equivalence relation on some set $A$. If $a \in A$, then $a$ is related to $a$ since $R$ is reflexive. Quite possibly, other elements of $A$ are related to $a$ as well. The set consisting of all those elements that are related to a given element of $A$ will turn out to be important and, for this reason, these sets are given special names. For an equivalence relation $R$ defined on a set $A$ and for an element $a \in A$, the set

$$[a] = \{x \in A : x R a\},$$

consisting of all elements in $A$ that are related to $a$, is called an equivalence class. In fact, $[a]$ is the equivalence class containing $a$ since $a \in [a]$ (because $R$ is reflexive). Loosely speaking then, $[a]$ consists of the “relatives” of $a$. For the equivalence relation $R$ defined in (9.2), the resulting equivalence classes are

$$[1] = \{1, 3, 6\}, \quad [2] = \{2, 4\}, \quad [3] = \{1, 3, 6\},$$

$$[4] = \{2, 4\}, \quad [5] = \{5\}, \quad [6] = \{1, 3, 6\}. \quad (9.3)$$

Let’s return to the equals relation $R$ defined on $\mathbb{Z}$ by $a R b$ if $a = b$ to determine the equivalence classes in this case. For $a \in \mathbb{Z}$,

$$[a] = \{x \in \mathbb{Z} : x \equiv a\} = \{x \in \mathbb{Z} : x = a\} = \{a\};$$

that is, every integer is in an equivalence class by itself.

We now consider a similar relation on $\mathbb{Z}$.

**Example 9.1** A relation $R$ is defined on $\mathbb{Z}$ by $x R y$ if $|x| = |y|$. This relation is also an equivalence relation. In this case, for $a \in \mathbb{Z}$, the equivalence class $[a]$ consists of the two integers $a$ and $-a$, unless $a = 0$, in which case $[0] = \{0\}$. ♦

We now consider two examples from geometry.

**Example 9.2** A relation $R$ is defined on the set $L$ of straight lines in the plane by $\ell_1 R \ell_2$ if either $\ell_1 = \ell_2$ (the lines coincide) or $\ell_1$ is parallel to $\ell_2$. Since every line coincides with itself, $R$ is reflexive. If a line $\ell_1$ is parallel to a line $\ell_2$ (or they coincide), then $\ell_2$ is parallel to $\ell_1$ (or they coincide). Thus, $R$ is symmetric. Finally, if $\ell_1$ is parallel to $\ell_2$ and $\ell_2$ is parallel to $\ell_3$ (including the possibility that such pairs of lines may coincide), then either $\ell_1$ is parallel to $\ell_3$ or they coincide. Indeed, it may very well occur that $\ell_1$ and $\ell_2$ are distinct parallel lines, as are $\ell_2$ and $\ell_3$ but $\ell_1$ and $\ell_3$ coincide. In any case, though, this relation is transitive. Therefore, $R$ is an equivalence relation. Hence, for $\ell \in L$, the equivalence class

$$[\ell] = \{x \in L : x \ell \} = \{x \in L : x = \ell \text{ or } x \text{ is parallel to } \ell\}$$

consists of $\ell$ and all lines in the plane parallel to $\ell$. ♦

**Example 9.3** Let $T$ be the set of all triangles in a plane. We now describe two relations $R_1$ and $R_2$ defined on $T$. The relation $R_1$ is defined by $T R_1 T'$ if $T$ is congruent to $T'$ and the relation $R_2$ is defined by $T R_2 T'$ if $T$ is similar to $T'$. Then both $R_1$ and $R_2$ are equivalence relations. For a triangle $T$ and the relation $R_1$, $[T]$ is the set of triangles in $T$ that are congruent to $T$; while for $R_2$, $[T]$ is the set of triangles in $T$ that are similar to $T$. ♦

We now consider examples of relations defined on $\mathbb{Z}$ that may require some additional thought.

**Result 9.4** The relation $R$ defined on $\mathbb{Z}$ by $x R y$ if $x + 3y$ is even is an equivalence relation.

Before proving this result, let’s be certain that we understand this relation. First, notice that $5 R 7$ since $5 + 3 \cdot 7 = 26$ is even. However, $8 \not R 9$ since $8 + 3 \cdot 9 = 35$ is not even. On the other hand, $4 \not R 4$ because $4 + 3 \cdot 4 = 16$ is even.

**Proof of Result 9.4** First, we show that $R$ is reflexive. Let $a \in \mathbb{Z}$. Then $a + 3a = 4a = 2(2a)$ is even since $2a \in \mathbb{Z}$. Therefore, $a R a$ and $R$ is reflexive.

Next, we show that $R$ is symmetric. Assume that $a R b$. Thus, $a + 3b$ is even. Hence, $a + 3b = 2k$ for some integer $k$. So, $a = 2k - 3b$. Therefore,

$$b + 3a = b + 3(2k - 3b) = b + 6k - 9b = 6k - 8b = 2(3k - 4b).$$

Since $3k - 4b$ is an integer, $b + 3a$ is even. Therefore, $b R a$ and $R$ is symmetric.
Finally, we show that \( R \) is transitive. Assume that \( a R b \) and \( b R c \). Hence, \( a + 3b \) and \( b + 3c \) are even; so \( a + 3b = 2k \) and \( b + 3c = 2\ell \) for some integers \( k \) and \( \ell \). Adding these two equations, we obtain \( (a + 3b) + (b + 3c) = 2k + 2\ell \). So \( a + 4b + 3c = 2k + 2\ell \) and \( a + 3c = 2k + 2\ell - 4b = 2(k + \ell - 2b) \). Since \( k + \ell - 2b \) is an integer, \( a + 3c \) is even. Hence, \( a R c \) and so \( R \) is transitive. Therefore, \( R \) is an equivalence relation. \( \blacksquare \)

**Proof Analysis**

A few remarks concerning the preceding proof are in order. Recall that a relation \( \sim \) defined on a set \( A \) is reflexive if \( x \sim x \) for every \( x \in A \). The reflexive property may also be reworded to read: For every \( x \in A \), \( x R x \) or: If \( x \in A \), then \( x R x \). Hence, when we proved that \( R \) is reflexive in Result 9.4, we began by assuming that \( a \) was an arbitrary element of \( \mathbb{Z} \). (We’re giving a direct proof.) We were then required to show that \( a \sim 3a \) is even, which we did. It would be incorrect, however, to assume that \( a \sim 3a \) is even or that \( a R a \). This, in fact, is what we want to prove. ♦

Since the relation defined in Result 9.4 is an equivalence relation, there are equivalence classes, namely an equivalence class \([a]\) for each \( a \in \mathbb{Z} \). Let’s start with 0, say. The equivalence class \([0]\) is the set of all integers related to 0. In symbols, this equivalence class is

\[
[0] = \{x \in \mathbb{Z} : x R 0\} = \{x \in \mathbb{Z} : x + 3 \cdot 0 \text{ is even}\} \\
= \{x \in \mathbb{Z} : x \text{ is even}\} = \{0, \pm 2, \pm 4, \ldots\};
\]

that is, \([0]\) is the set of even integers. It shouldn’t be difficult to see that if \( a \) is an even integer, say \( a = 2k \), where \( k \in \mathbb{Z} \), then

\[
[a] = \{x \in \mathbb{Z} : x R a\} = \{x \in \mathbb{Z} : x + 3a \text{ is even}\} \\
= \{x \in \mathbb{Z} : x + 3(2k) \text{ is even}\} = \{x \in \mathbb{Z} : x + 6k \text{ is even}\}
\]

is also the set of even integers. On the other hand, the equivalence class consisting of those integers related to 1 is

\[
[1] = \{x \in \mathbb{Z} : x R 1\} = \{x \in \mathbb{Z} : x + 3 \cdot 1 \text{ is even}\} \\
= \{x \in \mathbb{Z} : x + 3 \text{ is even}\} = \{\pm 1, \pm 3, \pm 5, \ldots\},
\]

which is the set of odd integers. In fact, if \( a \) is an odd integer, then \( a = 2\ell + 1 \) for some integer \( \ell \) and

\[
[a] = \{x \in \mathbb{Z} : x + 3a \text{ is even}\} = \{x \in \mathbb{Z} : x + 3(2\ell + 1) \text{ is even}\} \\
= \{x \in \mathbb{Z} : x + 6\ell + 3 \text{ is even}\}
\]

is the set of odd integers. Therefore, if \( a \) and \( b \) are even, then \([a] = [b]\) is the set of even integers; while if \( a \) and \( b \) are odd, then \([a] = [b]\) is the set of odd integers. Hence, there are only two distinct equivalence classes, namely \([0]\) and \([1]\), the sets of even and odd integers, respectively. We will soon see that there is a good reason for this observation.

We consider some additional examples.

**Result 9.5**

The relation \( R \) defined on \( \mathbb{Z} \) by \( a R b \) if \( 3 \mid (2a + 7b) \) is an equivalence relation.

**Proof**

First, we show that \( R \) is reflexive. Let \( a \in \mathbb{Z} \). Observe that \( 2a + 7a = 9a = 3(3a) \). Since \( 3a \in \mathbb{Z} \), it follows that \( 3 \mid (2a + 7a) \). Thus, \( a R a \) and \( R \) is reflexive.
Next, we show that $R$ is symmetric. Assume that $aRb$. Thus, $3 \mid (2a + 7b)$. Hence, $2a + 7b = 3x$ for some integer $x$. We show that $bRa$, that is, $3 \mid (2b + 7a)$. Since $2a + 7b = 3x$, it follows that $4a = 6x - 14b$. Hence,

$$2b + 7a = 2b + 3a + 4a = 2b + 3a + (6x - 14b) = 3a + 6x - 12b = 3(a + 2x - 4b).$$

Since $a + 2x - 4b$ is an integer, $3 \mid (2b + 7a)$. Therefore, $bRa$ and $R$ is symmetric.

Finally, we show that $R$ is transitive. Assume that $aRb$ and $bRc$. Hence, $2a + 7b = 3x$ and $2b + 7c = 3y$ for some integers $x$ and $y$. Adding these two equations, we obtain

$$(2a + 7b) + (2b + 7c) = 3x + 3y.$$

So, $2a + 7c = 3x + 3y - 9b = 3(x + y - 3b)$. Since $x + y - 3b$ is an integer, $3 \mid (2b + 7c)$. Hence, $aRc$ and so $R$ is transitive.

Therefore, $R$ is an equivalence relation.

Let’s see what the equivalence classes look like for the equivalence relation defined in Result 9.5. We begin with the integer 0. Here,

$$[0] = \{x \in \mathbb{Z} : x R 0\} = \{x \in \mathbb{Z} : 3 \mid (2x + 7 \cdot 0)\} = \{x \in \mathbb{Z} : 3 \mid 2x = \{x \in \mathbb{Z} : 3 \mid x\} = \{0, \pm 3, \pm 6, \ldots\}.$$ 

For the integer 1,

$$[1] = \{x \in \mathbb{Z} : x R 1\} = \{x \in \mathbb{Z} : 3 \mid (2x + 7 \cdot 1)\} = \{x \in \mathbb{Z} : 3 \mid (2x + 7)\} = \{1, -2, 4, -5, 7, -8, 10, \ldots\}.$$ 

In addition,

$$[2] = \{x \in \mathbb{Z} : x R 2\} = \{x \in \mathbb{Z} : 3 \mid (2x + 7 \cdot 2)\} = \{x \in \mathbb{Z} : 3 \mid (2x + 14)\} = \{2, -1, 5, -4, 8, -7, 11, \ldots\}.$$ 

It turns out that these are the only distinct equivalence classes.

**Result 9.6** Let $S = \{k\sqrt{2} : k \in \mathbb{Z}\}$. The relation $R$ defined on $S$ by $x R y$ if $xy \in \mathbb{Z}$ is an equivalence relation.

**Proof** First, observe that if $x$ and $y$ are any two elements of $S$, then $x = k\sqrt{2}$ and $y = \ell\sqrt{2}$ for integers $k$ and $\ell$. Furthermore, $xy = (k\sqrt{2})(\ell\sqrt{2}) = 2k\ell$. Since $2k\ell \in \mathbb{Z}$, it follows that $x R y$. Hence, $R$ is reflexive, symmetric and transitive and so $R$ is an equivalence relation.

For the equivalence relation defined in Result 9.6 and an arbitrary element $a \in S$, we have $x R a$ for each element $x \in R$. Thus, $[a] = S$ and so there is a single equivalence class in this case.

**Result 9.7** Let $A = \mathbb{Z}$ and $B = \mathbb{Z} - \{0\}$. The relation $R$ defined on $A \times B$ by $(a, b) R (c, d)$ if $ad = bc$ is an equivalence relation.
234 Chapter 9 Equivalence Relations

Proof Let \((a, b) \in A \times B\). Since \(ab = ba\), it follows that \((a, b) R (a, b)\) and so \(R\) is reflexive.

Next, we show that \(R\) is symmetric. Let \((a, b), (c, d) \in A \times B\) such that \((a, b) R (c, d)\). Then \(ad = bc\). Consequently, \(cb = da\) and so \((c, d) R (a, b)\). Therefore, \(R\) is symmetric.

Finally, we show that \(R\) is transitive. Let \((a, b), (c, d), (e, f) \in A \times B\) such that \((a, b) R (c, d)\) and \((c, d) R (e, f)\). Thus, \(ad = bc\) and \(cf = de\). We show that \((a, b) R (e, f)\).

Observe that

\[
adf = (ad)f = (bc)f = b(cf) = b(de) = bde
\]

and so \(adf = bde\). Since \(d \in B\), it follows that \(d \neq 0\). Dividing both sides of \(adf = bde\) by \(d\), we have \(af = be\). Thus, \((a, b) R (e, f)\) and so \(R\) is transitive.

Therefore, \(R\) is an equivalence relation.

The primary interest in the equivalence relation defined in Result 9.7 lies in the equivalence classes. For example, consider the equivalence class \([1, 2]\), which consists of all ordered pairs \((x, y) \in A \times B\) that are related to \((1, 2)\). By definition, \((x, y) R (1, 2)\) if \(y = 2x\). That is, \([1, 2]\) consists of all ordered pairs of integers, different from \((0, 0)\), whose second coordinate is twice the first coordinate. We can therefore think of \((1, 2)\) as representing the rational number \(\frac{1}{2}\) and \([1, 2]\) consists of all of those representations of \(\frac{1}{2}\), such as \(\frac{2}{4}, \frac{3}{6}, \frac{-5}{10}\), etc. In general, for \(a, b \in \mathbb{Z}\) with \(b \neq 0\), the ordered pair \((a, b)\) represents the rational number \(\frac{a}{b}\) and \([a, b]\) consists of all rational numbers equal to \(\frac{a}{b}\) such as \(\frac{2a}{2b}, \frac{3a}{3b}, \frac{-5a}{-3b}\), etc.

SECTION 9.3 EXERCISES

9.24. Let \(R\) be an equivalence relation on \(A = \{a, b, c, d, e, f, g\}\) such that \(a R c, c R d, d R g\) and \(b R f\). If there are three distinct equivalence classes resulting from \(R\), then determine these equivalence classes and determine all elements of \(R\).

9.25. Let \(A = \{1, 2, 3, 4, 5, 6\}\). The relation

\[
R = \{(1, 1), (1, 5), (2, 2), (2, 3), (2, 6), (3, 2), (3, 3), (3, 6), (4, 4), (5, 1), (5, 5), (6, 2), (6, 3), (6, 6)\}
\]

is an equivalence relation on \(A\). Determine the distinct equivalence classes.

9.26. Let \(A = \{1, 2, 3, 4, 5, 6\}\). The distinct equivalence classes resulting from an equivalence relation \(R\) on \(A\) are \(\{1, 4, 5\}, \{2, 6\}\) and \(\{3\}\). What is \(R\)?

9.27. Let \(R\) be a relation defined on \(\mathbb{Z}\) by \(a R b\) if \(a^3 = b^3\). Show that \(R\) is an equivalence relation on \(\mathbb{Z}\) and determine the distinct equivalence classes.

9.28. (a) Let \(R\) be the relation defined on \(\mathbb{Z}\) by \(a R b\) if \(a + b\) is even. Show that \(R\) is an equivalence relation and determine the distinct equivalence classes.

(b) Suppose that “even” is replaced by “odd” in (a). Which of the properties reflexive, symmetric and transitive does \(R\) possess?

9.29. Let \(R\) be an equivalence relation defined on a set \(A\) containing the elements \(a, b, c\) and \(d\). Prove that if \(a R b, c R d\) and \(a R d\), then \(b R c\).
9.30. Let \( H = \{2^m : m \in \mathbb{Z}\} \). A relation \( R \) is defined on the set \( \mathbb{Q}^+ \) of positive rational numbers by \( a \mathcal{R} b \) if \( a/b \in H \).

(a) Show that \( R \) is an equivalence relation.

(b) Describe the elements in the equivalence class \([3]\).

9.31. A relation \( R \) on a nonempty set \( A \) is defined to be circular if whenever \( x \mathcal{R} y \) and \( y \mathcal{R} z \), then \( z \mathcal{R} x \) for all \( x, y, z \in A \). Prove that a relation \( R \) on \( A \) is an equivalence relation if and only if \( R \) is circular and reflexive.

9.32. A relation \( R \) is defined on the set \( A = \{a + b\sqrt{2} : a, b \in \mathbb{Q}, a + b\sqrt{2} \neq 0\} \) by \( x \mathcal{R} y \) if \( x/y \in \mathbb{Q} \). Show that \( R \) is an equivalence relation and determine the distinct equivalence classes.

9.33. Let \( H = \{4k : k \in \mathbb{Z}\} \). A relation \( R \) is defined on \( \mathbb{Z} \) by \( a \mathcal{R} b \) if \( a - b \in H \).

(a) Show that \( R \) is an equivalence relation.

(b) Determine the distinct equivalence classes.

9.34. Let \( H \) be a nonempty subset of \( \mathbb{Z} \). Suppose that the relation \( R \) defined on \( \mathbb{Z} \) by \( a \mathcal{R} b \) if \( a - b \in H \) is an equivalence relation. Verify the following

(a) \( 0 \in H \).

(b) If \( a \in H \), then \(-a \in H \).

(c) If \( a, b \in H \), then \( a + b \in H \).

9.35. Prove or disprove: There exist equivalence relations \( R_1 \) and \( R_2 \) on the set \( S = \{a, b, c\} \) such that \( R_1 \nsubseteq R_2, R_2 \nsubseteq R_1 \) and \( R_1 \cup R_2 = S \times S \).

### 9.4 Properties of Equivalence Classes

You may have noticed that in the preceding examples of equivalence relations, we have seen several situations where two equivalence classes are equal. It is possible to determine exactly when this happens.

**Theorem 9.8** Let \( R \) be an equivalence relation on a nonempty set \( A \) and let \( a \) and \( b \) be elements of \( A \). Then \([a] = [b]\) if and only if \( a \mathcal{R} b \).

**Proof** Assume that \( a \mathcal{R} b \). We show that the sets \([a]\) and \([b]\) are equal by verifying that \([a] \subseteq [b]\) and \([b] \subseteq [a]\). First, we show that \([a] \subseteq [b]\). Let \( x \in [a] \). Then \( x \mathcal{R} a \). Since \( a \mathcal{R} b \) and \( R \) is transitive, \( x \mathcal{R} b \). Therefore, \( x \in [b] \) and so \([a] \subseteq [b]\). Next, let \( y \in [b] \). Thus, \( y \mathcal{R} b \). Since \( a \mathcal{R} b \) and \( R \) is symmetric, \( b \mathcal{R} a \). Again, by the transitivity of \( R \), we have \( y \mathcal{R} a \). Therefore, \( y \in [a] \) and so \([b] \subseteq [a]\). Hence, \([a] = [b]\).

For the converse, assume that \([a] = [b]\). Because \( R \) is reflexive, \( a \in [a] \). But, since \([a] = [b]\), it follows that \( a \in [b] \). Consequently, \( a \mathcal{R} b \).

**Corollary 9.9** Let \( R \) be an equivalence relation on a nonempty set \( A \) and let \( a \) and \( b \) be elements of \( A \). If \([a] \cap [b] \neq \emptyset\), then \([a] = [b]\).

**Proof** Since \([a] \cap [b] \neq \emptyset\), there is an element \( c \in A \) such that \( c \in [a] \cap [b] \). Since \( c \in [a] \), it follows that \( c \mathcal{R} a \) and since \( c \in [b] \), we have \( c \mathcal{R} b \). Because \( R \) is symmetric, \( a \mathcal{R} c \) and because \( R \) is transitive, \( a \mathcal{R} b \). By Theorem 9.8, \([a] = [b]\).

Theorem 9.8 and Corollary 9.9 provide another corollary.
236 Chapter 9 Equivalence Relations

Corollary 9.10 Let $R$ be an equivalence relation on a nonempty set $A$ and let $a$ and $b$ be elements of $A$. Then $a R b$ if and only if $[a] \cap [b] = \emptyset$.

Proof Suppose first that $a R b$. By Theorem 9.8 then, $[a] \neq [b]$. Hence, $[a] \cap [b] = \emptyset$ by Corollary 9.9. For the converse, suppose that $[a] \cap [b] = \emptyset$. Thus, $[a] \neq [b]$ and so $a R b$ by Theorem 9.8.

Let’s return once more to the equivalence relation defined in (9.2) on the set $A = \{1, 2, 3, 4, 5, 6\}$ and the equivalence classes given in (9.3). We observed earlier that $[1] = [3] = [6]$. Since every two of the integers $1, 3, 6$ are related to each other (according to the definition of $R$), Theorem 9.8 tells us that the equality of $[1], [3]$ and $[6]$ is expected. The same can be said of $[2]$ and $[4]$. However, since $(5, 6) \notin R$, for example, we know not only that $[5] \neq [6]$ but that $[5]$ and $[6]$ are disjoint. Therefore, as we also observed earlier, there are only three distinct equivalence classes, namely,

$$[1] = [3] = [6] = \{1, 3, 6\}, \quad [2] = [4] = \{2, 4\}, \quad [5] = \{5\}. \quad (9.4)$$

Now, you might have noticed one other thing. Every element of $A$ belongs to exactly one equivalence class. This observation might remind you of a concept we discussed earlier.

Recall that a partition $P$ of a nonempty set $S$ is a collection of nonempty subsets of $S$ with the property that every element of $S$ belongs to exactly one of these subsets; that is, $P$ is a collection of pairwise disjoint, nonempty subsets of $S$ whose union is $S$. Hence, the set of the distinct equivalence classes in (9.4) is a partition of the set $A = \{1, 2, 3, 4, 5, 6\}$. We now show that this too is expected.

Theorem 9.11 Let $R$ be an equivalence relation defined on a nonempty set $A$. Then the set of distinct equivalence classes resulting from $R$ is a partition of $A$.

Proof Certainly, each equivalence class $[a]$ is nonempty since $a \in [a]$ and so each element of $A$ belongs to at least one equivalence class. We show that every element of $A$ belongs to exactly one equivalence class. If some element $x$ of $A$ belongs to two equivalence classes, say $[a]$ and $[b]$, then $[a] = [b]$ by Corollary 9.9. Hence, every element of $A$ belongs to a unique equivalence class.

According to Theorem 9.11 then, whenever we have an equivalence relation $R$ defined on a nonempty set $A$, a partition of $A$ into the associated equivalence classes of $R$ results. Perhaps unexpectedly, the converse is also true. That is, if we are given a partition of $A$, then there is an equivalence relation that can be defined on $A$ whose resulting equivalence classes are precisely the subsets in the given partition. For example, consider the partition

$$P = \{\{1, 3, 4\}, \{2, 7\}, \{5, 6\}\}$$

of the set $A = \{1, 2, 3, 4, 5, 6, 7\}$. (Necessarily then, every element of $A$ belongs to exactly one subset in $P$.) Then

$$R = \{(1, 1), (1, 3), (1, 4), (2, 2), (2, 7), (3, 1), (3, 3), (3, 4), (4, 1), (4, 3), (4, 4), (5, 5), (5, 6), (6, 6), (7, 2), (7, 7)\}$$
is an equivalence relation on $A$, whose distinct equivalence classes are
\[ [1] = \{1, 3, 4\}, \quad [2] = \{2, 7\} \quad \text{and} \quad [5] = \{5, 6\}, \]
and so $P = \{[1], [2], [5]\}$. We now establish this result in general. That is, if we have a nonempty set $A$ and a partition $P$ of $A$, then it is possible to create an equivalence relation $R$ on $A$ such that the distinct equivalence classes of $R$ are precisely the subsets in $P$. Since we are trying to verify this in general (and not for a specific example), we need to describe the subsets in $P$ with the aid of an index set. Since we will want every subset in $P$ to be an equivalence class, we will need every two elements in the same subset to be related. On the other hand, since we will want two different subsets in $P$ to be different equivalence classes, we will need elements in distinct subsets not to be related.

**Theorem 9.12** Let $P = \{A_\alpha : \alpha \in I\}$ be a partition of a nonempty set $A$. Then there exists an equivalence relation $R$ on $A$ such that $P$ is the set of equivalence classes determined by $R$, that is, $P = \{[a] : a \in A\}$.

**Proof** Define a relation $R$ on $A$ by $x \sim y$ if $x$ and $y$ belong to the same subset in $P$; that is, $x \sim y$ if $x, y \in A_\beta$, for some $\alpha \in I$. We now show that $R$ is an equivalence relation. Let $a \in A$. Since $P$ is a partition of $A$, it follows that $a \in A_\beta$ for some $\beta \in I$. Trivially, $a$ and $a$ belong to $A_\beta$; so $aRa$ and $R$ is reflexive.

Next, let $a, b \in A$ and assume that $aRa$. Then $a$ and $b$ belong to $A_\gamma$, for some $\gamma \in I$. Hence, $b$ and $b$ belong to $A_\gamma$; so $bRa$ and $R$ is symmetric.

Finally, let $a, b$ and $c$ be elements of $A$ such that $aRa$ and $bRc$. Therefore, $a, b \in A_\beta$ and $b, c \in A_\gamma$, for some $\beta, \gamma \in I$. Since $P$ is a partition of $A$, the element $b$ belongs to only one set in $P$. Hence, $A_\beta = A_\gamma$ and so $a, c \in A_\beta$. Thus, $aRa$, $cRa$ and $R$ is transitive. Therefore, $R$ is an equivalence relation on $A$.

We now consider the equivalence classes resulting from $R$. Let $a \in A$. Then $a \in A_\alpha$ for some $\alpha \in I$. The equivalence class $[a]$ consists of all elements of $A$ related to $a$. From the way that $R$ is defined, however, the only elements related to $a$ are those elements belonging to the same subset in $P$ to which $a$ belongs, that is, $[a] = A_\alpha$. Hence,

$$[[a] : a \in A] = \{A_\alpha : \alpha \in I\} = P.$$  

With the added information we now have about equivalence classes, it is often easier to determine the distinct equivalence classes resulting from a given equivalence relation.

To illustrate this, we consider another example of an equivalence relation defined on the set of integers.

**Result to Prove** A relation $R$ is defined on $\mathbb{Z}$ by $x \sim y$ if $11x - 5y$ is even. Then $R$ is an equivalence relation.

**Proof Strategy** Since we want to verify that $R$ is an equivalence relation, we need to show that $R$ is reflexive, symmetric and transitive. Let’s start with the first of these. We begin with an integer $a$. To show that $aRa$, we need to show that $11a - 5a$ is even. However, $11a - 5a = 6a = 2(3a)$, so this shouldn’t cause any difficulties.

To verify that $R$ is symmetric, we begin with $aRa$ (where $a, b \in \mathbb{Z}$, of course) and attempt to show that $bRa$. Since $aRa$, it follows that $11a - 5b$ is even. To show that $bRa$, we need to show that $11b - 5a$ is even. Since $11a - 5b$ is even, we can write
238 Chapter 9 Equivalence Relations

$11a - 5b = 2k$ for some integer $k$. At first thought, it might seem like a good idea to solve for $a$ in terms of $b$ or solve for $b$ in terms of $a$. However, because neither the coefficient of $a$ nor the coefficient of $b$ is 1 or $-1$ in $11a - 5b = 2k$, fractions would be introduced. We need another approach. Notice that if we write

$11b - 5a = (11a - 5b) + (?a + ?b),$

then we have

$11b - 5a = (11a - 5b) + (-16a + 16b) = 2k - 16a + 16b = 2(k - 8a + 8b).$

This will work.

To verify that $R$ is transitive, we begin by assuming that $aRb$ and $bRc$ (and attempt to show that $aRc$). Thus, $11a - 5b$ and $11b - 5c$ are even and so

$11a - 5b = 2k$ and $11b - 5c = 2\ell,$

for integers $k$ and $\ell$. To show that $aRc$, we must verify that $11a - 5c$ is even. We need to work the expression $11a - 5c$ into the discussion. However, this can be done by adding the expressions in (9.5). We’re ready to give a proof now.

**Result 9.13** A relation $R$ is defined on $\mathbb{Z}$ by $xRy$ if $11x - 5y$ is even. Then $R$ is an equivalence relation.

**Proof** First, we show that $R$ is reflexive. Let $a \in \mathbb{Z}$. Then $11a - 5a = 6a = 2(3a).$ Since $3a$ is an integer, $11a - 5a$ is even. Thus, $aRa$ and $R$ is reflexive.

Next we show that $R$ is symmetric. Assume that $aRb$, where $a, b \in \mathbb{Z}$. Thus, $11a - 5b$ is even. Therefore, $11a - 5b = 2k$, where $k \in \mathbb{Z}$. Observe that

$11b - 5a = (11a - 5b) + (-16a + 16b) = 2k - 16a + 16b = 2(k - 8a + 8b).$

Since $k - 8a + 8b$ is an integer, $11b - 5a$ is even. Hence, $bRa$ and $R$ is symmetric.

Finally, we show that $R$ is transitive. Assume that $aRb$ and $bRc$. Hence, $11a - 5b$ and $11b - 5c$ are even. Therefore, $11a - 5b = 2k$ and $11b - 5c = 2\ell$, where $k, \ell \in \mathbb{Z}$. Adding these equations, we obtain $(11a - 5b) + (11b - 5c) = 2k + 2\ell.$ Solving for $11a - 5c$, we have

$11a - 5c = 2k + 2\ell - 6b = 2(k + \ell - 3b).$

Since $k + \ell - 3b$ is an integer, $11a - 5c$ is even. Hence, $aRc$ and $R$ is transitive. Therefore, $R$ is an equivalence relation.

We now determine the equivalence classes for the equivalence relation just discussed. Let’s begin with the equivalence class containing 0, say. Then

$[0] = \{x \in \mathbb{Z}: xR0\} = \{x \in \mathbb{Z}: 11x \text{ is even}\} = \{x \in \mathbb{Z}: x \text{ is even}\} = \{0, \pm2, \pm4, \ldots\}.$

Recall that the distinct equivalence classes always produce a partition of the set involved (in this case $\mathbb{Z}$). Since the class $[0]$ does not consist of all integers, there is at least one
other equivalence class. To determine another equivalence class, we look for an element that does not belong to \([0]\). Since \(1 \notin [0]\), the equivalence class \([1]\) is distinct (and disjoint) from \([0]\). Thus,
\[
[1] = \{x \in \mathbb{Z} : x \equiv 1 \pmod{3} \} = \{x \in \mathbb{Z} : 11x - 5 \text{ is even} \}
\]
\[
= \{x \in \mathbb{Z} : x \text{ is odd} \} = \{\pm 1, \pm 3, \pm 5, \ldots \}.
\]
Since \([0]\) and \([1]\) produce a partition of \(\mathbb{Z}\) (that is, every integer belongs to exactly one of \([0]\) and \([1]\)), these are the only equivalence classes in this case.

### SECTION 9.4 EXERCISES

9.36. Give an example of an equivalence relation \(R\) on the set \(A = \{v, w, x, y, z\}\) such that there are exactly three distinct equivalence classes. What are the equivalence classes for your example?

9.37. A relation \(R\) is defined on \(\mathbb{N}\) by \(a \mathrel{R} b\) if \(a^2 + b^2\) is even. Prove that \(R\) is an equivalence relation. Determine the distinct equivalence classes.

9.38. Let \(R\) be a relation defined on the set \(\mathbb{N}\) by \(a \mathrel{R} b\) if either \(a \mid 2b\) or \(b \mid 2a\). Prove or disprove: \(R\) is an equivalence relation.

9.39. Let \(S\) be a nonempty subset of \(\mathbb{Z}\) and let \(R\) be a relation defined on \(S\) by \(x \mathrel{R} y\) if \(3 \mid (x + 2y)\).

(a) Prove that \(R\) is an equivalence relation.

(b) If \(S = \{-7, -6, -2, 0, 1, 4, 5, 7\}\), then what are the distinct equivalence classes in this case?

9.40. A relation \(R\) is defined on \(\mathbb{Z}\) by \(x \mathrel{R} y\) if \(3x - 7y\) is even. Prove that \(R\) is an equivalence relation. Determine the distinct equivalence classes.

9.41. (a) Prove that the intersection of two equivalence relations on a nonempty set is an equivalence relation.

(b) Consider the equivalence relations \(R_2\) and \(R_3\) defined on \(\mathbb{Z}\) by \(a \mathrel{R_2} b\) if \(a \equiv b \pmod{2}\) and \(a \mathrel{R_3} b\) if \(a \equiv b \pmod{3}\). By (a), \(R_1 = R_2 \cap R_3\) is an equivalence relation on \(\mathbb{Z}\). Determine the distinct equivalence classes in \(R_1\).

9.42. Prove or disprove: The union of two equivalence relations on a nonempty set is an equivalence relation.

9.43. Let \(A = \{u, v, w, x, y, z\}\). The relation
\[
R = \{(u, u), (u, v), (u, w), (v, v), (v, w), (w, v), (w, w), (x, x), (y, y), (y, x), (z, z)\}
\]
defined on \(A\) is an equivalence relation. In particular, \([u] = [v] = [w] = \{u, v, w\}\), \([x] = [y] = \{x, y\}\) and \([z] = \{z\}\); so \(\|u\| = \|v\| = \|w\| = 3\) and \(\|x\| = \|y\| = 2\), while \(\|z\| = 1\). Therefore,
\[\|u\| + \|v\| + \|w\| + \|x\| + \|y\| + \|z\| = 14.\]

Let \(A = \{a_1, a_2, \ldots, a_n\}\) be an \(n\)-element set and let \(R\) be an equivalence relation defined on \(A\). Prove that \(\sum_{i=1}^{n} \|a_i\|\) is even if and only if \(n\) is even.

### 9.5 CONGRUENCE MODULO \(n\)

Next, we describe one of the most important equivalence relations. If you have more mathematics in your future, it is likely that you will see the equivalence relation we are about to describe again – indeed often. Recall that for integers \(a\) and \(b\), where \(a \neq 0\),
Chapter 9  Equivalence Relations

the integer \( a \) is said to divide \( b \), written as \( a \mid b \), if there exists an integer \( c \) such that \( b = ac \). Also, for integers \( a, b \) and \( n \geq 2 \), \( a \) is said to be congruent to \( b \) modulo \( n \), written \( a \equiv b \pmod{n} \), if \( n \mid (a - b) \). For example, \( 24 \equiv 6 \pmod{9} \) since \( 9 \mid (24 - 6) \); while \( 1 \equiv 5 \pmod{2} \) since \( 2 \mid (1 - 5) \). Also, \( 4 \equiv 4 \pmod{5} \) since \( 5 \mid (4 - 4) \). However, \( 8 \not\equiv 2 \pmod{4} \) since \( 4 \nmid (8 - 2) \). These concepts were introduced in Chapter 4.

Let’s consider a few examples of pairs \( a, b \) of integers such that \( a \equiv b \pmod{5} \). Notice that \( 7 \equiv 7 \pmod{5} \), \( -1 \equiv -1 \pmod{5} \) and \( 0 \equiv 0 \pmod{5} \). Also, \( 2 \equiv -8 \pmod{5} \) and \( -8 \equiv 2 \pmod{5} \). Notice also that \( 2 \equiv 17 \pmod{5} \). Therefore, both \(-8 \equiv 2 \pmod{5} \) and \( 2 \equiv 17 \pmod{5} \). Furthermore, \(-8 \equiv 17 \pmod{5} \). These examples might suggest that the reflexive, symmetric and transitive properties are satisfied here – a fact which we are about to verify. This is the important equivalence relation we referred to at the beginning of this section, not just for \( n = 5 \) but for any integer \( n \geq 2 \).

Theorem 9.14 Let \( n \in \mathbb{Z} \), where \( n \geq 2 \). Then congruence modulo \( n \) (that is, the relation \( R \) defined on \( \mathbb{Z} \) by \( aRb \) if \( a \equiv b \pmod{n} \)) is an equivalence relation on \( \mathbb{Z} \).

**Proof**

Let \( a \in \mathbb{Z} \). Since \( n \mid 0 \), it follows that \( n \mid (a - a) \) and so \( a \equiv a \pmod{n} \). Thus, \( aRa \), implying that \( R \) is reflexive.

Next, we show that \( R \) is symmetric. Assume that \( aRb \), where \( a, b \in \mathbb{Z} \). Since \( aRb \), it follows that \( a \equiv b \pmod{n} \) and so \( n \mid (a - b) \). Hence, there exists \( k \in \mathbb{Z} \) such that \( a - b = nk \). Thus,

\[
b - a = -(a - b) = -(nk) = n(-k).
\]

Since \(-k \in \mathbb{Z} \), it follows that \( n \mid (b - a) \) and so \( b \equiv a \pmod{n} \). Therefore, \( bRa \) and \( R \) is symmetric.

Finally, we show that \( R \) is transitive. Assume that \( aRb \) and \( bRc \), where \( a, b, c \in \mathbb{Z} \). We show that \( a Rc \). Since \( aRb \) and \( bRc \), it follows that \( a \equiv b \pmod{n} \) and \( b \equiv c \pmod{n} \). Thus, \( n \mid (a - b) \) and \( n \mid (b - c) \). Consequently,

\[
a - b = nk \quad \text{and} \quad b - c = n\ell \tag{9.6}
\]

for some integers \( k \) and \( \ell \). Adding the equations in (9.6), we obtain

\[
(a - b) + (b - c) = nk + n\ell = n(k + \ell);
\]

so \( a - c = n(k + \ell) \). Since \( k + \ell \in \mathbb{Z} \), we have \( n \mid (a - c) \) and so \( a \equiv c \pmod{n} \). Therefore, \( aRc \) and \( R \) is transitive.

**Proof Analysis**

Theorem 9.14 describes a well-known equivalence relation. Let’s review how we verified this. The proof we gave to show that congruence modulo \( n \) is an equivalence relation is a common proof technique for this kind of result and we need to be familiar with it. To prove that \( R \) is reflexive, we began with an arbitrary element of \( \mathbb{Z} \). We called this element \( a \). Our goal was to show that \( aRa \). By definition, \( aRa \) if and only if \( a \equiv a \pmod{n} \). However, \( a \equiv a \pmod{n} \) if and only if \( n \mid (a - a) \), which is the same as the statement \( n \mid 0 \). Clearly, \( n \mid 0 \) and this is where we decided to start.

To prove that \( R \) is symmetric, we started (as always) by assuming that \( aRb \). Our goal was to show that \( bRa \). Since \( aRb \), the definition of the relation \( R \) tells us that \( a \equiv b \pmod{n} \). From this, we knew that \( n \mid (a - b) \) and \( a - b = nk \) for some integer \( k \).
However, to show that \( b R a \), we needed to verify that \( b \equiv a \pmod{n} \). But this can only be done if we can show that \( n \mid (b - a) \) or, equivalently, that \( b - a = n\ell \) for some integer \( \ell \). Hence, we needed to verify that \( b - a \) can be expressed as the product of \( n \) and some other integer. Since \( b - a \) is the negative of \( a - b \) and we have a convenient expression for \( a - b \), this provided us with a key step.

Finally, to prove that \( R \) is transitive, we began by assuming that \( a R b \) and \( b R c \), which led us to the expressions \( a - b = nk \) and \( b - c = n\ell \), where \( k, \ell \in \mathbb{Z} \). Since our goal was to show that \( a R c \), we were required to show that \( a - c \) is a multiple of \( n \). Somehow then, we needed to work the term \( a - c \) into the problem, knowing that \( a - b = nk \) and \( b - c = n\ell \). The key step here was to observe that \( a - c = (a - b) + (b - c) \).

According to Theorem 9.14 then, congruence modulo 3 is an equivalence relation. In other words, if we define a relation \( R \) on \( \mathbb{Z} \) by \( a R b \) if \( a \equiv b \pmod{3} \), then it follows that \( R \) is an equivalence relation. Let’s determine the distinct equivalence classes in this case. First, select an integer, say 0. Then \( [0] \) is an equivalence class. Indeed,

\[
[0] = \{ x \in \mathbb{Z} : x R 0 \} = \{ x \in \mathbb{Z} : x \equiv 0 \pmod{3} \}
= \{ x \in \mathbb{Z} : 3 | x \} = \{ 0, \pm3, \pm6, \pm9, \ldots \}.
\]

Hence, the class \([0]\) consists of the multiples of 3. This class could be denoted by \([3], [6], [-300]\) or, in fact, by \([a]\) for any integer \( a \) which is a multiple of 3. Since there are integers not in \([0]\), there must be at least one equivalence class distinct from \([0]\). In particular, since \( 1 \notin [0] \), it follows that \([1] \neq [0] \), in fact, necessarily, \([1] \cap [0] = \emptyset \). The equivalence class

\[
[1] = \{ x \in \mathbb{Z} : x R 1 \} = \{ x \in \mathbb{Z} : x \equiv 1 \pmod{3} \}
= \{ x \in \mathbb{Z} : 3 | (x - 1) \} = \{ 1, -2, 4, -5, 7, -8, \ldots \}.
\]

Since \( 2 \notin [0] \) and \( 2 \notin [1] \), the equivalence class \([2] \) is different from both \([0] \) and \([1] \). By definition,

\[
[2] = \{ x \in \mathbb{Z} : x R 2 \} = \{ x \in \mathbb{Z} : x \equiv 2 \pmod{3} \}
= \{ x \in \mathbb{Z} : 3 | (x - 2) \} = \{ 2, -1, 5, -4, 8, -7, \ldots \}.
\]

Since every integer belongs to (exactly) one of these classes, we have exactly three distinct equivalence classes in this case, namely:

\[
[0] = \{ 0, \pm3, \pm6, \pm9, \ldots \},
[1] = \{ 1, -2, 4, -5, 7, -8, \ldots \},
[2] = \{ 2, -1, 5, -4, 8, -7, \ldots \}.
\]

These equivalence classes have a connection with the familiar concepts of division and remainders, which we encountered in Section 4.1 and which are useful to review here. If \( m \) and \( n \geq 2 \) are integers and \( m \) is divided by \( n \), then we can express this division as \( m = nq + r \), where \( q \) is the quotient and \( r \) is the remainder. The remainder \( r \) has the requirement that \( 0 \leq r < n \). With this requirement, \( q \) and \( r \) are unique and the result that we have just referred to is the Division Algorithm. (The Division Algorithm will be studied in considerably more detail in Chapter 12.) Consequently, every integer \( m \) can be expressed as \( 3q + r \), where \( r \in \{ 0, 1, 2 \} \).

Hence, every integer can be expressed as
Chapter 9  Equivalence Relations

3q, 3q + 1 or 3q + 2 for some integer q. In this case, the equivalence class [0] consists of the multiples of 3, and so every integer having a remainder of 0 when divided by 3 belongs to [0]. Furthermore, every integer having a remainder of 1 when divided by 3 belongs to [1]; while every integer having remainder of 2 when divided by 3 belongs to [2]. Since

\[ 73 = 24 \cdot 3 + 1 \quad \text{and} \quad -22 = (-8) \cdot 3 + 2, \]

for example, it follows that 73 \in [1] and -22 \in [2]. In fact, [73] = [1] and [-22] = [2].

In general, for \( n \geq 2 \), the equivalence relation of congruence modulo \( n \) results in \( n \) distinct equivalence classes. In other words, if we define \( a R b \) by \( a \equiv b \pmod{n} \), then there are \( n \) distinct equivalence classes: \([0],[1],\ldots,[n-1]\). In fact, for an integer \( r \) with \( 0 \leq r < n \), an integer \( m \) belongs to the set \([r]\) if and only if there is an integer \( q \) (the quotient) such that \( m = nq + r \). In fact, the equivalence class \([r]\) consists of all integers having a remainder of \( r \) when divided by \( n \).

Let’s consider another equivalence relation defined on \( \mathbb{Z} \) involving congruence but which is seemingly different from the class of examples we have just described.

**Result to Prove**

Let \( R \) be the relation defined on \( \mathbb{Z} \) by \( a R b \) if \( 2a + b \equiv 0 \pmod{3} \). Then \( R \) is an equivalence relation.

**Proof Strategy**

To prove that \( R \) is reflexive, we must show that \( x R x \) for every \( x \in \mathbb{Z} \). This means that we must show that \( 2x + x \equiv 0 \pmod{3} \) or that \( 3x \equiv 0 \pmod{3} \). This is equivalent to showing that \( 3 \mid 3x \), which is obvious. This tells us where to begin the proof of the reflexive property.

Proving that \( R \) is symmetric is somewhat more subtle. Of course, we know where to begin. We assume that \( x R y \). From this, we have \( 2x + y \equiv 0 \pmod{3} \). So, \( 3 \mid (2x + y) \) or \( 2x + y = 3r \) for some integer \( r \). Our goal is to show that \( y R x \) or, equivalently, that \( 2y + x \equiv 0 \pmod{3} \). Eventually then, we must show that \( 2y + x = 3s \) for some integer \( s \).

We cannot assume this of course. Since \( 2x + y = 3r \), it follows that \( y = 3r - 2x \). So

\[ 2y + x = 2(3r - 2x) + x = 6r - 3x = 3(2r - x). \]

Since \( 2r - x \in \mathbb{Z} \), we have \( 3 \mid (2y + x) \) and the verification of symmetry is nearly complete.

Proving that \( R \) is transitive should be as expected.

\[ \Box \]

**Result 9.15**

Let \( R \) be the relation defined on \( \mathbb{Z} \) by \( a R b \) if \( 2a + b \equiv 0 \pmod{3} \). Then \( R \) is an equivalence relation.

**Proof**

Let \( x \in \mathbb{Z} \). Since \( 3 \mid 3x \), it follows that \( 3x \equiv 0 \pmod{3} \). So, \( 2x + x \equiv 0 \pmod{3} \). Thus, \( x R x \) and \( R \) is reflexive.

Next we verify that \( R \) is symmetric. Assume that \( x R y \), where \( x, y \in \mathbb{Z} \). Thus, \( 2x + y \equiv 0 \pmod{3} \) and so \( 3 \mid (2x + y) \). Therefore, \( 2x + y = 3r \) for some integer \( r \). Hence, \( y = 3r - 2x \). So

\[ 2y + x = 2(3r - 2x) + x = 6r - 3x = 3(2r - x). \]

Since \( 2r - x \) is an integer, \( 3 \mid (2y + x) \). So, \( 2y + x \equiv 0 \pmod{3} \). Therefore, \( y R x \) and \( R \) is symmetric.
Finally, we show that $R$ is transitive. Assume that $x R y$ and $y R z$, where $x, y, z \in \mathbb{Z}$. Then $2x + y \equiv 0 \pmod{3}$ and $2y + z \equiv 0 \pmod{3}$. Thus, $3 \mid (2x + y)$ and $3 \mid (2y + z)$. From this, it follows that $2x + y = 3r$ and $2y + z = 3s$ for some integers $r$ and $s$. Adding these two equations, we obtain

$$2x + 3y + z = 3r + 3s;$$

so

$$2x + z = 3r + 3s - 3y = 3(r + s - y).$$

Since $r + s - y$ is an integer, $3 \mid (2x + z)$; so $2x + z \equiv 0 \pmod{3}$. Hence, $x R z$ and $R$ is transitive.

**Proof Analysis**

A few additional comments about the proof of the symmetric property in Result 9.15 might be helpful. At one point in the proof we knew that $2x + y = 3r$ for some integer $r$ and we wanted to show that $2y + x = 3s$ for some integer $s$. If we added these two equations, then we would obtain $3x + 3y = 3r + 3s$. Of course, we can’t add these because we don’t know that $2y + x = 3s$. But this does suggest another idea.

Assume that $x R y$. Thus, $2x + y \equiv 0 \pmod{3}$. Hence, $3 \mid (2x + y)$; so $2x + y = 3r$ for some integer $r$. Observe that

$$3x + 3y = (2x + y) + (2y + x) = 3r + (2y + x).$$

Therefore,

$$2y + x = 3x + 3y - 3r = 3(x + y - r).$$

Because $x + y - r \in \mathbb{Z}$, it follows that $3 \mid (2y + x)$. Consequently, $2y + x \equiv 0 \pmod{3}$, $y R x$ and $R$ is symmetric.

The distinct equivalence classes for the equivalence relation described in Result 9.15 are

$$[0] = \{x \in \mathbb{Z} : x R 0\} = \{x \in \mathbb{Z} : 2x \equiv 0 \pmod{3}\} = \{x \in \mathbb{Z} : 3 \mid 2x\} = \{0, \pm 3, \pm 6, \pm 9, \ldots\},$$

$$[1] = \{x \in \mathbb{Z} : x R 1\} = \{x \in \mathbb{Z} : 2x + 1 \equiv 0 \pmod{3}\} = \{x \in \mathbb{Z} : 3 \mid (2x + 1)\} = \{1, -2, 4, -5, 7, -8, \ldots\},$$

$$[2] = \{x \in \mathbb{Z} : x R 2\} = \{x \in \mathbb{Z} : 2x + 2 \equiv 0 \pmod{3}\} = \{x \in \mathbb{Z} : 3 \mid (2x + 2)\} = \{2, -1, 5, -4, 8, -7, \ldots\}.$$

Let’s discuss how we obtained these equivalence classes. We started with the integer 0 and saw that $[0] = \{x \in \mathbb{Z} : 3 \mid 2x\}$. By trying various values of $x$ (namely, 0, 1, 2, 3, 4, 5, etc. and $-1, -2, -3, -4$, etc), we see that we are obtaining the multiples of 3. (Exercise 4.6 asks you to show that if $3 \mid 2x$, then $x$ is a multiple of 3.) The contents of [1] and [2] can be justified, if necessary, in a similar manner.

We have seen that if we define a relation $R_1$ on $\mathbb{Z}$ by $a R_1 b$ if $a \equiv b \pmod{3}$, then we have three distinct equivalence classes; while if we define a relation $R_2$ on $\mathbb{Z}$ by $a R_2 b$ if $2a + b \equiv 0 \pmod{3}$, then we also have three distinct classes — in fact, the same equivalence classes. Let’s see why this is true.
244 Chapter 9 Equivalence Relations

Result 9.16 Let $a, b \in \mathbb{Z}$. Then $a \equiv b \pmod{3}$ if and only if $2a + b \equiv 0 \pmod{3}$.

Proof First, assume that $a \equiv b \pmod{3}$. Then $3 \mid (a - b)$ and so $a - b = 3x$ for some integer $x$. Thus, $a = 3x + b$. Now

$$2a + b = 2(3x + b) + b = 6x + 3b = 3(2x + b).$$

Since $2x + b$ is an integer, $3 \mid (2a + b)$ and so $2a + b \equiv 0 \pmod{3}$.

For the converse, assume that $2a + b \equiv 0 \pmod{3}$. Hence, $3 \mid (2a + b)$, which implies that $2a + b = 3y$ for some integer $y$. Thus, $b = 3y - 2a$. Observe that

$$a - b = a - (3y - 2a) = 3a - 3y = 3(a - y).$$

Since $a - y$ is an integer, $3 \mid (a - b)$ and so $a \equiv b \pmod{3}$.

We shouldn’t jump to the conclusion that just because we are dealing with an equivalence relation defined in terms of the integers modulo 3, we will necessarily have three distinct equivalence classes. For example, suppose that we define a relation $R$ on $\mathbb{Z}$ by $aRb$ if $a^2 \equiv b^2 \pmod{3}$. Then, here too, $R$ is an equivalence relation. In this case, however, there are only two distinct equivalence classes, namely:

$$[0] = \{0, \pm 3, \pm 6, \pm 9, \ldots \} \text{ and } [1] = \{\pm 1, \pm 2, \pm 4, \pm 5, \ldots \},$$

since whenever an integer $n$ has a remainder 1 or 2 when it is divided by 3, then $n^2$ has a remainder of 1 when it is divided by 3 (see Result 4.12).

SECTION 9.5 EXERCISES

9.44. Classify each of the following statements as true or false.
(a) $25 \equiv 9 \pmod{8}$, (b) $-17 \equiv 9 \pmod{8}$, (c) $-14 \equiv -14 \pmod{4}$, (d) $25 \equiv -3 \pmod{11}$.

9.45. A relation $R$ is defined on $\mathbb{Z}$ by $aRb$ if $3a + 5b \equiv 0 \pmod{8}$. Prove that $R$ is an equivalence relation.

9.46. Let $R$ be the relation defined on $\mathbb{Z}$ by $aRb$ if $a + b \equiv 0 \pmod{3}$. Show that $R$ is not an equivalence relation.

9.47. The relation $R$ on $\mathbb{Z}$ defined by $aRb$ if $a^2 \equiv b^2 \pmod{4}$ is known to be an equivalence relation. Determine the distinct equivalence classes.

9.48. The relation $R$ defined on $\mathbb{Z}$ by $xRy$ if $x^3 \equiv y^3 \pmod{4}$ is known to be an equivalence relation. Determine the distinct equivalence classes.

9.49. A relation $R$ is defined on $\mathbb{Z}$ by $aRb$ if $5a \equiv 2b \pmod{3}$. Prove that $R$ is an equivalence relation and determine the distinct equivalence classes.

9.50. A relation $R$ is defined on $\mathbb{Z}$ by $aRb$ if $2a + 2b \equiv 0 \pmod{4}$. Prove that $R$ is an equivalence relation and determine the distinct equivalence classes.

9.51. Let $R$ be the relation defined on $\mathbb{Z}$ by $aRb$ if $2a + 3b \equiv 0 \pmod{5}$. Prove that $R$ is an equivalence relation and determine the distinct equivalence classes.

9.52. Let $R$ be the relation defined on $\mathbb{Z}$ by $aRb$ if $a^2 \equiv b^2 \pmod{5}$. Prove that $R$ is an equivalence relation and determine the distinct equivalence classes.

9.53. For an integer $n \geq 2$, the relation $R$ defined on $\mathbb{Z}$ by $aRb$ if $a \equiv b \pmod{n}$ is an equivalence relation. Equivalently, $aRb$ if $a - b = kn$ for some $k \in \mathbb{Z}$. Define a relation $R$ on the set $\mathbb{R}$ of real numbers by $aRb$ if $a - b = k\pi$ for some $k \in \mathbb{Z}$. Is this relation $R$ on $\mathbb{R}$ an equivalence relation? If not, explain why. If yes, prove this and determine $[0]$, $[\pi]$ and $[\sqrt{2}]$. 

9.6 The Integers Modulo \( n \)

We have already seen that for each integer \( n \geq 2 \), the relation \( R \) defined on \( \mathbb{Z} \) by \( a \mathrel{R} b \) if \( a \equiv b \) (mod \( n \)) is an equivalence relation. Furthermore, this equivalence relation results in the \( n \) distinct equivalence classes \([0],[1],\ldots,[n-1]\). We denote the set of these equivalence classes by \( \mathbb{Z}_n \) and refer to this set as the integers modulo \( n \). Thus, \( \mathbb{Z}_3 = \{[0],[1],[2]\} \) and, in general,
\[
\mathbb{Z}_n = \{[0],[1],\ldots,[n-1]\}.
\]

Hence, each element \([r]\) of \( \mathbb{Z}_n \), where \( 0 \leq r < n \), is a set that contains infinitely many integers; indeed, as we have noted, \([r]\) consists of all those integers having the remainder \( r \) when divided by \( n \). For this reason, the elements of \( \mathbb{Z}_n \) are sometimes called residue classes.

Although it makes perfectly good sense to take the union and intersection of two elements of \( \mathbb{Z}_n \) since these elements are sets (in fact, subsets of \( \mathbb{Z} \)), it doesn’t make sense at this point to add or multiply two elements of \( \mathbb{Z}_n \). However, since the elements of \( \mathbb{Z}_n \) have the appearance of integers, say \([a]\) and \([b]\), where \( a, b \in \mathbb{Z} \), it does suggest the possibility of defining addition and multiplication in \( \mathbb{Z}_n \). We now discuss how these operations can be defined on the set \( \mathbb{Z}_n \).

Of course, we have seen addition and multiplication defined many times before. When we speak of addition and multiplication being operations on a set \( S \), we mean that for \( x, y \in S \), the sum \( x + y \) and the product \( xy \) should both belong to \( S \). For example, in the set \( \mathbb{Q} \) of rational numbers, the sum and product of two rational numbers \( a/b \) and \( c/d \) (so \( a, b, c, d \in \mathbb{Z} \) and \( b, d \neq 0 \)) are defined by
\[
\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd} \quad \text{and} \quad \frac{a}{b} \cdot \frac{c}{d} = \frac{ac}{bd},
\]
both of which are rational numbers and so belong to \( \mathbb{Q} \).

As we mentioned, if addition and multiplication are operations on a set \( S \), then \( x + y \in S \) and \( xy \in S \) for all \( x, y \in S \). Therefore, if \( T \) is a nonempty subset of \( S \) and \( x, y \in T \), then \( x + y \in S \) and \( xy \in S \). The set \( T \) is closed under addition if \( x + y \in T \) whenever \( x, y \in T \). Similarly, \( T \) is closed under multiplication if \( xy \in T \) whenever \( x, y \in T \). Necessarily, if addition and multiplication are operations on a set \( S \), then \( S \) is closed under addition and multiplication.

For example, addition and multiplication are operations on \( \mathbb{Z} \). If \( A \) and \( B \) denote the sets of even integers and odd integers, respectively, then \( A \) is closed under both addition and multiplication but \( B \) is closed under multiplication only.

Regardless of how one might define addition and multiplication in \( \mathbb{Z}_n \), we would certainly expect that the sum and product of two elements of \( \mathbb{Z}_n \) is also an element of \( \mathbb{Z}_n \). There appears to be a natural definition of addition and multiplication in \( \mathbb{Z}_n \); namely, for two equivalence classes \([a]\) and \([b]\) in \( \mathbb{Z}_n \), we define
\[
[a] + [b] = [a + b] \quad \text{and} \quad [a] \cdot [b] = [ab].
\] (9.7)

Let’s suppose that we are considering \( \mathbb{Z}_6 \), for example, where then \( \mathbb{Z}_6 = \{[0],[1],\ldots,[5]\} \). From the definitions of addition and multiplication that we just gave, \([1] + [3] = [1 + 3] = [4] \) and \([1] \cdot [3] = [1 \cdot 3] = [3] \). This certainly seems harmless enough
but let’s consider adding and multiplying two other equivalence classes, say [2] and [3]. Again, according to the definitions in (9.7), [2] + [3] = [2 + 3] = [5] and [2] · [3] = [2 · 3] = [6]. However, we have been expressing the elements of \( \mathbb{Z}_6 \) by [0], [1], [2], [3], [4] and [5] and we don’t explicitly see [2 · 3] = [6] among these elements. Since \( 6 \equiv 0 \pmod{6} \), it follows that 6 \( \in \{0\} \), that is, \([6] = [0]\). Also, the remainder is 0 when 6 is divided by 6 and so \([6] = [0]\). Therefore, [2] · [3] = [0]. By similar reasoning, [3] + [5] = [2] and [3] · [5] = [3]. In fact, the complete addition and multiplication tables for \( \mathbb{Z}_6 \) are given in Figure 9.2.

\[
\begin{array}{cccccc}
\end{array}
\]

\[
\begin{array}{cccccc}
  [0] & [0] & [0] & [0] & [0] & [0] & [0] \\
\end{array}
\]

\[
\text{Figure 9.2} \quad \text{The Addition and Multiplication Tables for } \mathbb{Z}_6
\]

If we add [1] to [0], add [1] to [1] and continue in this manner, then we obtain [0] + [1] = [1], [1] + [1] = [2], [2] + [1] = [3], \ldots, [5] + [1] = [6] = [0], [6] + [1] = [0] + [1] = [1], etc.; that is, we return to [0] and cycle through all the classes of \( \mathbb{Z}_6 \) again (and again). If, instead of \( \mathbb{Z}_6 \), we were dealing with \( \mathbb{Z}_{12} \), we would have \([0] + [1] = [1], [1] + [1] = [2], [2] + [1] = [3], \ldots, [11] + [1] = [12] = [0], [12] + [1] = [0] + [1] = [1], etc. and this should remind you of what occurs when a certain number of hours is added to a time (in hours), where, of course, 12 o’clock is represented here as 0 o’clock. (For example, if it is 11 o’clock now, what time will it be 45 hours from now?)

Although the definitions of addition and multiplication in \( \mathbb{Z}_n \) that we gave in (9.7) should seem quite reasonable and expected, there is a possible point of concern here that needs to be addressed. According to the definition of addition in \( \mathbb{Z}_6 \), [4] + [5] = [3]. However, the class [4], which consists of all integers \( x \) such that \( x \equiv 4 \pmod{6} \), need not be represented this way. Since \( 10 \in [4] \), it follows that \([10] = [4] \). Also, \([16] = [4] \) and \([−2] = [4] \), for example. Moreover, \([11] = [5] \), \([17] = [5] \) and \([−25] = [5] \). This brings up the question: Is adding the equivalence classes \([4] \) and \([5] \) the same as adding \([10] \) and \([−25] \)? According to the definition we have given, \([10] + [−25] = [−15] \). Luckily, \([−15] = [3] \) and so we obtain the same sum as before. But will this happen every time? That is, does the definition of the sum of the equivalence classes \([a] \) and \([b] \) that we gave in (9.7) depend on the representatives \( a \) and \( b \) of these classes? If the sum (or product) of two equivalence classes does not depend on the representatives, then we say that this sum (or product) is well-defined. We certainly would want this to be the case, which, fortunately, it is. More precisely, addition and multiplication in \( \mathbb{Z}_n \) are well-defined if whenever \([a] = [b] \) and \([c] = [d] \) in \( \mathbb{Z}_n \), then \([a + c] = [b + d] \) and \([ac] = [bd] \).

**Theorem 9.17** Addition in \( \mathbb{Z}_n \), \( n \geq 2 \), is well-defined.

**Proof** The set \( \mathbb{Z}_n \) is the set of equivalence classes resulting from the equivalence relation \( R \) defined on \( \mathbb{Z} \) by \( a R b \) if \( a \equiv b \pmod{n} \). Let \([a], [b], [c], [d] \in \mathbb{Z}_n \), where \([a] = [b] \) and

9.57. Let \( S = \mathbb{Z} \) and \( T = \{4k : k \in \mathbb{Z}\} \). Thus, \( T \) is a nonempty subset of \( S \).

   (a) Prove that \( T \) is closed under addition and multiplication.
   (b) If \( a \in S - T \) and \( b \in T \), is \( ab \in T \)?
   (c) If \( a \in S - T \) and \( b \in T \), is \( a + b \in T \)?
   (d) If \( a, b \in S - T \), is it possible that \( ab \in T \)?
   (e) If \( a, b \in S - T \), is it possible that \( a + b \in T \)?

9.58. Prove that the multiplication in \( \mathbb{Z}_n \), \( n \geq 2 \), defined by \([a][b] = [ab]\) is well-defined. (See Result 4.11.)

9.59. (a) Let \([a], [b] \in \mathbb{Z}_n\). If \([a] \cdot [b] = [0]\), does it follow that \([a] = [0]\) or \([b] = [0]\)?
   (b) How is the question in (a) answered if \( \mathbb{Z}_n \) is replaced by \( \mathbb{Z}_{10} \) by \( \mathbb{Z}_{11} \)?
   (c) For which integers \( n \geq 2 \) is the following statement true? (You are only asked to make a conjecture, not to provide a proof.) Let \([a], [b] \in \mathbb{Z}_n\), \( n \geq 2 \). If \([a] \cdot [b] = [0]\), then \([a] = [0]\) or \([b] = [0]\).

9.60. For integers \( m, n \geq 2 \) consider \( \mathbb{Z}_m \) and \( \mathbb{Z}_n \). Let \([a] \in \mathbb{Z}_m\) where \( 0 \leq a \leq m - 1 \). Then \( a, a + m \in [a] \) in \( \mathbb{Z}_m \). If \( a, a + m \in [b] \) for some \([b] \in \mathbb{Z}_n\), then what can be said of \( m \) and \( n \)?

9.61. (a) For integers \( m, n \geq 2 \) consider \( \mathbb{Z}_m \) and \( \mathbb{Z}_n \). If some element of \( \mathbb{Z}_m \) also belongs to \( \mathbb{Z}_n \), then what can be said of \( \mathbb{Z}_m \) and \( \mathbb{Z}_n \)?
   (b) Are there examples of integers \( m, n \geq 2 \) for which \( \mathbb{Z}_m \cap \mathbb{Z}_n = \emptyset \)?

Chapter 9 Supplemental Exercises

9.62. Prove or disprove:
   (a) There exists an integer \( a \) such that \( ab \equiv 0 \pmod{3} \) for every integer \( b \).
   (b) If \( a \in \mathbb{Z} \), then \( ab \equiv 0 \pmod{3} \) for every \( b \in \mathbb{Z} \).
   (c) For every integer \( a \), there exists an integer \( b \) such that \( ab \equiv 0 \pmod{3} \).

9.63. A relation \( R \) is defined on \( \mathbb{R} \) by \( a R b \) if \( a - b \in \mathbb{Z} \). Prove that \( R \) is an equivalence relation and determine the equivalence classes \([1/2]\) and \([\sqrt{2}]\).

9.64. A relation \( R \) is defined on \( \mathbb{Z} \) by \( a R b \) if \( |a - 2| = |b - 2| \). Prove that \( R \) is an equivalence relation and determine the distinct equivalence classes.

9.65. Let \( k \) and \( \ell \) be integers such that \( k + \ell \equiv 0 \pmod{3} \) and let \( a, b \in \mathbb{Z} \). Prove that if \( a \equiv b \pmod{3} \), then \( ka + \ell b \equiv 0 \pmod{3} \).

9.67. A relation \( R \) is defined on \( \mathbb{Z} \) by \( a R b \) if \( 3 \mid (a^3 - b) \). Prove or disprove the following:
   (a) \( R \) is reflexive.
   (b) \( R \) is transitive.

9.68. A relation \( R \) is defined on \( \mathbb{Z} \) by \( a R b \) if \( a \equiv b \pmod{2} \) and \( a \equiv b \pmod{3} \). Prove or disprove: \( R \) is an equivalence relation on \( \mathbb{Z} \).

9.69. A relation \( R \) is defined on \( \mathbb{Z} \) by \( a R b \) if \( a \equiv b \pmod{2} \) or \( a \equiv b \pmod{3} \). Prove or disprove: \( R \) is an equivalence relation on \( \mathbb{Z} \).

9.70. Determine each of the following.
   (a) \([4]^3 = [4][4][4]\) in \( \mathbb{Z}_{15} \)
   (b) \([7]^5 \) in \( \mathbb{Z}_{10} \)

9.71. Let \( S = \{(a, b) : a, b \in \mathbb{R}, a \neq 0\} \).
   (a) Show that the relation \( R \) defined on \( S \) by \( (a, b) R (c, d) \) if \( ad = bc \) is an equivalence relation.
Chapter 9 Supplemental Exercises 249

(b) Describe geometrically the elements of the equivalence classes [(1, 2)] and [(3, 0)].

9.72. In Exercise 9.19, a relation $R$ was defined on $\mathbb{Z}$ by $x R y$ if $x \cdot y \geq 0$, and we were asked to determine which of the properties reflexive, symmetric and transitive are satisfied.

(a) How would our answers have changed if $x \cdot y \geq 0$ was replaced by: (i) $x \cdot y \leq 0$, (ii) $x \cdot y > 0$, (iii) $x \cdot y \neq 0$, (iv) $x \cdot y$ is odd, (v) $x \cdot y$ is even, (vi) $x y \neq 2 \ (\text{mod}\ 3)$?

(b) What are some additional questions you could ask?

9.73. For the following statement $S$ and proposed proof, either (1) $S$ is true and the proof is correct, (2) $S$ is true and the proof is incorrect or (3) $S$ is false (and the proof is incorrect). Explain which of these occurs.

$S$: Every symmetric and transitive relation on a nonempty set is an equivalence relation.

**Proof** Let $R$ be a symmetric and transitive relation defined on a nonempty set $A$. We need only show that $R$ is reflexive. Let $x \in A$. We show that $x R x$. Let $y \in A$ such that $x R y$. Since $R$ is symmetric, $y R x$. Now $x R y$ and $y R x$. Since $R$ is transitive, $x R x$. Thus, $R$ is reflexive. $\square$

9.74. Evaluate the proposed proof of the following result.

**Result** A relation $R$ is defined on $\mathbb{Z}$ by $a R b$ if 3 $|$ $(a + 2b)$. Then $R$ is an equivalence relation.

**Proof** Assume that $a R a$. Then 3 $|$ $(a + 2a)$. Since $a + 2a = 3a$ and $a \in \mathbb{Z}$, it follows that 3 $|$ $3a$ or 3 $|$ $(a + 2a)$. Therefore, $a R a$ and $R$ is reflexive.

Next, we show that $R$ is symmetric. Assume that $a R b$. Then 3 $|$ $(a + 2b)$. So, $a + 2b = 3x$, where $x \in \mathbb{Z}$. Hence, $a = 3x - 2b$. Therefore,

$$b + 2a = b + 2(3x - 2b) = b + 6x - 4b = 6x - 3b = 3(2x - b).$$

Since $2x - b$ is an integer, 3 $|$ $(b + 2a)$. So, $b R a$ and $R$ is symmetric.

Finally, we show that $R$ is transitive. Assume that $a R b$ and $b R c$. Then 3 $|$ $(a + 2b)$ and 3 $|$ $(b + 2c)$. So, $a + 2b = 3x$ and $b + 2c = 3y$, where $x, y \in \mathbb{Z}$. Adding, we have $(a + 2b) + (b + 2c) = 3x + 3y$. So,

$$a + 2c = 3x + 3y - 3b = 3(x + y - b).$$

Since $x + y - b$ is an integer, 3 $|$ $(a + 2c)$. Hence, $a R c$ and $R$ is transitive. $\square$

9.75. (a) Show that the relation $R$ defined on $\mathbb{R} \times \mathbb{R}$ by $(a, b) R (c, d)$ if $|a| + |b| = |c| + |d|$ is an equivalence relation.

(b) Describe geometrically the elements of the equivalence classes [(1, 2)] and [(3, 0)].

9.76. Let $x \in \mathbb{Z}_m$ and $y \in \mathbb{Z}_n$, where $m, n \geq 2$. If $x \leq y$, then what can be said of $m$ and $n$?

9.77. Let $A$ be a nonempty set and let $B$ be a fixed subset of $A$. A relation $R$ is defined on $\mathcal{P}(A)$ by $X R Y$ if $X \cap B = Y \cap B$.

(a) Prove that $R$ is an equivalence relation.

(b) Let $A = \{1, 2, 3, 4\}$ and $B = \{1, 3, 4\}$. For $X = \{2, 3, 4\}$, determine $[X]$. 249
Chapter 9  Equivalence Relations

9.78. Let $R_1$ and $R_2$ be equivalence relations on a nonempty set $A$. Prove or disprove each of the following.
   (a) If $R_1 \cap R_2$ is reflexive, then so are $R_1$ and $R_2$.
   (b) If $R_1 \cap R_2$ is symmetric, then so are $R_1$ and $R_2$.
   (c) If $R_1 \cap R_2$ is transitive, then so are $R_1$ and $R_2$.

9.79. Prove that if $R$ is an equivalence relation on a set $A$, then the inverse relation $R^{-1}$ is an equivalence relation on $A$.

9.80. Let $R_1$ and $R_2$ be equivalence relations on a nonempty set $A$. A relation $R = R_1 R_2$ is defined on $A$ as follows: For $a, b \in A$, $a R b$ if there exists $c \in A$ such that $a R_1 c$ and $c R_2 b$. Prove or disprove: $R$ is an equivalence relation on $A$.

9.81. A relation $R$ on a nonempty set $S$ is called sequential if for every sequence $x, y, z$ of elements of $S$ (distinct or not), at least one of the ordered pairs $(x, y)$ and $(y, z)$ belongs to $R$. Prove or disprove: Every symmetric, sequential relation on a nonempty set is an equivalence relation.

9.82. Consider the subset $H = \{[3k] : k \in \mathbb{Z}\}$ of $\mathbb{Z}_{12}$.
   (a) Determine the distinct elements of $H$ and construct an addition table for $H$.
   (b) A relation $R$ on $\mathbb{Z}_{12}$ is defined by $[a] R [b]$ if $[a - b] \in H$. Show that $R$ is an equivalence relation and determine the distinct equivalence classes.

9.83. For elements $a, b \in \mathbb{Z}_n$, $n \geq 2$, $a = [c]$ and $b = [d]$ for some integers $c$ and $d$. Define $a - b = [c] - [d]$ as the equivalence class $[c - d]$. Let $H = \{x_1, x_2, \ldots, x_d\}$ be a subset of $\mathbb{Z}_n$, $n \geq 2$, such that a relation $R$ defined on $\mathbb{Z}_n$ by $a R b$ if $a - b \in H$ is an equivalence relation.
   (a) For each $a \in \mathbb{Z}_n$, determine the equivalence class $[a]$ and show that $[a]$ consists of $d$ elements.
   (b) Prove that $d \mid n$. 
10

Functions

If $R$ is a relation from a set $A$ to a set $B$ and $x$ is an element of $A$, then either $x$ is related to no elements of $B$ or $x$ is related to at least one element of $B$. In the latter case, it may occur that $x$ is related to all elements of $B$ or perhaps to exactly one element of $B$. If every element of $A$ is related to no elements of $B$, then $R$ is the empty set $\emptyset$. If every element of $A$ is related to all elements of $B$, then $R$ is the Cartesian product $A \times B$. However, if every element of $A$ is related to exactly one element of $B$, then we have the most studied relation of all: a function. Surely, you have encountered functions before, at least in calculus and precalculus. But it is likely that you have not studied functions in the manner we are about to describe here.

10.1 THE DEFINITION OF FUNCTION

Let $A$ and $B$ be nonempty sets. By a function $f$ from $A$ to $B$, written $f : A \rightarrow B$, we mean a relation from $A$ to $B$ with the property that every element $a$ in $A$ is the first coordinate of exactly one ordered pair in $f$. Since $f$ is a relation, the set $A$ in this case is the domain of $f$, denoted by $\text{dom}(f)$. The set $B$ is called the codomain of $f$.

For a function $f : A \rightarrow B$, let $(a, b) \in f$. Since $f$ contains only one ordered pair whose first coordinate is $a$, it follows that $b$ is the unique second coordinate of an ordered pair whose first coordinate is $a$; that is, if $(a, b) \in f$ and $(a, c) \in f$, then $b = c$. If $(a, b) \in f$, then we write $b = f(a)$ and refer to $b$ as the image of $a$ under the function $f$. Sometimes $f$ is said to map $a$ into $b$. Indeed, $f$ itself is sometimes called a mapping.

The set

$\text{range}(f) = \{b \in B : b$ is an image under $f$ of some element of $A\} = \{f(x) : x \in A\}$

is the range of $f$ and consists of the second coordinates of the elements of $f$. If $A$ is a finite set, then the function $f$ is a finite set and the number of elements in $f$ is $|A|$ since there is exactly one ordered pair in $f$ corresponding to each element of $A$. Throughout this chapter, as with earlier chapters, whenever we refer to cardinalities of sets, we are concerned with finite sets only.

Suppose that $f : A \rightarrow B$ and $g : A \rightarrow B$ are two functions from $A$ to $B$ and $a \in A$. Then $f$ and $g$ contain exactly one ordered pair having $a$ as its first coordinate, say $(a, x) \in f$ and $(a, y) \in g$. If the sets $f$ and $g$ are equal, then $(a, x)$ belongs to $g$ as well. Since $g$ contains
Chapter 10  Functions

only one ordered pair whose first coordinate is \(a\), it follows that \((a, x) = (a, y)\). But this implies that \(x = y\), that is, \(f(a) = g(a)\). Hence, it is natural to define two functions \(f : A \rightarrow B\) and \(g : A \rightarrow B\) to be equal, written \(f = g\), if \(f(a) = g(a)\) for all \(a \in A\).

Let \(A = \{1, 2, 3\}\) and \(B = \{w, x, y, z\}\). Then \(f_1 = \{(1, y), (2, w), (3, y)\}\) is a function from \(A\) to \(B\) and so we may write \(f_1 : A \rightarrow B\). On the other hand, \(f_2 = \{(1, x), (2, z), (3, y), (2, x)\}\) is not a function since there are two ordered pairs whose first coordinate is 2. In addition, \(f_3 = \{(1, z), (3, x)\}\) is not a function from \(A\) to \(B\) either because \(\text{dom}(f_3) \neq A\). On the other hand, \(f_3\) is a function from \(A - \{2\}\) to \(B\).

It is often convenient to “visualize” a function \(f : A \rightarrow B\) by representing the two sets \(A\) and \(B\) by diagrams and drawing an arrow (a directed line segment) from an element \(x \in A\) to its image \(f(x) \in B\). This is illustrated for the function \(f_1\) described above in Figure 10.1. Therefore, in order to represent a function in this way, exactly one directed line segment must leave each element of \(A\) and proceed to an element of \(B\).

![Figure 10.1](image)

A function \(f_1 : A \rightarrow B\)

In calculus, “functions” such as \(f(x) = x^2\) are considered. This function \(f\) is from \(\mathbb{R}\) to \(\mathbb{R}\), that is, \(A = \mathbb{R}\) and \(B = \mathbb{R}\). Although \(f(x) = x^2\) is commonly referred to as a “function” in calculus and elsewhere, strictly speaking \(f(x)\) is the image of a real number \(x\) under \(f\). The function \(f\) itself is actually the set

\[ f = \{(x, x^2) : x \in \mathbb{R}\}. \]

So \((2, 4)\) and \((-3, 9)\), for example, belong to \(f\). The set \(\{(x, x^2) : x \in \mathbb{R}\}\) of points in the plane is the graph of \(f\). In this case, the graph is a parabola. Here, the function \(f : \mathbb{R} \rightarrow \mathbb{R}\) defined by \(f(x) = x^2\) can also be thought of as defined by a rule, namely the rule that associates the number \(x^2\) with each real number \(x\).

Example 10.1  Another function encountered in calculus is \(g(x) = e^x\). As we mentioned above, this function is actually the set

\[ g = \{(x, e^x) : x \in \mathbb{R}\}. \]

More precisely, this is the function \(g : \mathbb{R} \rightarrow \mathbb{R}\) defined by \(g(x) = e^x\) for all \(x \in \mathbb{R}\). In general, we will follow this latter convention for defining functions that are often described by some rule or formula. Consequently, the function \(h(x) = \frac{1}{x - 1}\) from calculus is the function \(h : \mathbb{R} - \{1\} \rightarrow \mathbb{R}\) defined by \(h(x) = \frac{1}{x - 1}\) for all \(x \in \mathbb{R}\) with \(x \neq 1\) and the function \(\phi(x) = \ln x\) is the function \(\phi : \mathbb{R}^+ \rightarrow \mathbb{R}\) defined by \(\phi(x) = \ln x\) for all \(x \in \mathbb{R}^+\), where, recall, \(\mathbb{R}^+\) is the set of all positive real numbers.
For a function \( f : A \rightarrow B \) and a subset \( C \) of \( A \), the **image** \( f(C) \) of \( C \) is defined as
\[
\text{f}(C) = \{ f(x) : x \in C \}.
\]
Therefore, \( f(C) \subseteq B \) for each subset \( C \) of \( A \). If \( C = A \), then \( f(A) \) is the range of \( f \).

**Example 10.2**

For \( A = \{a, b, c, d, e\} \) and \( B = \{1, 2, \ldots, 6\} \),
\[
f = \{(a, 3), (b, 5), (c, 2), (d, 3), (e, 6)\}
\]
is a function from \( A \) to \( B \). For \( C_1 = \{a, b, c\}, C_2 = \{a, d\}, C_3 = \{e\} \) and \( C_4 = A \),
\[
f(C_1) = \{2, 3, 5\}, f(C_2) = \{3\}, f(C_3) = \{6\}, f(C_4) = \text{range}(f) = \{2, 3, 5, 6\}.
\]

For a function \( f : A \rightarrow B \) and an element \( b \in B \), the **inverse image** \( f^{-1}(b) \) of \( b \) is defined as
\[
f^{-1}(b) = \{ a \in A : f(a) = b \}.
\]
Therefore, \( f^{-1}(b) \subseteq A \) for each element \( b \in B \). For a subset \( D \) of \( B \),
\[
f^{-1}(D) = \{ a \in A : f(a) \in D \}.
\]
Necessarily then, \( f^{-1}(B) = A \).

**Example 10.3**

For the function \( f : A = \{a, b, c, d, e\} \rightarrow B = \{1, 2, \ldots, 6\} \) defined in Example 10.2 by
\[
f = \{(a, 3), (b, 5), (c, 2), (d, 3), (e, 6)\},
\]
it follows that \( f^{-1}(3) = \{a, d\}, f^{-1}(1, 3) = \{a, d\}, f^{-1}(4) = \emptyset \) and \( f^{-1}(B) = A \).

Among the many classes of functions encountered in calculus are the polynomial functions, rational functions and exponential functions. The function \( f : \mathbb{R} \rightarrow \mathbb{R} \) defined earlier by \( f(x) = x^2 \) for \( x \in \mathbb{R} \) is a polynomial function. The function \( h : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( h(x) = \frac{1}{x-1} \) in Example 10.1 is a rational function and the function \( g : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( g(x) = e^x \) (also in Example 10.1) is an exponential function. Other important classes of functions encountered often in calculus are continuous functions and differentiable functions.

The definition of function that we have given is most likely not the definition you recall from calculus; in fact, you may not recall the definition of function given in calculus at all. If this is the case, then this is not surprising. The evolution of what is meant by a function has spanned hundreds of years. It was in the development of calculus that the necessity of a formal definition of function became apparent.

Early in the 18th century, the Swiss mathematician Johann Bernoulli wrote:

*I call a function of a variable magnitude a quantity composed in any manner whatsoever from this variable magnitude and from constants.*

Later in the 18th century, the famous Swiss mathematician Leonhard Euler studied calculus as a theory of functions and did not appeal to diagrams and geometric
interpretations, as many of his predecessors had done. The definition of function that Euler gave in his work on calculus is:

*A function of a variable quantity is an analytic expression composed in any way whatsoever of the variable quantity and numbers or constant quantities.*

Early in the 19th century, the German mathematician Peter Dirichlet developed a more modern definition of function:

*y is a function of x when to each value of x in a given interval there corresponds a unique value of y.*

Dirichlet said that it didn’t matter whether \( y \) depends on \( x \) according to some formula, law or mathematical operation. He emphasized this by considering the function \( f : \mathbb{R} \to \mathbb{R} \) defined by

\[
 f = \begin{cases} 
 1 & \text{if } x \text{ is rational} \\
 0 & \text{if } x \text{ is irrational}.
\end{cases}
\]

Later in the 19th century, the German mathematician Richard Dedekind wrote:

*A function \( \phi \) on a set \( S \) is a law according to which to every determinate element \( s \) of \( S \) there belongs a determinate thing which is called the transform of \( s \) and is denoted by \( \phi(s) \).*

So, by this time, the modern definition of function had nearly arrived.

Even if two sets \( A \) and \( B \) have relatively few elements, there are many possible functions from \( A \) to \( B \) that can be defined. For nonempty sets \( A \) and \( B \), the set of all functions from \( A \) to \( B \) is denoted by \( B^A \). That is, \( B^A = \{ f : f \text{ is a function from } A \text{ to } B \} \) or, more simply,

\[
 B^A = \{ f : f : A \to B \}.
\]

Although this notation may seem a bit peculiar, it is actually quite logical. For example, let’s determine \( B^A \) for the sets \( A = \{ a, b \} \) and \( B = \{ x, y, z \} \). Each function \( f \) from \( A \) to \( B \) is necessarily of the form

\[
 f = \{ (a, \alpha), (b, \beta) \},
\]

where \( \alpha, \beta \in B \). Since there are 3 choices for \( \alpha \) and 3 choices for \( \beta \), the total number of such functions \( f \) is \( 3 \cdot 3 = 3^2 = 9 \). These nine functions are listed below:

\[
 f_1 = \{ (a, x), (b, x) \}, \quad f_2 = \{ (a, x), (b, y) \}, \quad f_3 = \{ (a, x), (b, z) \}, \\
 f_4 = \{ (a, y), (b, x) \}, \quad f_5 = \{ (a, y), (b, y) \}, \quad f_6 = \{ (a, y), (b, z) \}, \\
 f_7 = \{ (a, z), (b, x) \}, \quad f_8 = \{ (a, z), (b, y) \}, \quad f_9 = \{ (a, z), (b, z) \}.
\]

Hence, the number of elements in \( B^A \) is \( 3^2 \). In general, for finite sets \( A \) and \( B \), the number of functions from \( A \) to \( B \) is

\[
 |B^A| = |B|^{|A|}.
\]

If \( B = \{0, 1\} \), then it is common to represent the set of all functions from \( A \) to \( B \) by \( 2^A \).

So, for the sets \( A = \{ a, b \} \) and \( B = \{ x, y, z \} \) above, the set of all functions from \( B \) to \( A \) is \( A^B \) and the number of such functions is \( |A|^{|B|} = 2^3 = 8 \).
SECTION 10.1 EXERCISES

10.1. Let \( A = \{a, b, c, d\} \) and \( B = \{x, y, z\} \). Then \( f = \{(a, y), (b, z), (c, y), (d, z)\} \) is a function from \( A \) to \( B \). Determine \( \text{dom}(f) \) and \( \text{range}(f) \).

10.2. Let \( A = \{1, 2, 3\} \) and \( B = \{a, b, c, d\} \). Give an example of a relation \( R \) from \( A \) to \( B \) containing exactly three elements such that \( R \) is not a function from \( A \) to \( B \). Explain why \( R \) is not a function.

10.3. Let \( A \) be a nonempty set. If \( R \) is a relation from \( A \) to \( A \) that is both an equivalence relation and a function, then what familiar function is \( R \)? Justify your answer.

10.4. For the given subset \( A_i \) of \( \mathbb{R} \) and the relation \( R_i \) (\( 1 \leq i \leq 3 \)) from \( A_i \) to \( \mathbb{R} \), determine whether \( R_i \) is a function from \( A_i \) to \( \mathbb{R} \).

(a) \( A_1 = \mathbb{R}, R_1 = \{(x, y) : x \in A_1, y = 4x - 3\} \)
(b) \( A_2 = [0, \infty), R_2 = \{(x, y) : x \in A_2, (y + 2)^2 = x\} \)
(c) \( A_3 = \mathbb{R}, R_3 = \{(x, y) : x \in A_3, (x + y)^2 = 4\} \)

10.5. Let \( A \) and \( B \) be nonempty sets and let \( R \) be a nonempty relation from \( A \) to \( B \). Show that there exists a subset \( A' \) of \( A \) and a subset \( f \) of \( R \) such that \( f \) is a function from \( A' \) to \( B \).

10.6. In each of the following, a function \( f_i : A_i \to \mathbb{R} \) (\( 1 \leq i \leq 5 \)) is defined, where the domain \( A_i \) consists of all possible real numbers \( x \) for which \( f_i(x) \) is defined. In each case, determine the domain \( A_i \) and the range of \( f_i \).

(a) \( f_1(x) = 1 + x^2 \) (b) \( f_2(x) = 1 - \frac{1}{x} \) (c) \( f_3(x) = \sqrt[3]{3x - 4} \)
(d) \( f_4(x) = x^3 - 8 \) (e) \( f_5(x) = \frac{x - 3}{x + 3} \)

10.7. Let \( A = \{3, 17, 29, 45\} \) and \( B = \{4, 6, 22, 60\} \). A relation \( R \) from \( A \) to \( B \) is defined by \( a R b \) if \( a + b \) is a prime. Is \( R \) a function from \( A \) to \( B \)?

10.8. Let \( A = \{5, 6\}, B = \{5, 7, 8\} \) and \( S = \{n : n \geq 3 \text{ is an odd integer}\} \). A relation \( R \) from \( A \times B \) to \( S \) is defined as \( (a, b) R s \) if \( s \mid (a + b) \). Is \( R \) a function from \( A \times B \) to \( S \)?

10.9. Determine which of the following five relations \( R_i \) (\( i = 1, 2, \ldots, 5 \)) are functions.

(a) \( R_1 \) is defined on \( \mathbb{R} \) by \( x R_1 y \) if \( x^2 + y^2 = 1 \).
(b) \( R_2 \) is defined on \( \mathbb{R} \) by \( x R_2 y \) if \( 4x^2 + 3y^2 = 1 \).
(c) \( R_3 \) is defined from \( \mathbb{N} \) to \( \mathbb{Q} \) by \( a R_3 b \) if \( 3a + 5b = 1 \).
(d) \( R_4 \) is defined on \( \mathbb{R} \) by \( x R_4 y \) if \( y = 4 - |x - 2| \).
(e) \( R_5 \) is defined on \( \mathbb{R} \) by \( x R_5 y \) if \( |x + y| = 1 \).

10.10. A function \( g : \mathbb{Q} \to \mathbb{Q} \) is defined by \( g(r) = 4r + 1 \) for each \( r \in \mathbb{Q} \).

(a) Determine \( g(\mathbb{Z}) \) and \( g(\mathbb{E}) \), where \( \mathbb{E} \) is the set of even integers.
(b) Determine \( g^{-1}(\mathbb{N}) \) and \( g^{-1}(\mathbb{D}) \), where \( \mathbb{D} \) is the set of odd integers.

10.11. Let \( C = \{x \in \mathbb{R} : x \geq 1\} \) and \( D = \mathbb{R}^+ \). For each function \( f \) defined below, determine \( f(C), f^{-1}(C), f^{-1}(D) \) and \( f^{-1}([1]) \).

(a) \( f : \mathbb{R} \to \mathbb{R} \) is defined by \( f(x) = x^2 \).
(b) \( f : \mathbb{R}^+ \to \mathbb{R} \) is defined by \( f(x) = \ln x \).
(c) \( f : \mathbb{R} \to \mathbb{R} \) is defined by \( f(x) = e^x \).
(d) \( f : \mathbb{R} \to \mathbb{R} \) is defined by \( f(x) = \sin x \).
(e) \( f : \mathbb{R} \to \mathbb{R} \) is defined by \( f(x) = 2x - x^2 \).
Chapter 10 Functions

10.12. For a function $f : A \rightarrow B$ and subsets $C$ and $D$ of $A$ and $E$ and $F$ of $B$, prove the following.
   
   (a) $f(C \cup D) = f(C) \cup f(D)$
   (b) $f(C \cap D) \subseteq f(C) \cap f(D)$
   (c) $f(C) - f(D) \subseteq f(C) - D$
   (d) $f^{-1}(E \cup F) = f^{-1}(E) \cup f^{-1}(F)$
   (e) $f^{-1}(E \cap F) = f^{-1}(E) \cap f^{-1}(F)$
   (f) $f^{-1}(E - F) = f^{-1}(E) - f^{-1}(F)$.

10.13. Determine $B^k$ for the sets $A = \{1, 2, 3\}$ and $B = \{x, y\}$.

10.14. For sets $A = \{1, 2, 3, 4\}$ and $B = \{x, y, z\}$, give an example of a function $g \in B^A$ and a function $h \in B^B$.

10.15. For $A = \{a, b, c\}$, determine $2^A$.

10.16. (a) Give an example of sets $A$ and $B$ such that $|B^A| = 8$.
   (b) Give an example of an element in $B^A$ for the sets $A$ and $B$ given in (a).

10.17. (a) For nonempty sets $A$, $B$ and $C$, what is a possible interpretation of the notation $C^{B^A}$?
   (b) According to the definition given in (a), determine $C^{B^A}$ for $A = \{0, 1\}$, $B = \{a, b\}$ and $C = \{x, y\}$.

10.2 ONE-TO-ONE AND ONTO FUNCTIONS

We now consider two of the most important properties that a function may possess. A function $f$ from a set $A$ to a set $B$ is called **one-to-one** or **injective** if every two distinct elements of $A$ have distinct images in $B$. In symbols, a function $f : A \rightarrow B$ is one-to-one if whenever $x, y \in A$ and $x \neq y$, then $f(x) \neq f(y)$. Thus, if a function $f : A \rightarrow B$ is not one-to-one, then there exist distinct elements $w$ and $z$ in $A$ such that $f(w) = f(z)$.

Let $A = \{a, b, c, d\}$, $B = \{r, s, t, u, v\}$ and $C = \{x, y, z\}$. Then

$$f_1 = \{(a, s), (b, u), (c, v), (d, r)\}$$

is a one-to-one function from $A$ to $B$ since distinct elements of $A$ have distinct images in $B$; while the function

$$f_2 = \{(a, s), (b, t), (c, s), (d, u)\}$$

from $A$ to $B$ is not one-to-one since $a$ and $c$ have the same image, namely $s$. There is no one-to-one function from $A$ to $C$, however.

Suppose that a function $f : A \rightarrow B$ is one-to-one, where $A$ and $B$ are finite sets. Since every two elements of $A$ have distinct images in $B$, there must be at least as many elements in $B$ as in $A$, that is, $|A| \leq |B|$.

At times, the definition of a one-to-one function is difficult to work with since it deals with unequal elements. However, there is a useful equivalent formulation of the definition using the contrapositive:

A function $f : A \rightarrow B$ is **one-to-one** if whenever $f(x) = f(y)$, where $x, y \in A$, then $x = y$.

The following result illustrates how this formulation can be applied to functions defined by formulas.

**Result 10.4** The function $f : \mathbb{R} \rightarrow \mathbb{R}$ defined by $f(x) = 3x - 5$ is one-to-one.
Proof Assume that \( f(a) = f(b) \), where \( a, b \in \mathbb{R} \). Then \( 3a - 5 = 3b - 5 \). Adding 5 to both sides, we obtain \( 3a = 3b \). Dividing by 3, we have \( a = b \) and so \( f \) is one-to-one. 

Example 10.5 Let the function \( f : \mathbb{R} \to \mathbb{R} \) be defined by \( f(x) = x^2 - 3x - 2 \). Determine whether \( f \) is one-to-one.

Solution Since \( f(0) = -2 \) and \( f(3) = -2 \), it follows that \( f \) is not one-to-one.

Analysis To show that the function \( f \) defined in Example 10.5 is not one-to-one, we must show that there exist two distinct real numbers having the same image under \( f \). This was accomplished by showing that \( f(0) = f(3) \). But what if we can’t find two real numbers with this property? Naturally, if we can’t find two such numbers, then we might think that \( f \) is one-to-one. In that case, we should be trying to prove that \( f \) is one-to-one. We would probably begin such a proof by assuming that \( f(a) = f(b) \), that is \( a^2 - 3a - 2 = b^2 - 3b - 2 \). We would then try to show that \( a = b \). We can simplify \( a^2 - 3a - 2 = b^2 - 3b - 2 \) by adding 2 to both sides, producing \( a^2 - 3a = b^2 - 3b \). When attempting to solve an equation, it is often convenient to collect all terms on one side of the equation with 0 on the other side. Rewriting this equation, we obtain \( a^2 - 3a - b^2 + 3b = 0 \). Rearranging some terms and factoring, we have
\[
a^2 - 3a - b^2 + 3b = (a^2 - b^2) - 3(a - b) = (a - b)(a + b) - 3(a - b) = (a - b)(a + b - 3) = 0.
\]

Hence, if \( f(a) = f(b) \), then \((a - b)(a + b - 3) = 0\). Since \((a - b)(a + b - 3) = 0\), it follows that either \(a - b = 0\) (and so \(a = b\)) or \(a + b - 3 = 0\). Therefore, \(f(a) = f(b)\) does not imply that \(a = b\). It only implies that \(a = b\) or \(a + b = 3\). Since \(0 + 3 = 3\), we now see why \(f(0) = f(3)\). In fact, if \(a\) and \(b\) are any two real numbers where \(a + b = 3\), then \(f(a) = f(b)\). This tells us how to find all possible counterexamples to the statement: \(f\) is one-to-one. Looking at \(f(x) = x^2 - 3x - 2\) once again, we see that \(f(x) = x(x - 3) - 2\). Since \(x(x - 3) = 0\) if \(x = 0\) or \(x = 3\), it is now more apparent why \(0\) and \(3\) are numbers for which \(f(0) = f(3)\).

A function \(f : A \to B\) is called **onto** or **surjective** if every element of the codomain \(B\) is the image of some element of \(A\). Equivalently, \(f\) is onto if \(f(A) = B\).

For example, consider the function \(f_1 : A \to B\), where \(A = \{1, 2, 3\}, B = \{x, y, z, w\}\) and \(f_1 = \{(1, y), (2, w), (3, y)\}\). This function \(f_1\) is **not** onto since neither \(x\) nor \(z\) is an image of some element of \(A\). You might notice that for these two sets \(A\) and \(B\), there is no function from \(A\) to \(B\) that is onto since any such function has exactly three ordered pairs but \(B\) has four elements. Thus, if \(A\) and \(B\) are finite sets and \(f : A \to B\) is a surjective function, then \(|B| \leq |A|\). The function \(g : B \to A\) where \(g = \{(x, 3), (y, 1), (z, 3), (w, 2)\}\) is a surjective function, however, since each of the elements 1, 2 and 3 is an image of some element of \(B\). Next, we determine which of the functions defined in Result 10.4 and Example 10.5 are onto.

Result to Prove The function \(f : \mathbb{R} \to \mathbb{R}\) defined by \(f(x) = 3x - 5\) is onto.

PROOF STRATEGY Let’s make a few observations before we begin the proof. To show that \(f\) is onto, we must show that every element in the codomain \(B = \mathbb{R}\) is the image of some element in the domain \(A = \mathbb{R}\). Since \(f(0) = -5\) and \(f(1) = -2\), certainly \(-5\) and \(-2\) are images
of elements of \( \mathbb{R} \). The real number 10 is an image as well since \( f(5) = 10 \). Is \( \pi \) an image of some real number? To answer this question, we need to determine whether there is a real number \( x \) such that \( f(x) = \pi \). Since \( f(x) = 3x - 5 \), we need only find a solution for \( x \) to the equation \( 3x - 5 = \pi \). Solving this equation for \( x \), we find that \( x = (\pi + 5)/3 \), which, of course, is a real number. Finally, observe that

\[
f(x) = f \left( \frac{\pi + 5}{3} \right) = 3 \left( \frac{\pi + 5}{3} \right) - 5 = \pi.
\]

This discussion, however, gives us the information we need to prove that \( f \) is onto since for an arbitrary real number \( r \), say, we need to find a real number \( x \) such that \( f(x) = r \). However, then, \( 3x - 5 = r \) and \( x = (r + 5)/3 \).

**Result 10.6** The function \( f : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( f(x) = 3x - 5 \) is onto.

**Proof** Let \( r \in \mathbb{R} \). We show that there exists \( x \in \mathbb{R} \) such that \( f(x) = r \). Choose \( x = (r + 5)/3 \). Then \( x \in \mathbb{R} \) and

\[
f(x) = f \left( \frac{r + 5}{3} \right) = 3 \left( \frac{r + 5}{3} \right) - 5 = r.
\]

**PROOF ANALYSIS** Notice that the proof itself of Result 10.6 does not include consideration of the equation \( 3x - 5 = r \). Our goal was to show that some real number \( x \) exists such that \( f(x) = r \). How we obtain this number, though possibly interesting, is not part of the proof. On the other hand, it may be a good idea to accompany the proof with this information.

The function \( f : \mathbb{R} \rightarrow \mathbb{R} \) defined in Example 10.5 by \( f(x) = x^2 - 3x - 2 \) is not onto, however. Writing \( x^2 - 3x - 2 \) as \( (x^2 - 3x + \frac{9}{4}) - 2 - \frac{9}{4} = (x - \frac{3}{2})^2 - \frac{17}{4} \), we see that \( f(x) \geq -\frac{17}{4} \). Thus, for each real number \( r \) with \( r < -\frac{17}{4} \), there is no \( x \in \mathbb{R} \) such that \( f(x) = r \). In fact, the range of \( f \) is \([-\frac{17}{4}, \infty)\).

Let \( A = \{1, 2, 3\} \), \( B = \{x, y, z, w\} \) and \( C = \{a, b, c\} \). Four functions \( g_1 : A \rightarrow B \), \( g_2 : B \rightarrow C \), \( g_3 : A \rightarrow C \) and \( g_4 : A \rightarrow C \) are defined as follows:

- \( g_1 = \{(1, y), (2, w), (3, x)\} \)
- \( g_2 = \{(x, b), (y, a), (z, c), (w, b)\} \)
- \( g_3 = \{(1, a), (2, c), (3, b)\} \)
- \( g_4 = \{(1, b), (2, b), (3, b)\} \)

The functions \( g_1 \) and \( g_3 \) are one-to-one; while \( g_2 \) and \( g_4 \) are not one-to-one since \( g_2(x) = g_2(w) = b \) and \( g_4(1) = g_4(2) = b \). Both \( g_2 \) and \( g_3 \) are onto. The function \( g_1 \) is not onto because \( z \) is not an image of any element of \( A \); while \( g_4 \) is not onto since neither \( a \) nor \( c \) is an image of an element of \( A \).

**SECTION 10.2 EXERCISES**

10.18. Let \( A = \{w, x, y, z\} \) and \( B = \{r, s, t\} \). Give an example of a function \( f : A \rightarrow B \) that is neither one-to-one nor onto. Explain why \( f \) fails to have these properties.

10.19. Give an example of two finite sets \( A \) and \( B \) and two functions \( f : A \rightarrow B \) and \( g : B \rightarrow A \) such that \( f \) is one-to-one but not onto and \( g \) is onto but not one-to-one.
A function \( f : \mathbb{Z} \to \mathbb{Z} \) is defined by \( f(n) = 2n + 1 \). Determine whether \( f \) is (a) injective, (b) surjective.

A function \( f : \mathbb{Z} \to \mathbb{Z} \) is defined by \( f(n) = n - 3 \). Determine whether \( f \) is (a) injective, (b) surjective.

A function \( f : \mathbb{Z} \to \mathbb{Z} \) is defined by \( f(n) = 5n + 2 \). Determine whether \( f \) is (a) injective, (b) surjective.

Prove or disprove: For every nonempty set \( A \), there exists an injective function \( f : A \to P(A) \).

Determine whether the function \( f : \mathbb{R} \to \mathbb{R} \) defined by \( f(x) = x^2 + 4x + 9 \) is (a) one-to-one, (b) onto.

Is there a function \( f : \mathbb{R} \to \mathbb{R} \) that is onto but not one-to-one? Explain your answer.

Give an example of a function \( f : \mathbb{N} \to \mathbb{N} \) that is
(a) one-to-one and onto
(b) one-to-one but not onto
(c) onto but not one-to-one
(d) neither one-to-one nor onto.

Let \( A = \{2, 3, 4, 5\} \) and \( B = \{6, 8, 10\} \). A relation \( R \) is defined from \( A \) to \( B \) by \( a R b \) if \( a \mid b \) and \( (b/a) + 1 \) is a prime.

(a) Is \( R \) a function from \( A \) to \( B \)?
(b) If \( R \) is a function from \( A \) to \( B \), then determine whether this function is one-to-one and/or onto.

Let \( A = \{2, 4, 6\} \) and \( B = \{1, 3, 4, 7, 9\} \). A relation \( f \) is defined from \( A \) to \( B \) by \( a f b \) if \( 5 \) divides \( ab + 1 \). Is \( f \) a one-to-one function?

Let \( f \) be a function with \( \text{dom}(f) = A \) and let \( C \) and \( D \) be subsets of \( A \). Prove that if \( f \) is one-to-one, then \( f(C \cap D) = f(C) \cap f(D) \).

### 10.3 BIJECTIVE FUNCTIONS

We have already mentioned, for finite sets \( A \) and \( B \), that if \( f : A \to B \) is a surjective function, then \( |A| \geq |B| \). Also, we mentioned that if \( f : A \to B \) is one-to-one, then \( |A| \leq |B| \). Hence, if \( A \) and \( B \) are finite sets and \( f : A \to B \) is a function that is both one-to-one and onto, then \( |A| = |B| \). What happens when \( A \) and \( B \) are infinite sets will be dealt with in Chapter 11.

A function \( f : A \to B \) is called **bijective** or a **one-to-one correspondence** if it is both one-to-one and onto. From what we mentioned earlier, if a function \( f : A \to B \) is bijective and \( A \) and \( B \) are finite sets, then \( |A| = |B| \). Perhaps it is also clear that if \( A \) and \( B \) are finite sets with \( |A| = |B| \), then there exists a bijective function \( f : A \to B \). A bijective function from a set \( A \) to a set \( B \) creates a pairing of the elements of \( A \) with the elements of \( B \).

In the case where \( A \) and \( B \) are sets with \( |A| = |B| = 3 \), say \( A = \{a, b, c\} \) and \( B = \{x, y, z\} \), the bijective functions from \( A \) to \( B \) are

\[
\begin{align*}
f_1 &= \{(a, x), (b, y), (c, z)\} \\
f_2 &= \{(a, y), (b, z), (c, x)\} \\
f_3 &= \{(a, z), (b, x), (c, y)\} \\
f_4 &= \{(a, y), (b, x), (c, z)\} \\
f_5 &= \{(a, z), (b, y), (c, x)\} \\
f_6 &= \{(a, x), (b, z), (c, y)\}.
\end{align*}
\]

That is, there are six bijective functions from \( A \) to \( B \); indeed there are six bijective functions from any \( 3 \)-element set to any \( 3 \)-element set. More generally, we have the following. (See Exercise 10.34.)
Chapter 10 Functions

Theorem 10.7
If $A$ and $B$ are finite sets with $|A| = |B| = n$, then there are $n!$ bijective functions from $A$ to $B$.

Proof
Suppose that $A = \{a_1, a_2, \ldots, a_n\}$. Then any bijective function $f : A \to B$ can be expressed as

$$f = \{(a_1, -), (a_2, -), \ldots, (a_n, -)\},$$

where the second coordinate of each ordered pair of $f$ belongs to $B$. There are $n$ possible images for $a_1$ in $f$. Once an image for $a_1$ has been determined, then there are $n - 1$ possible images for $a_2$. Since $f$ is one-to-one, no element of $B$ can be the image of two elements of $A$. Because neither of the images of $a_1$ and $a_2$ can be images of $a_3$, there are $n - 2$ possibilities for $a_3$. Continuing in this manner, we see that there is only one possibility for the image of $a_n$. It turns out that the total number of possible bijective functions $f$ is obtained by multiplying these numbers and so there are $n(n - 1)(n - 2) \cdots 1 = n!$ bijective functions from $A$ to $B$.

There is another interesting fact concerning the existence of bijective functions $f : A \to B$ for finite sets $A$ and $B$ with $|A| = |B|$.

Theorem 10.8
Let $A$ and $B$ be finite nonempty sets such that $|A| = |B|$ and let $f$ be a function from $A$ to $B$. Then $f$ is one-to-one if and only if $f$ is onto.

Proof
Let $|A| = |B| = n$. Assume first that $f$ is one-to-one. Since the $n$ elements of $A$ have distinct images, there are $n$ distinct images. Thus, $\text{range}(f) = B$ and so $f$ is onto.

For the converse, assume that $f$ is onto. Thus, each of the $n$ elements of $B$ is an image of some element of $A$. Consequently, the $n$ elements of $A$ have $n$ distinct images in $B$, which implies that no two distinct elements of $A$ can have the same image and so $f$ is one-to-one.

Theorem 10.8 concerns finite sets $A$ and $B$ with $|A| = |B|$. Even though we have not defined cardinality for infinite sets, we would certainly expect that $|A| = |A|$ for every infinite set $A$. With this understanding, Theorem 10.8 is false for infinite sets $A$ and $B$, even when $A = B$. For example, the function $f : \mathbb{Z} \to \mathbb{Z}$ defined by $f(n) = 2n$ is one-to-one; yet its range is the set of all even integers. That is, $f$ is not onto, even though $f$ is a one-to-one function from $\mathbb{Z}$ to $\mathbb{Z}$. The function $f : \mathbb{N} \to \mathbb{N}$ defined by $g(n) = n - 1$ when $n \geq 2$ and $g(1) = 1$ is onto but not one-to-one since $g(1) = g(2) = 1$.

For the sets $A = \{1, 2, 3\}$, $B = \{x, y, z, w\}$ and $C = \{a, b, c\}$ described at the end of Section 10.2, no function from $A$ to $B$ or from $B$ to $C$ can be bijective. It is possible to have a bijective function from $A$ to $C$, however, since $|A| = |C|$. In fact, $g_3$ is such a function, although other bijective functions from $A$ to $C$ exist. Certainly, not every function from $A$ to $C$ is bijective, as $g_4$ illustrates.

For a nonempty set $A$, the function $i_A : A \to A$ defined by $i_A(a) = a$ for each $a \in A$ is called the identity function on $A$. If the set $A$ under discussion is clear, we write the identity function $i_A$ by $i$. For $S = \{1, 2, 3\}$, the identity function is

$$i_S = i = \{(1, 1), (2, 2), (3, 3)\}.$$
Not only is this identity function bijective, the identity function \( i_A \) is bijective for every nonempty set \( A \). Identity functions are important and we will see them again soon.

We give one additional example of a bijective function.

**Result 10.9**  The function \( f : R \rightarrow \{2\} \rightarrow R \rightarrow \{3\} \) defined by

\[
f(x) = \frac{3x}{x-2}
\]

is bijective.

**Proof**

Here it is necessary to show that \( f \) is both one-to-one and onto. We begin with the first of these. Assume that \( f(a) = f(b) \), where \( a, b \in R \rightarrow \{2\} \). Then \( \frac{3a}{a-2} = \frac{3b}{b-2} \). Multiplying both sides by \( (a-2)(b-2) \), we obtain \( 3a(b-2) = 3b(a-2) \). Simplifying, we have \( 3ab - 6a = 3ab - 6b \). Adding \(-3ab\) to both sides and dividing by \(-6\), we obtain \( a = b \). Thus, \( f \) is one-to-one.

To show that \( f \) is onto, let \( r \in R \rightarrow \{3\} \). We show that there exists \( x \in R \rightarrow \{2\} \) such that \( f(x) = r \). Choose \( x = \frac{2r}{r-3} \). Then

\[
f(x) = f \left( \frac{2r}{r-3} \right) = \frac{3 \left( \frac{2r}{r-3} \right)}{\frac{2r}{r-3} - 2} = \frac{6r}{2r - 2(r-3)} = \frac{6r}{6} = r,
\]

implying that \( f \) is onto. Therefore \( f \) is bijective.

**PROOF ANALYSIS**

Some remarks concerning the proof that the function \( f \) in Result 10.9 is onto may be useful. For a given real number \( r \in R \rightarrow \{3\} \), we need to find a real number \( x \in R \rightarrow \{2\} \) such that \( f(x) = r \). Since we wanted \( f(x) = \frac{3x}{x-2} = r \), it was required to solve this equation for \( x \). This can be done by rewriting this equation as \( 3x = r(x-2) \) and then simplifying it to obtain \( rx - 3x = 2r \). Now, factoring \( x \) from \( rx - 3x \) and dividing by \( r - 3 \), we have the desired choice of \( x \), namely \( x = 2r/(r-3) \). Incidentally, it was perfectly permissible to divide by \( r - 3 \) since \( r \in R \rightarrow \{3\} \) and so \( r \neq 3 \). Notice also that \( x \in R \rightarrow \{2\} \) for if \( x = 2r/(r-3) = 2 \), then \( 2r = 2r - 6 \), which is impossible. Although solving \( \frac{3x}{x-2} = r \) for \( x \) is not part of the proof, again it may be useful to include this work in addition to the proof.

Suppose that \( f \) is a function from \( A \) to \( B \), that is, \( f : A \rightarrow B \). If \( f(x) = f(y) \) implies that \( x = y \) for all \( x, y \in A \), then \( f \) is one-to-one. It may seem obvious that if \( x = y \), then \( f(x) = f(y) \) for all \( x, y \in A \) since this is simply a requirement of a function. In order for a relation \( f \) from a set \( A \) to a set \( B \) to be a function from \( A \) to \( B \), the following two conditions must be satisfied:

1. For each element \( a \in A \), there is an element \( b \in B \) such that \( (a, b) \in f \).
2. If \( (a, b), (a, c) \in f \), then \( b = c \).

Condition (1) states that the domain of \( f \) is \( A \), that is, every element of \( A \) has an image in \( B \); while condition (2) says that if an element of \( A \) has an image in \( B \), then this image is unique.
Occasionally, a function \( f \) that satisfies condition (2) is called well-defined. Since (2) is a requirement of every function however, it follows that every function must be well-defined. There are situations, though, when the definition of a function may make it unclear whether \( f \) is well-defined. The next result illustrates this with the set \( \mathbb{Z}_4 \) of integers modulo 4. Recall that \( \mathbb{Z}_4 \) consists of the four classes (sets of integers) \([0],[1],[2],[3] \), where for \( r \in \{0,1,2,3\} \), \([r] = \{3q + r : q \in \mathbb{Z}\} \). Furthermore, if \( a, b \in [r] \) for some \( r \) with \( 0 \leq r \leq 3 \), then \( [a] = [b] \) and \( a \equiv b \mod 4 \).

**Result to Prove**
The function \( f : \mathbb{Z}_4 \rightarrow \mathbb{Z}_4 \) defined by \( f([x]) = [3x + 1] \) is a well-defined bijective function.

**Proof Strategy**
To prove that this function is well-defined, we are required to prove that if \([a] = [b] \), then \( f([a]) = f([b]) \), that is, \([3a + 1] = [3b + 1] \). It seems reasonable to use a direct proof, so we assume that \([a] = [b] \). Since \([a] = [b] \), it follows that \( a \equiv b \mod 4 \). This implies that \( 4 \mid (a - b) \) and so \( a - b = 4k \) for some integer \( k \). To verify that \([3a + 1] = [3b + 1] \), we are required to show that \( 3a + 1 \equiv 3b + 1 \mod 4 \) or, equivalently, that \( (3a + 1) - (3b + 1) = 3a - 3b = 3(a - b) \) is a multiple of 4.

Since \( \mathbb{Z}_4 \) consists only of the four elements \([0],[1],[2],[3] \), to prove that \( f \) is bijective, we need only observe that the elements \( f([0]), f([1]), f([2]), f([3]) \) are distinct by Theorem 10.8.

**Result 10.10**
The function \( f : \mathbb{Z}_4 \rightarrow \mathbb{Z}_4 \) defined by \( f([x]) = [3x + 1] \) is a well-defined bijective function.

**Proof**
First, we verify that this function is well-defined; that is, if \([a] = [b] \), then \( f([a]) = f([b]) \). Assume then that \([a] = [b] \). Thus, \( a \equiv b \mod 4 \) and so \( 4 \mid (a - b) \). Hence, \( a - b = 4k \) for some integer \( k \). Therefore,

\[
(3a + 1) - (3b + 1) = 3(a - b) = 3(4k) = 4(3k).
\]

Since \( 3k \) is an integer, \( 4 \mid [(3a + 1) - (3b + 1)] \). Thus, \( 3a + 1 \equiv 3b + 1 \mod 4 \) and \([3a + 1] = [3b + 1] \); so \( f([a]) = f([b]) \). Hence, \( f \) is well-defined. Since \( f([0]) = [1] \), \( f([1]) = [0] \), \( f([2]) = [3] \) and \( f([3]) = [2] \), it follows that \( f \) is both one-to-one and onto, that is, \( f \) is bijective.

**SECTION 10.3 EXERCISES**

10.30. Prove that the function \( f : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( f(x) = 7x - 2 \) is bijective.

10.31. Let \( f : \mathbb{Z}_5 \rightarrow \mathbb{Z}_5 \) be a function defined by \( f([a]) = [2a + 3] \).

(a) Show that \( f \) is well-defined.

(b) Determine whether \( f \) is bijective.

10.32. Prove that the function \( f : \mathbb{R} \rightarrow \{2\} \rightarrow \mathbb{R} \rightarrow \{5\} \) defined by \( f(x) = \frac{5x + 1}{x - 2} \) is bijective.

10.33. Let \( A = [0,1] \) denote the closed interval of real numbers between 0 and 1. Give an example of two different bijective functions \( f_1 \) and \( f_2 \) from \( A \) to \( A \), neither of which is the identity function.

10.34. Give a proof of Theorem 10.7 using mathematical induction.
10.35. For two finite nonempty sets $A$ and $B$, let $R$ be a relation from $A$ to $B$ such that $\text{range}(R) = B$. Define the domination number $\gamma(R)$ of $R$ as the smallest cardinality of a subset $S \subseteq A$ such that for every element $y$ of $B$, there is an element $x \in S$ such that $x$ is related to $y$.

(a) Let $A = \{1, 2, 3, 4, 5, 6, 7\}$ and $B = \{a, b, c, d, e, f, g\}$ and let $R = \{(1, c), (1, e), (2, c), (2, f), (2, g), (3, b), (3, f), (4, a), (4, c), (4, g), (5, a), (5, b), (5, c), (6, d), (6, e), (7, a), (7, g)\}$. Determine $\gamma(R)$.

(b) If $R$ is an equivalence relation defined on a finite nonempty set $A$ (and so $B = A$), then what is $\gamma(R)$?

(c) If $f$ is a bijective function from $A$ to $B$, then what is $\gamma(f)$?

10.36. Let $A = \{a, b, c, d, e, f\}$ and $B = \{u, v, w, x, y, z\}$. Suppose, with each element $r \in A$, that there is associated a list or subset $L(r) \subseteq B$. The goal is to define a “list function” $\phi : A \to B$ with the property that $\phi(r) \in L(r)$ for each $r \in A$.

(a) For $L(a) = \{w, x, y\}, L(b) = \{u, z\}, L(c) = \{u, v\}, L(d) = \{u, w\}, L(e) = \{u, x, y\}, L(f) = \{v, y\}$, does there exist a bijective list function $\phi : A \to B$ for these lists?

(b) For $L(a) = \{u, v, x, y\}, L(b) = \{v, w, y\}, L(c) = \{v, y\}, L(d) = \{u, w, x, z\}, L(e) = \{v, w\}, L(f) = \{w, y\}$, does there exist a bijective list function $\phi : A \to B$ for these lists?

## 10.4 COMPOSITION OF FUNCTIONS

As it is common to define operations on certain sets of numbers (and on the elements of the set $\mathbb{Z}_n$ of integers modulo $n$, as we described in Chapter 9), it is possible to define operations on certain sets of functions, under suitable circumstances. For example, for functions $f : \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \to \mathbb{R}$, you might recall from calculus that the sum $f + g$ and product $fg$ of $f$ and $g$ are defined by

\[(f + g)(x) = f(x) + g(x) \quad \text{and} \quad (fg)(x) = f(x) \cdot g(x) \tag{10.1}\]

for all $x \in \mathbb{R}$. So if $f$ is defined by $f(x) = x^2$ and $g$ is defined by $g(x) = \sin x$, then $(f + g)(x) = x^2 + \sin x$ and $(fg)(x) = x^2 \sin x$ for all $x \in \mathbb{R}$. In calculus we are especially interested in these operations because once we have learned how to determine the derivatives of $f$ and $g$, we want to know how to use this information to find the derivatives of $f + g$ and $fg$. The derivative of $fg$, for example, gives rise to the well-known product rule for derivatives:

\[(fg)'(x) = f(x) \cdot g'(x) + g(x) \cdot f'(x).\]

This later led us to study the quotient rule for derivatives.

The definitions in (10.1) of the sum $f + g$ and product $fg$ of the functions $f : \mathbb{R} \to \mathbb{R}$ and $g : \mathbb{R} \to \mathbb{R}$ depend on the fact that the codomain of these two functions is $\mathbb{R}$, whose elements can be added and multiplied, and so $f(x) + g(x)$ and $f(x) \cdot g(x)$ make sense. On the other hand, if $f : A \to B$ and $g : A \to B$, where $B = \{a, b, c\}$, say, then $f(x) + g(x)$ and $f(x) \cdot g(x)$ have no meaning.

There is an operation that can be defined on pairs of functions satisfying appropriate conditions that has no connection with numbers. For nonempty sets $A, B$ and $C$ and functions $f : A \to B$ and $g : B \to C$, it is possible to create a new function from $f$ and $g$, called their composition. The composition $g \circ f$ of $f$ and $g$ is the function from $A$ to $C$ defined by

\[(g \circ f)(a) = g(f(a)) \quad \text{for all} \; a \in A.\]
Chapter 10 Functions

To illustrate this definition, let \( A = \{1, 2, 3, 4\} \), \( B = \{a, b, c, d\} \) and \( C = \{r, s, t, u, v\} \) and define the functions \( f : A \to B \) and \( g : B \to C \) by

\[
\begin{align*}
  f &= \{(1, b), (2, d), (3, a), (4, a)\}, \\
  g &= \{(a, u), (b, r), (c, r), (d, s)\}.
\end{align*}
\]

We now have the correct arrangement of sets and functions to consider the composition \( g \circ f \). Since \( g \circ f \) is a function from \( A \) to \( C \), it follows that \( g \circ f \) has the following appearance:

\[
\begin{align*}
  g \circ f &= \{(1, \alpha), (2, \beta), (3, \gamma), (4, \delta)\},
\end{align*}
\]

where \( \alpha, \beta, \gamma, \delta \in C \). It remains only to determine the image of each element of \( A \). First, we find the image of 1. According to the definition of \( g \circ f \),

\[
(g \circ f)(1) = g(f(1)) = g(b) = r,
\]

so \( (1, r) \in g \circ f \). Similarly, \( (g \circ f)(2) = g(f(2)) = g(d) = s \) and \( (2, s) \in g \circ f \). Continuing in this manner, we obtain

\[
\begin{align*}
  g \circ f &= \{(1, r), (2, s), (3, u), (4, u)\}.
\end{align*}
\]

A diagram that illustrates how \( g \circ f \) is determined is shown in Figure 10.2. To find the image of 1 under \( g \circ f \), we follow the arrow from 1 to b and then from b to r. The function \( g \circ f \) is basically found by removing the set \( B \). The fact that \( g \circ f \) is defined does not necessarily imply that \( f \circ g \) is also defined. Since \( g \) is a function from \( B \) to \( C \) and \( f \) is a function from \( A \) to \( B \), the only way that \( f \circ g \) would be defined is if \( \text{range}(g) \subseteq A \). In the example we have just seen, \( f \circ g \) is not defined since \( \text{range}(g) = \{r, s, u\} \not\subseteq A \).

![Figure 10.2 The composition function g ∘ f](image)

Composition of functions was also encountered in calculus. Let’s consider an example of composition that you might have seen in calculus. Again, suppose that the functions \( f : \mathbb{R} \to \mathbb{R} \) and \( g : \mathbb{R} \to \mathbb{R} \) are defined by \( f(x) = x^2 \) and \( g(x) = \sin x \). In this case, we can determine both \( g \circ f \) and \( f \circ g \); namely,

\[
\begin{align*}
  (g \circ f)(x) &= g(f(x)) = g(x^2) = \sin(x^2) \\
  (f \circ g)(x) &= f(g(x)) = f(\sin x) = (\sin x)^2 = \sin^2 x.
\end{align*}
\]
10.4 Composition of Functions

Secondly, this example also serves to illustrate that even when \( g \circ f \) and \( f \circ g \) are both defined, they need not be equal.

The study of composition of functions in calculus led us to the well-known chain rule for differentiation:

\[
(g \circ f)'(x) = g'(f(x)) \cdot f'(x).
\]

There are two facts concerning properties of composition of functions that will be especially useful to us. First, if \( f \) and \( g \) are injective functions such that \( g \circ f \) is defined, then \( g \circ f \) is injective. The corresponding statement is also true for surjective functions.

**Result to Prove**

Let \( f : A \to B \) and \( g : B \to C \) be two functions.

(a) If \( f \) and \( g \) are injective, then so is \( g \circ f \).

(b) If \( f \) and \( g \) are surjective, then so is \( g \circ f \).

**Proof Strategy**

To verify (a), we use a direct proof and begin by assuming that \( f \) and \( g \) are one-to-one.

To show that \( g \circ f \) is one-to-one, we prove that whenever \( (g \circ f)(a_1) = (g \circ f)(a_2) \), then \( a_1 = a_2 \). However, \( (g \circ f)(a_1) = (g \circ f)(a_2) \) means that \( g(f(a_1)) = g(f(a_2)) \). But \( g \) is one-to-one; so \( g(a_1) = g(a_2) \) implies that \( a_1 = a_2 \). This leads us to \( f(a_1) = f(a_2) \). But we also know that \( f \) is one-to-one.

To verify (b), we need to prove that if \( f \) and \( g \) are onto, then \( g \circ f \) is onto. To show that \( g \circ f \) is onto, it is necessary to show that every element of \( C \) is an image of some element of \( A \) under the function \( g \circ f \). So we begin with an element \( c \in C \). Since \( g \) is onto, there is an element \( b \in B \) such that \( g(b) = c \). But \( f \) is onto; so there is an element \( a \in A \) such that \( f(a) = b \). This suggests considering \( (g \circ f)(a) \).

\[\hfill\]

**Theorem 10.11**

Let \( f : A \to B \) and \( g : B \to C \) be two functions.

(a) If \( f \) and \( g \) are injective, then so is \( g \circ f \).

(b) If \( f \) and \( g \) are surjective, then so is \( g \circ f \).

**Proof**

Let \( f : A \to B \) and \( g : B \to C \) be injective functions. Assume that \( (g \circ f)(a_1) = (g \circ f)(a_2) \), where \( a_1, a_2 \in A \). By definition, \( g(f(a_1)) = g(f(a_2)) \). Since \( g \) is injective, it follows that \( f(a_1) = f(a_2) \). However, since \( f \) is injective, it follows that \( a_1 = a_2 \). This implies that \( g \circ f \) is injective.

Next, let \( f : A \to B \) and \( g : B \to C \) be surjective functions and let \( c \in C \). Since \( g \) is surjective, there exists \( b \in B \) such that \( g(b) = c \). On the other hand, since \( f \) is surjective, it follows that there exists \( a \in A \) such that \( f(a) = b \). Hence, \( (g \circ f)(a) = g(f(a)) = g(b) = c \), implying that \( g \circ f \) is also surjective.

Combining the two parts of Theorem 10.11 produces an immediate corollary.

**Corollary 10.12**

If \( f : A \to B \) and \( g : B \to C \) are bijective functions, then \( g \circ f \) is bijective.

For nonempty sets \( A, B, C \) and \( D \), let \( f : A \to B, g : B \to C \) and \( h : C \to D \) be functions. Then the compositions \( g \circ f : A \to C \) and \( h \circ g : B \to D \) are defined, as are the
Chapter 10  Functions

compositions \( h \circ (g \circ f) : A \to D \) and \( (h \circ g) \circ f : A \to D \). Composition of the functions \( f, g \) and \( h \) is associative if the functions \( h \circ (g \circ f) \) and \( (h \circ g) \circ f \) are equal. This is, in fact, the case.

Theorem 10.13  For nonempty sets \( A, B, C \) and \( D \), let \( f : A \to B \), \( g : B \to C \) and \( h : C \to D \) be functions. Then \( (h \circ g) \circ f = h \circ (g \circ f) \).

Proof  Let \( a \in A \) and suppose that \( f(a) = b = g(b) = c \) and \( h(c) = d \). Then
\[
((h \circ g) \circ f)(a) = (h \circ g)(f(a)) = (h \circ g)(b) = h(g(b)) = h(c) = d;
\]
while
\[
(h \circ (g \circ f))(a) = h((g \circ f)(a)) = h(g(f(a))) = h(g(b)) = h(c) = d.
\]
Thus, \( (h \circ g) \circ f = h \circ (g \circ f) \).

As we have mentioned, it is common when considering the composition of functions to begin with two functions \( f \) and \( g \), where \( f : A \to B \) and \( g : B \to C \) and arrive at the function \( g \circ f : A \to C \). Strictly speaking, however, all that is needed is for the domain of \( g \) to be a set \( B' \) where \( \text{range}(f) \) is a subset of \( B' \). In other words, if \( f \) and \( g \) are functions with \( f : A \to B \) and \( g : B' \to C \), where \( \text{range}(f) \subseteq B' \), then the composition \( g \circ f : A \to C \) is defined.

Example 10.14  For the sets \( A = \{-3, -2, \ldots, 3\} \) and \( B = \{0, 1, \ldots, 10\} \), \( B' = \{0, 1, 4, 5, 8, 9\} \) and \( C = \{1, 2, \ldots, 10\} \), let \( f : A \to B \) and \( g : B' \to C \) be functions defined by \( f(n) = n^2 \) for all \( n \in A \) and \( g(n) = n + 1 \) for all \( n \in B' \).

\( a \)  Show that the composition \( g \circ f : A \to C \) is defined.

\( b \)  For \( n \in A \), determine \( (g \circ f)(n) \).

Solution  \( a \)  Since \( \text{range}(f) = \{0, 1, 4, 9\} \) and \( \text{range}(f) \subseteq B' \), it follows that the composition \( g \circ f : A \to C \) is defined.

\( b \)  For \( n \in A \), \( (g \circ f)(n) = g(f(n)) = g(n^2) = n^2 + 1 \).

SECTION 10.4 EXERCISES

10.37. Let \( A = \{1, 2, 3, 4\} \), \( B = \{a, b, c\} \) and \( C = \{w, x, y, z\} \). Consider the functions \( f : A \to B \) and \( g : B \to C \), where \( f = \{(1, b), (2, c), (3, c), (4, a)\} \) and \( g = \{(a, x), (b, y), (c, x)\} \). Determine \( g \circ f \).

10.38. Two functions \( f : R \to R \) and \( g : R \to R \) are defined by \( f(x) = 3x^2 + 1 \) and \( g(x) = 5x - 3 \) for all \( x \in R \). Determine \( (g \circ f)(1) \) and \( (f \circ g)(1) \).

10.39. Two functions \( f : Z_{10} \to Z_{10} \) and \( g : Z_{10} \to Z_{10} \) are defined by \( f([a]) = [3a] \) and \( g([a]) = [7a] \).

\( a \)  Determine \( g \circ f \) and \( f \circ g \).

\( b \)  What can be concluded as a result of (a)?

10.40. Let \( A \) and \( B \) be nonempty sets. Prove that if \( f : A \to B \), then \( f \circ i_A = f \) and \( i_B \circ f = f \).

10.41. Let \( A \) be a nonempty set and let \( f : A \to A \) be a function. Prove that if \( f \circ f = i_A \), then \( f \) is bijective.
10.42. Prove or disprove the following:

(a) If two functions \( f : A \to B \) and \( g : B \to C \) are both bijective, then \( g \circ f : A \to C \) is bijective.
(b) Let \( f : A \to B \) and \( g : B \to C \) be two functions. If \( g \) is onto, then \( g \circ f : A \to C \) is onto.
(c) Let \( f : A \to B \) and \( g : B \to C \) be two functions. If \( g \) is one-to-one, then \( g \circ f : A \to C \) is one-to-one.
(d) There exist functions \( f : A \to B \) and \( g : B \to C \) such that \( f \) is not onto and \( g \circ f : A \to C \) is onto.
(e) There exist functions \( f : A \to B \) and \( g : B \to C \) such that \( f \) is not one-to-one and \( g \circ f : A \to C \) is one-to-one.

10.43. For nonempty sets \( A, B \) and \( C \), let \( f : A \to B \) and \( g : B \to C \) be functions.

(a) Prove:

If \( g \circ f \) is one-to-one, then \( f \) is one-to-one.

using each of the following proof techniques: direct proof, proof by contrapositive, proof by contradiction.

(b) Disprove: If \( g \circ f \) is one-to-one, then \( g \) is one-to-one.

10.44. Let \( A \) denote the set of integers that are multiples of 4, let \( B \) denote the set of integers that are multiples of 8 and let \( B' \) denote the set of even integers. Thus, \( A = \{4k : k \in \mathbb{Z}\} \), \( B = \{8k : k \in \mathbb{Z}\} \) and \( B' = \{2k : k \in \mathbb{Z}\} \). Let \( f : A \times A \to B \) and \( g : B' \to Z \) be functions defined by \( f((x, y)) = xy \) for \( x, y \in A \) and \( g(n) = n/2 \) for \( n \in B' \). For simplicity, we denote \( f((x, y)) \) by \( f(x, y) \). So \( f(x, y) = xy \).

(a) Show that the composition function \( g \circ f : A \times A \to Z \) is defined.
(b) For \( k, \ell \in \mathbb{Z} \), determine \( (g \circ f)(4k, 4\ell) \).

10.45. Let \( A \) be the set of even integers and \( B \) the set of odd integers. A function \( f : A \times B \to B \times A \) is defined by \( f(a, b) = (a + b, a) \) and a function \( g : B \times A \to B \times B \) is defined by \( g(c, d) = (c + d, c) \).

(a) Determine \( (g \circ f)(18, 11) \).
(b) Determine whether the function \( g \circ f : A \times B \to B \times B \) is one-to-one.
(c) Determine whether \( g \circ f \) is onto.

10.46. Let \( A \) be the set of odd integers and \( B \) the set of even integers. A function \( f : A \times B \to A \times A \) is defined by \( f(a, b) = (3a - b, a + b) \) and a function \( g : A \times A \to B \times A \) is defined by \( g(c, d) = (c - d, 2c + d) \).

(a) Determine \( (g \circ f)(3, 8) \).
(b) Determine whether the function \( g \circ f : A \times B \to B \times A \) is one-to-one.
(c) Determine whether \( g \circ f \) is onto.

10.47. For functions \( f, g \) and \( h \) with domain and codomain \( \mathbb{R} \), prove or disprove the following:

(a) \((g + h) \circ f = (g \circ f) + (h \circ f)\).
(b) \(f \circ (g + h) = (f \circ g) + (f \circ h)\).

10.48. The composition \( g \circ f : (0, 1) \to \mathbb{R} \) of two functions \( f \) and \( g \) is given by \((g \circ f)(x) = \frac{4x-1}{2\sqrt{x-x^2}}\), where \( f : (0, 1) \to (-1, 1) \) is defined by \( f(x) = 2x - 1 \) for \( x \in (0, 1) \). Determine the function \( g \).

10.5 INVERSE FUNCTIONS

Associated with every bijective function is another bijective function. In order to describe this second bijective function, we return to relations to recall a concept introduced in Chapter 9. For a relation \( R \) from a set \( A \) to a set \( B \), the inverse relation \( R^{-1} \) from \( B \) to \( A \)
Chapter 10 Functions

is defined as

\[ R^{-1} = \{(b, a) : (a, b) \in R\}. \]

For example, if \( A = \{a, b, c, d\} \), \( B = \{1, 2, 3\} \) and

\[ R = \{(a, 1), (a, 3), (c, 2), (c, 3), (d, 1)\} \]

is a relation from \( A \) to \( B \), then

\[ R^{-1} = \{(1, a), (3, a), (2, c), (3, c), (1, d)\} \]

is the inverse relation of \( R \). Of course, every function \( f : A \to B \) is also a relation from \( A \) to \( B \) and so there is an inverse relation \( f^{-1} \) from \( B \) to \( A \). This brings up a natural question:

Under what conditions is the inverse relation \( f^{-1} \) from \( B \) to \( A \) also a function from \( B \) to \( A \)? If the inverse relation \( f^{-1} \) is a function from \( B \) to \( A \), then certainly \( \text{dom}(f^{-1}) = B \).

This means that \( f \) must be onto. If \( f \) is not one-to-one, then \( f(a_1) = f(a_2) = b \) for some \( a_1, a_2 \in A \) and \( b \in B \), where \( a_1 \neq a_2 \). But then \((b, a_1), (b, a_2) \in f^{-1}\), which cannot occur if \( f^{-1} \) is a function. Consequently, if \( f^{-1} \) is a function from \( B \) to \( A \), then \( f \) must be one-to-one. This leads us to the following theorem. In the proof, two basic facts are used repeatedly, namely

1. \( f(a) = b \) if and only if \((a, b) \in f\)
2. If \( f^{-1} \) is a function and \( f(a) = b \), then \((b, a) \in f^{-1}\).

**Theorem 10.15** Let \( f : A \to B \) be a function. Then the inverse relation \( f^{-1} \) is a function from \( B \) to \( A \) if and only if \( f \) is bijective. Furthermore, if \( f \) is bijective, then \( f^{-1} \) is also bijective.

**Proof** First, assume that \( f^{-1} \) is a function from \( B \) to \( A \). We show that \( f \) is both one-to-one and onto. Assume that \( f(a_1) = f(a_2) = y \), where \( y \in B \). Then \((a_1, y), (a_2, y) \in f\), implying that \((y, a_1), (y, a_2) \in f^{-1}\). Since \( f^{-1} \) is a function from \( B \) to \( A \), every element of \( B \) has a unique image under \( f^{-1}\). Thus, in particular, \( y \) has a unique image under \( f^{-1}\). Since \( f^{-1}(y) = a_1 \) and \( f^{-1}(y) = a_2 \), it now follows that \( a_1 = a_2 \) and so \( f \) is one-to-one.

To show that \( f \) is onto, let \( b \in B \). Since \( f^{-1} \) is a function from \( B \) to \( A \), there exists a unique element \( a \in A \) such that \( f^{-1}(b) = a \). Hence, \((b, a) \in f^{-1}\), implying that \((a, b) \in f\), that is, \( f(a) = b \). Therefore, \( f \) is onto and so \( f \) is bijective.

For the converse, assume that the function \( f : A \to B \) is bijective. We show that \( f^{-1} \) is a function from \( B \) to \( A \). Let \( b \in B \). Since \( f \) is onto, there exists \( a \in A \) such that \((a, b) \in f\). Hence, \((b, a) \in f^{-1}\). It remains to show that \((b, a) \in f^{-1}\) whose first coordinate is \( b \). Assume that \((b, a) \) and \((b, a') \) are both in \( f^{-1}\). Then \((a, b), (a', b) \in f\), which implies that \( f(a) = f(a') = b \). Since \( f \) is one-to-one, \( a = a' \). Therefore, we have shown that for every \( b \in B \), there exists a unique element \( a \in A \) such that \((b, a) \in f^{-1}\), that is, \( f^{-1} \) is a function from \( B \) to \( A \).

Finally, we show that if \( f \) is bijective, then \( f^{-1} \) is bijective. Assume that \( f \) is bijective. We have just seen that \( f^{-1} \) is a function from \( B \) to \( A \). First, we show that \( f^{-1} \) is one-to-one.

Assume that \( f^{-1}(b_1) = f^{-1}(b_2) = a \). Then \((b_1, a), (b_2, a) \in f^{-1}\) and so \((a, b_1), (a, b_2) \in f\). Since \( f \) is a function, \( b_1 = b_2 \) and \( f^{-1} \) is one-to-one. To show that \( f^{-1} \) is onto, let \( a \in A \). Since \( f \) is a function, there is an element \( b \in B \) such that \((a, b) \in f\). Consequently, \((b, a) \in f^{-1}\) so that \( f^{-1}(b) = a \) and \( f^{-1} \) is onto. Therefore, \( f^{-1} \) is bijective.
According to Theorem 10.15, if \( f : A \to B \) is a bijective function, then \( f^{-1} : B \to A \) is also a bijective function. The function \( f^{-1} \) is referred to as the inverse function or simply the inverse of \( f \). Hence, both composition functions \( f^{-1} \circ f \) and \( f \circ f^{-1} \) are defined. In fact, \( f^{-1} \circ f \) is a function from \( A \) to \( A \) and \( f \circ f^{-1} \) is a function from \( B \) to \( B \). As we are about to learn, \( f^{-1} \circ f \) and \( f \circ f^{-1} \) are functions we’ve visited earlier. Let \( a \in A \) and suppose that \( f(a) = b \). So, \((a, b) \in f \) and therefore \((b, a) \in f^{-1} \), that is, \( f^{-1}(b) = a \). Thus, 
\[
(f^{-1} \circ f)(a) = f^{-1}(f(a)) = f^{-1}(b) = a \quad \text{and} \quad (f \circ f^{-1})(b) = f(f^{-1}(b)) = f(a) = b.
\]
So, it follows that 
\[
f^{-1} \circ f = i_A \quad \text{and} \quad f \circ f^{-1} = i_B
\]
are the identity functions on the sets \( A \) and \( B \), respectively (see Figure 10.3).

![Figure 10.3 A bijective function and its inverse](image.png)

In fact, if \( f : A \to B \) and \( g : B \to A \) are functions for which \( g \circ f = i_A \) and \( f \circ g = i_B \), then \( f \) and \( g \) have some important properties.

**Theorem 10.16**  
If \( f : A \to B \) and \( g : B \to A \) are two functions such that \( g \circ f = i_A \) and \( f \circ g = i_B \), then \( f \) and \( g \) are bijective and \( g = f^{-1} \).

**Proof**  
Let \( f : A \to B \) and \( g : B \to A \) be two functions such that \( g \circ f = i_A \) and \( f \circ g = i_B \).  
First, we show that \( f \) is one-to-one. Assume that \( f(a_1) = f(a_2) \), where \( a_1, a_2 \in A \). Then 
\[
g(f(a_1)) = g(f(a_2))
\]
Since \( g \circ f = i_A \), it follows that 
\[
a_1 = (g \circ f)(a_1) = g(f(a_1)) = g(f(a_2)) = (g \circ f)(a_2) = a_2
\]
and so \( f \) is one-to-one.  
Next, we show that \( f \) is onto. Let \( b \in B \) and suppose that \( g(b) = a \). Since \( f \circ g = i_B \), it follows that \( (f \circ g)(b) = b \). Therefore, \( f(g(b)) = f(a) = b \) and so \( f \) is onto. Hence, \( f \) is bijective and, by Theorem 10.15, \( f^{-1} \) exists. Similarly, \( g \) is bijective.  

It remains to show that \( g = f^{-1} \). Let \( b \) be an arbitrary element of \( B \). We show that \( g(b) = f^{-1}(b) \). Since \( f \) is onto, there exists \( a \in A \) such that \( f(a) = b \) in \( B \). Then 
\[
f^{-1}(b) = a
\]
Since \( g \circ f = i_A \), it follows that \( a = (g \circ f)(a) = g(f(a)) = g(b) \). Therefore, \( g(b) = f^{-1}(b) \) and so \( g = f^{-1} \).

If a bijective function \( f \) has a relatively small number of ordered pairs, then it is easy to find \( f^{-1} \). But what if \( f \) is a bijective function that one might encounter in calculus, say? We illustrate this next with a function described in Result 10.9.
Chapter 10  Functions

Example 10.17  The function \( f : \mathbb{R} - \{2\} \rightarrow \mathbb{R} - \{3\} \) defined by

\[
 f(x) = \frac{3x}{x-2}
\]

is known to be bijective. Determine \( f^{-1}(x) \), where \( x \in \mathbb{R} - \{3\} \).

Solution  Since \((f \circ f^{-1})(x) = x\) for all \( x \in \mathbb{R} - \{3\} \), it follows that

\[
(f \circ f^{-1})(x) = f(f^{-1}(x)) = \frac{3f^{-1}(x)}{f^{-1}(x) - 2} = x.
\]

Thus, \( 3f^{-1}(x) = xf^{-1}(x) - 2 \) and \( 3f^{-1}(x) = xf^{-1}(x) - 2x \). Collecting the terms involving \( f^{-1}(x) \) on the same side of the equation and then factoring out the term \( f^{-1}(x) \), we have

\[
 xf^{-1}(x) - 3f^{-1}(x) = 2x;
\]

so

\[
 f^{-1}(x)(x - 3) = 2x.
\]

Solving for \( f^{-1}(x) \), we obtain

\[
 f^{-1}(x) = \frac{2x}{x - 3}.
\]

Analysis  You might very well have dealt with the problem of finding the inverse of a function before and might recall a somewhat different approach than the one we just gave. Let’s look at this example again, but from a different perspective.

When we consider functions from calculus, rather than writing \( f(x) = x^2 \), \( g(x) = 5x + 1 \) or \( h(x) = x + \frac{1}{x} \), we sometimes write these as \( y = x^2 \), \( y = 5x + 1 \) or \( y = x + \frac{1}{x} \).

In Example 10.17, we were given \( f(x) = \frac{3x}{x-2} \) and found that \( f^{-1}(x) = \frac{2x}{x - 3} \). Let’s write the inverse as \( y = \frac{2x}{x - 3} \) instead. That is, \((x, y) \in f^{-1} \), where \( y = \frac{2x}{x - 3} \). Of course, initially, we don’t know what \( y \) is. But if \((x, y) \in f^{-1}\), then \((y, x) \in f\) and we know that \( x = f(y) = \frac{3y}{y - 2} \). Solving this equation for \( y \), we have \( x(y - 2) = 3y \), so \( xy - 2x = 3y \). Collecting the terms with \( y \) on the same side of the equation and factoring out the term \( y \), we obtain

\[
 xy - 3y = 2x \quad \text{and} \quad y(x - 3) = 2x.
\]

Solving for \( y \), we obtain \( y = \frac{2x}{x - 3} \); that is,

\[
 f^{-1}(x) = \frac{2x}{x - 3}.
\]

In short, to find \( f^{-1} \) if \( f(x) = \frac{3x}{x - 2} \), we replace \( f(x) \) by \( x \) and \( x \) by \( y \) and then solve for \( y \). The result is \( f^{-1}(x) \). Of course, the procedure we have described for finding \( f^{-1}(x) \)
is exactly the same as before. The only difference is the notation. You might have also noticed that the algebra performed to determine \( f^{-1}(x) \) in Example 10.17 is exactly the same as the algebra performed in proving \( f \) is onto in Result 10.9.

The following two examples also deal with finding the inverses of bijective functions. In the first example, we use the fact that every real number has a unique cube root and in the second example, every nonnegative real number has a unique square root (which is also nonnegative).

**Example 10.18** Let \( f : \mathbb{R} \to \mathbb{R} \) be defined by \( f(x) = \frac{x^3 + 1}{2} \).

(a) Prove that \( f \) is bijective.

(b) Determine \( f^{-1}(x) \).

(a) **Proof** First, we show that \( f \) is one-to-one. Assume that \( f(a) = f(b) \), where \( a, b \in \mathbb{R} \). Then \( \frac{a^3 + 1}{2} = \frac{b^3 + 1}{2} \) and so \( a^3 = b^3 \). Taking the cube roots of both sides, we have \( a = b \) and so \( f \) is one-to-one.

Next, we show that \( f \) is onto. Let \( r \in \mathbb{R} \). We show that there exists \( x \in \mathbb{R} \) such that \( f(x) = r \). Let \( x = \sqrt[3]{2r - 1} \in \mathbb{R} \). Then

\[
f(x) = f\left(\sqrt[3]{2r - 1}\right) = \frac{\left(\sqrt[3]{2r - 1}\right)^3 + 1}{2} = \frac{(2r - 1) + 1}{2} = r.
\]

Hence, \( f \) is onto and, consequently, \( f \) is bijective.

(b) **Solution** Since \((f \circ f^{-1})(x) = x\) for all \( x \in \mathbb{R} \), it follows that

\[
(f \circ f^{-1})(x) = f\left(f^{-1}(x)\right) = \frac{(f^{-1}(x))^3 + 1}{2} = x.
\]

Thus, \((f^{-1}(x))^3 = 2x - 1\) and so \(f^{-1}(x) = \sqrt[3]{2x - 1}\).

**Example 10.19** Let \( f : [0, 1] \to [0, 1] \) be defined by \( f(x) = \sqrt{1 - x^2} \).

(a) Prove that \( f \) is bijective.

(b) Determine \( f^{-1}(x) \).

(a) **Proof** First, we show that \( f \) is one-to-one. Assume that \( f(a) = f(b) \), where \( a, b \in [0, 1] \). Then \( \sqrt{1 - a^2} = \sqrt{1 - b^2} \). Squaring both sides, we obtain \( 1 - a^2 = 1 - b^2 \) and so \( a^2 = b^2 \). Since \( a \geq 0 \) and \( b \geq 0 \), it follows that \( a = b \). Hence, \( f \) is one-to-one.

Next, we show that \( f \) is onto. Let \( r \in [0, 1] \). We show that there exists \( x \in [0, 1] \) such that \( f(x) = r \). Let \( x = \sqrt{1 - r^2} \in [0, 1] \). Then

\[
f(x) = f\left(\sqrt{1 - r^2}\right) = \sqrt{1 - \left(\sqrt{1 - r^2}\right)^2} = \sqrt{1 - (1 - r^2)} = \sqrt{r^2}.
\]

Since \( r \geq 0 \), it follows that \( f(x) = r \) and so \( f \) is onto. Thus, \( f \) is bijective.
(b) **Solution** Since \((f \circ f^{-1})(x) = x\) for all \(x \in [0, 1]\), it follows that

\[
(f \circ f^{-1})(x) = f(f^{-1}(x)) = \sqrt{1 - (f^{-1}(x))^2} = x.
\]

Hence, \(1 - (f^{-1}(x))^2 = x^2\) and so \((f^{-1}(x))^2 = 1 - x^2\). Since \(f^{-1}(x) \in [0, 1]\), it follows that \(f^{-1}(x) = \sqrt{1 - x^2}\).

Finding the inverse of a bijective function is not always possible by algebraic manipulation. For example, the function \(f : \mathbb{R} \to (0, \infty)\) defined by \(f(x) = e^x\) is bijective but \(f^{-1}(x) = \ln x\). Indeed, the function \(g : \mathbb{R} \to \mathbb{R}\) defined by \(g(x) = 3x^3 + 5x^3 + 4x - 1\) is bijective but there is no way to find an expression for \(g^{-1}(x)\).

If \(f : A \to B\) is a one-to-one function from \(A\) to \(B\) that is not onto, then, of course, \(f\) is not bijective, and, according to Theorem 10.15, \(f\) does not have an inverse (from \(B\) to \(A\)). On the other hand, if we define a new function \(g : A \to \text{range}(f)\) by \(g(x) = f(x)\) for all \(x \in A\), then \(g\) is a bijection and so its inverse function \(g^{-1} : \text{range}(f) \to A\) exists. For example, let \(E\) denote the set of all even integers and consider the function \(f : \mathbb{Z} \to \mathbb{Z}\) by \(f(n) = 2n\). Then this function \(f\) is injective but not surjective and so there is no inverse function of \(f\) from \(\mathbb{Z}\) to \(\mathbb{Z}\). Observe that \(\text{range}(f) = E\). If we define \(g : \mathbb{Z} \to E\) by \(g(n) = f(n)\) for all \(n \in \mathbb{Z}\), then \(g\) is injective and so \(g^{-1} : E \to \mathbb{Z}\) is a (bijection) function. In fact, \(g^{-1}(n) = n/2\) for all \(n \in E\).

There is a class of bijective functions in which we often have a specific interest. We conclude this chapter with a brief discussion of these functions. We have already mentioned that the identity function \(i_A\) defined on a nonempty set \(A\) is bijective. Normally, there are many bijective functions that can be defined on nonempty sets. Indeed, the number of bijections on an \(n\)-element set is \(n!\), according to Theorem 10.7. These types of functions occur often in mathematics, especially in the area of mathematics called abstract (or modern) algebra.

A **permutation** of (or on) a nonempty set \(A\) is a bijective function on \(A\), that is, a function from \(A\) to \(A\) that is both one-to-one and onto. By Results 10.4 and 10.6, the function \(f : \mathbb{R} \to \mathbb{R}\) defined by \(f(x) = 3x - 5\) is a permutation of \(\mathbb{R}\). Let’s consider an even simpler example. For \(A = \{1, 2, 3\}\), let \(f\) be a permutation of \(A\). Then \(f\) is completely determined once we know the images of 1, 2 and 3 under \(f\). We saw that there are three possible choices for \(f(1)\), two choices for \(f(2)\) once \(f(1)\) has been specified, and one choice for \(f(3)\) once \(f(1)\) and \(f(2)\) have been specified. From this, it follows that there are \(3 \cdot 2 \cdot 1 = 6\) different permutations \(f\) of the set \(A = \{1, 2, 3\}\). This agrees with Theorem 10.7.

One of these functions is the identity function defined on \(\{1, 2, 3\}\), which we denote by \(\alpha_1\); that is,

\[
\alpha_1 = \{(1, 1), (2, 2), (3, 3)\}.
\]

Another permutation of \(\{1, 2, 3\}\) is

\[
\alpha_2 = \{(1, 1), (2, 3), (3, 2)\}.
\]

There are other common ways to represent these permutations. A permutation of \(\{1, 2, 3\}\) is also written as

\[
\begin{pmatrix}
1 & 2 & 3 \\
\end{pmatrix}
\]
where the numbers immediately below 1, 2 and 3 are their images. Hence, $\alpha_1$, $\alpha_2$ and
the other four permutations of $\{1, 2, 3\}$ can be expressed as:

$$
\alpha_1 = \begin{pmatrix}
1 & 2 & 3 \\
1 & 2 & 3
\end{pmatrix},
\alpha_2 = \begin{pmatrix}
1 & 2 & 3 \\
1 & 3 & 2
\end{pmatrix},
\alpha_3 = \begin{pmatrix}
1 & 2 & 3 \\
3 & 2 & 1
\end{pmatrix},
\alpha_4 = \begin{pmatrix}
1 & 2 & 3 \\
2 & 1 & 3
\end{pmatrix},
\alpha_5 = \begin{pmatrix}
1 & 2 & 3 \\
2 & 3 & 1
\end{pmatrix},
\alpha_6 = \begin{pmatrix}
1 & 2 & 3 \\
3 & 1 & 2
\end{pmatrix}.
$$

Since each permutation $\alpha_i$ ($1 \leq i \leq 6$) is a bijective function from $\{1, 2, 3\}$ to $\{1, 2, 3\}$, it follows from Corollary 10.12 that the composition of any two permutations of $\{1, 2, 3\}$ is again a permutation of $\{1, 2, 3\}$. For example, let’s consider

$$
\alpha_2 \circ \alpha_5 = \begin{pmatrix}
1 & 2 & 3 \\
1 & 3 & 2
\end{pmatrix} \circ \begin{pmatrix}
1 & 2 & 3 \\
2 & 3 & 1
\end{pmatrix} = \begin{pmatrix}
1 & 2 & 3 \\
3 & 2 & 1
\end{pmatrix} = \alpha_3.
$$

By Theorem 10.13, it follows that composition of permutations on the same nonempty set $A$ is associative. Hence, for all integers $i, j, k \in\{1, 2, \cdot \cdot \cdot, 6\}$,

$$(\alpha_i \circ \alpha_j) \circ \alpha_k = \alpha_i \circ (\alpha_j \circ \alpha_k).$$

Also, by Theorem 10.15, since a permutation is a bijective function, each permutation has an inverse, which is also a permutation. Thus, for each $i$ ($1 \leq i \leq 6$), $\alpha_i^{-1} = \alpha_j$ for some $j$ ($1 \leq j \leq 6$). The inverse of a permutation can be found by interchanging the two rows and then re-ordering the columns so that the top row is in the natural order 1, 2, 3, … . Thus,

$$
\alpha_5^{-1} = \begin{pmatrix}
2 & 3 & 1 \\
1 & 2 & 3
\end{pmatrix} = \begin{pmatrix}
1 & 2 & 3 \\
3 & 1 & 2
\end{pmatrix} = \alpha_6.
$$

The set of all $n!$ permutations of the set $\{1, 2, \cdot \cdot \cdot, n\}$ is denoted by $S_n$. Thus,

$$S_3 = \{\alpha_1, \alpha_2, \cdot \cdot \cdot, \alpha_6\}.$$

As we have seen with $S_3$, the elements of $S_n$ satisfy the properties of closure, associativity and the existence of inverses for every positive integer $n$. This will be revisited in Chapter 15.

**SECTION 10.5 EXERCISES**

10.49. Let $A = \{a, b, c\}$. Give an example of a function $f : A \rightarrow A$ such that the inverse (relation) $f^{-1}$ is not a function.

10.50. Show that the function $f : R \rightarrow R$ defined by $f(x) = 4x - 3$ is bijective and determine $f^{-1}(x)$ for $x \in R$.

10.51. Show that the function $f : R - \{3\} \rightarrow R - \{5\}$ defined by $f(x) = \frac{5x}{x - 3}$ is bijective and determine $f^{-1}(x)$ for $x \in R - \{5\}$.
Chapter 10

10.52. The functions \( f : \mathbb{R} \to \mathbb{R} \) and \( g : \mathbb{R} \to \mathbb{R} \) defined by \( f(x) = 2x + 1 \) and \( g(x) = 3x - 5 \) for \( x \in \mathbb{R} \) are bijective. Determine the inverse function of \( g \circ f^{-1} \).

10.53. Let \( A \) and \( B \) be sets with \( |A| = |B| = 3 \). How many functions from \( A \) to \( B \) have inverse functions?

10.54. Let the functions \( f : \mathbb{R} \to \mathbb{R} \) and \( g : \mathbb{R} \to \mathbb{R} \) be defined by \( f(x) = 2x + 3 \) and \( g(x) = -3x + 5 \).

(a) Show that \( f \) is one-to-one and onto.
(b) Show that \( g \) is one-to-one and onto.
(c) Determine the composition function \( g \circ f \).
(d) Determine the inverse functions \( f^{-1} \) and \( g^{-1} \).
(e) Determine the inverse function \( (g \circ f)^{-1} \) of \( g \circ f \) and the composition \( f^{-1} \circ g^{-1} \).

10.55. Let \( A = \mathbb{R} - \{1\} \) and define \( f : A \to A \) by \( f(x) = \frac{x}{x-1} \) for all \( x \in A \).

(a) Prove that \( f \) is bijective.
(b) Determine \( f^{-1} \).
(c) Determine \( f \circ f \).

10.56. Let \( A, B \) and \( C \) be nonempty sets and let \( f, g \) and \( h \) be functions such that \( f : A \to B \), \( g : B \to C \) and \( h : B \to C \). Show or disprove:

(a) If \( g \circ f = h \circ f \), then \( g = h \).
(b) If \( f \) is one-to-one and \( g \circ f = h \circ f \), then \( g = h \).

10.57. The function \( f : \mathbb{R} \to \mathbb{R} \) is defined by \( f(x) = \begin{cases} \frac{1}{1-x} & \text{if } x < 1 \\ \sqrt{x} - 1 & \text{if } x \geq 1 \end{cases} \).

(a) Show that \( f \) is a bijection.
(b) Determine the inverse \( f^{-1} \) of \( f \).

10.58. Suppose, for a function \( f : A \to B \), that there is a function \( g : B \to A \) such that \( f \circ g = i_B \). Prove that if \( g \) is surjective, then \( g \circ f = i_A \).

10.59. Let \( f : A \to B \), \( g : B \to C \) and \( h : B \to C \) be functions where \( f \) is a bijection. Prove that if \( g \circ f = h \circ f \), then \( g = h \).

10.60. Let \( \alpha = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 3 & 4 & 5 & 1 \end{pmatrix} \) and \( \beta = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 5 & 2 & 4 & 1 \end{pmatrix} \) be permutations in \( S_5 \). Determine \( \alpha \circ \beta \) and \( \beta^{-1} \).

10.61. Let \( \alpha = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 2 & 6 & 4 & 1 & 5 & 3 \end{pmatrix} \) and \( \beta = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 5 & 3 & 6 & 2 & 1 & 4 \end{pmatrix} \) be elements of \( S_6 \).

(a) Determine \( \alpha^{-1} \) and \( \beta^{-1} \).
(b) Determine \( \alpha \circ \beta \) and \( \beta \circ \alpha \).

10.62. Prove for every integer \( n \geq 3 \) that there exist \( \alpha, \beta \in S_n \) for which \( \alpha \circ \beta \neq \beta \circ \alpha \).

Chapter 10 Supplemental Exercises

10.63. Let \( f : \mathbb{R} \to \mathbb{R} \) be the function defined by \( f(x) = x^2 + 3x + 4 \).

(a) Show that \( f \) is not injective.
(b) Find all pairs \( r_1, r_2 \) of real numbers such that \( f(r_1) = f(r_2) \).
(c) Show that \( f \) is not surjective.
Chapter 10 Supplemental Exercises

(d) Find the set \( S \) of all real numbers such that if \( s \in S \), then there is no real number \( x \) such that \( f(x) = s \).

(e) What well-known set is the set \( S \) in (d) related to?

10.64. Let \( f : \mathbb{R} \rightarrow \mathbb{R} \) be the function defined by \( f(x) = x^2 + ax + b \), where \( a, b \in \mathbb{R} \).
Show that \( f \) is not one-to-one. [Hint: It might be useful to consider the cases \( a \neq 0 \) and \( a = 0 \) separately.]

10.65. In Result 10.4, we saw that the (linear) function \( f : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( f(x) = 3x - 5 \) is one-to-one. In fact, we have seen other linear functions that are one-to-one. Prove the following generalization of this result: The function \( f : \mathbb{R} \rightarrow \mathbb{R} \) defined by \( f(x) = ax + b \), where \( a, b \in \mathbb{R} \) and \( a \neq 0 \), is one-to-one.

10.66. Evaluate the proposed proof of the following result.

**Result**  The function \( f : \mathbb{R} - \{1\} \rightarrow \mathbb{R} - \{3\} \) defined by \( f(x) = \frac{3x}{x-1} \) is bijective.

**Proof**  First, we show that \( f \) is one-to-one. Assume that \( f(a) = f(b) \), where \( a, b \in \mathbb{R} - \{1\} \). Then \( \frac{3a}{a-1} = \frac{3b}{b-1} \). Crossmultiplying, we obtain \( 3a(b-1) = 3b(a-1) \). Simplifying, we have \( 3ab - 3a = 3ab - 3b \). Subtracting \( 3ab \) from both sides and dividing by \(-3\), we have \( a = b \). Thus, \( f \) is one-to-one.

Next, we show that \( f \) is onto. Let \( f(x) = r \). Then \( \frac{3x}{x-1} = r \); so \( 3x = r(x-1) \). Simplifying, we have \( 3x = rx - r \) and so \( 3x - rx = -r \). Therefore, \( x(3-r) = -r \).
Since \( r \in \mathbb{R} - \{3\} \), we can divide by \( 3 - r \) and obtain \( x = -\frac{r}{r-3} = \frac{r}{r-3} \).
Therefore,
\[
f(x) = f \left( \frac{r}{r-3} \right) = \frac{3 \left( \frac{r}{r-3} \right)}{ \frac{r}{r-3} - 1} = \frac{3r}{r-(r-3)} = \frac{3r}{3} = r.
\]
Thus, \( f \) is onto.

10.67. For each of the following functions, determine, with explanation, whether the function is one-to-one and whether it is onto.

(a) \( f : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R} \times \mathbb{R} \), where \( f(x, y) = (3x - 2, 5y + 7) \)
(b) \( g : \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{Z} \times \mathbb{Z} \), where \( g(m, n) = (n + 6, 2 - m) \)
(c) \( h : \mathbb{Z} \times \mathbb{Z} \rightarrow \mathbb{Z} \times \mathbb{Z} \), where \( h(r, s) = (2r + 1, 4s + 3) \)
(d) \( \phi : \mathbb{Z} \times \mathbb{Z} \rightarrow S = \{ a + b\sqrt{2} : a, b \in \mathbb{Z} \} \), where \( \phi(a, b) = a + b\sqrt{2} \)
(e) \( \alpha : \mathbb{R} \rightarrow \mathbb{R} \times \mathbb{R} \), where \( \alpha(x) = (x^2, 2x + 1) \).

10.68. Let \( S \) be a nonempty set. Show that there exists an injective function from \( \mathcal{P}(S) \) to \( \mathcal{P}(\mathcal{P}(S)) \).

10.69. Let \( A = \{a, b, c, d, e\} \). Then \( f = \{(a, c), (b, e), (c, d), (d, b), (e, a)\} \) is a bijective function from \( A \) to \( A \).

(a) Show that it is possible to list the five elements of \( A \) in such a way that the image of each of the first four elements on the list is to the immediate right of the element and that the image of the last element on the list is the first element on the list.

(b) Show that it is not possible to list elements of \( A \) as in (a) for every bijective function from \( A \) to \( A \).
Chapter 10 Functions

10.70. Let \( A = \mathbb{R} \setminus \{0\} \) and let \( f : A \to A \) be defined by \( f(x) = 1 - \frac{1}{x} \) for all \( x \in A \).
(a) Show that \( f \circ f = i_A \). (b) Determine \( f^{-1} \).

10.71. Give an example of a finite nonempty set \( A \) and a bijective function \( f : A \to A \) such that (1) \( f \neq i_A \), (2) \( f \circ f \neq i_A \) and (3) \( f \circ f \circ f = i_A \).

10.72. For nonempty sets \( A \) and \( B \) and functions \( f : A \to B \) and \( g : B \to A \), suppose that \( g \circ f = i_A \), the identity function on \( A \).
(a) Prove that \( f \) is one-to-one and \( g \) is onto.
(b) Show that \( f \) need not be onto.
(c) Show that \( g \) need not be one-to-one.
(d) Prove that if \( f \) is onto, then \( g \) is one-to-one.
(e) Prove that if \( g \) is one-to-one, then \( f \) is onto.
(f) Combine the results in (d) and (e) into a single statement.

10.73. Let \( A = \{1, 2\} \), \( B = \{1, -1, 2, -2\} \) and \( C = \{1, 2, 3, 4\} \). Then \( f = \{(1, 1), (1, -1), (2, 2), (2, -2)\} \) is a relation from \( A \) to \( B \) while \( g = \{(1, 1), (-1, 1), (2, 4), (-2, 4)\} \) is a relation from \( B \) to \( C \). Furthermore,
\[
gf = \{(x, z) : (x, y) \in f \text{ and } (y, z) \in g \text{ for some } y \in B\}
\]
is a relation from \( A \) to \( C \). Observe that even though the relation \( f \) is not a function from \( A \) to \( B \), the relation \( gf \) is a function from \( A \) to \( C \). Explain why.

10.74. A relation \( f \) on \( R \) is defined by \( f = \{(x, y) : x \in \mathbb{R} \text{ and } y = x \text{ or } y = -x\} \) and a function \( g : \mathbb{R} \to \mathbb{R} \) is defined by \( g(x) = x^2 \). Then
\[
gf = \{(x, z) : (x, y) \in f \text{ and } (y, z) \in g \text{ for some } y \in \mathbb{R}\}.
\]
(a) Explain why \( f \) is not a function from \( \mathbb{R} \) to \( \mathbb{R} \).
(b) Show that \( gf \) is a function from \( \mathbb{R} \) to \( \mathbb{R} \) and explicitly determine it.
(c) Even though the relation \( f \) is not a function from \( \mathbb{R} \) to \( \mathbb{R} \), the relation \( gf \) is a function from \( \mathbb{R} \) to \( \mathbb{R} \). Explain why.

10.75. Let \( A = \{1, 2\} \), \( B = \{1, 2, 3, 4\} \) and \( C = \{1, 2, 3, 4, 5, 6\} \). Give an example of a function \( f \) from \( A \) to \( B \) and a relation \( g \) from \( B \) to \( C \) that is not a function from \( B \) to \( C \) such that
\[
gf = \{(x, z) : (x, y) \in f \text{ and } (y, z) \in g \text{ for some } y \in B\}
\]
is a function from \( A \) to \( C \).

10.76. Let \( \mathcal{F} \) be the set of all functions with domain and codomain \( \mathbb{R} \). Define a relation \( R \) on \( \mathcal{F} \) by \( f R g \) if there exists a constant \( C \) such that \( f(x) = g(x) + C \) for all \( x \in \mathbb{R} \).
(a) Show that \( R \) is an equivalence relation.
(b) Let \( f \in \mathcal{F} \). If the derivative of \( f \) is defined for all \( x \in \mathbb{R} \), then use this information to describe the elements in the equivalence class \( [f] \).

10.77. Let \( \mathcal{S} \) be the set of odd positive integers. A function \( F : \mathbb{N} \to \mathcal{S} \) is defined by \( F(n) = k \) for each \( n \in \mathbb{N} \), where \( k \) is that odd positive integer for which \( 3n + 1 = 2^mk \) for some nonnegative integer \( m \). Prove or disprove the following:
(a) \( F \) is one-to-one. (b) \( F \) is onto.

10.78. A function \( F : \mathbb{N} \to \mathbb{N} \cup \{0\} \) is defined by \( F(n) = m \) for each \( n \in \mathbb{N} \), where \( m \) is that nonnegative integer for which \( 3n + 1 = 2^mk \) and \( k \) is an odd integer. Prove or disprove the following:
(a) \( F \) is one-to-one. (b) \( F \) is onto.
10.79. Recall that the derivative of \( \ln x \) is \( 1/x \) and that the derivative of \( x^n \) is \( nx^{n-1} \) for every integer \( n \). In symbols, \( \frac{d}{dx}(\ln x) = \frac{1}{x} \) and \( \frac{d}{dx}(x^n) = nx^{n-1} \). Let \( f : \mathbb{R}^+ \to \mathbb{R} \) be defined by \( f(x) = \ln x \) for every \( x \in \mathbb{R}^+ \). Prove that the \( nth \) derivative of \( f(x) \) is given by \( f^{(n)}(x) = \frac{(-1)^n e^{-x}(x-n)}{x^n} \) for every positive integer \( n \).

10.80. Let \( f : \mathbb{R} \to \mathbb{R} \) be defined by \( f(x) = xe^{-x} \) for every \( x \in \mathbb{R} \). Prove that the \( nth \) derivative of \( f(x) \) is given by \( f^{(n)}(x) = (-1)^n e^{-x}(x-n) \) for every positive integer \( n \).

10.81. The function \( h : \mathbb{Z}_{16} \to \mathbb{Z}_{24} \) is defined by \( h([a]) = [3a] \) for \( a \in \mathbb{Z} \).

(a) Prove that the function \( h \) is well-defined, that is, prove that if \( [a] = [b] \) in \( \mathbb{Z}_{16} \), then \( h([a]) = h([b]) \) in \( \mathbb{Z}_{24} \).

(b) For the subsets \( A = \{0, 3, 6, 9, 12, 15\} \) and \( B = \{0, 8\} \) of \( \mathbb{Z}_{16} \), determine the subsets \( h(A) \) and \( h(B) \) of \( \mathbb{Z}_{24} \).

(c) For the subsets \( C = \{0, 6, 16, 18\} \) and \( D = \{4, 8, 16\} \) of \( \mathbb{Z}_{24} \), determine \( h^{-1}(C) \) and \( h^{-1}(D) \).

10.82. Let \( f : \mathbb{R} - \{t\} \to \mathbb{R} - \{s\} \) be defined by \( f(x) = \frac{x}{x-t} \), where \( s, t \neq 0 \).

(a) Prove that \( f \) is bijective.

(b) Determine \( f^{-1}(x) \).

10.83. Let \( f : \mathbb{R} \to \mathbb{R} \) be defined by \( f(x) = \sqrt{1 - x^2} \).

(a) Prove that \( f \) is bijective.

(b) Determine \( f^{-1}(x) \).

10.84. Let \( \mathcal{U} \) be some universal set and \( A \) a subset of \( \mathcal{U} \). A function \( g_A : \mathcal{U} \to \{0, 1\} \) is defined by

\[
g_A(x) = \begin{cases} 1 & \text{if } x \in A \\ 0 & \text{if } x \notin A \end{cases}
\]

Verify each of the following.

(a) \( g_\mathcal{U}(x) = 1 \) for all \( x \in \mathcal{U} \).

(b) \( g_\emptyset(x) = 0 \) for all \( x \in \emptyset \).

(c) For \( \mathcal{U} = \mathbb{R} \) and \( A = [0, \infty) \), \( (g_A \circ g_A)(x) = 1 \) for \( x \in \mathbb{R} \).

(d) For subsets \( A \) and \( B \) of \( \mathcal{U} \) and \( C = A \cap B \), \( g_C = (g_A) \cdot (g_B) \), where \( ((g_A) \cdot (g_B))(x) = g_A(x) \cdot g_B(x) \).

(e) For \( A \subseteq \mathcal{U} \), \( g_A(x) = 1 - g_A(x) \) for each \( x \in \mathcal{U} \).

10.85. (a) Let \( S = \{a, b, c, d\} \) and let \( T \) be the set of all six 2-element subsets of \( S \). Show that there exists an injective function \( f : S \to \{0, 1, 2, \ldots, |T|\} \) such that the function \( g : T \to \{1, 2, \ldots, |T|\} \) defined by \( g(i, j) = |f(i) - f(j)| \) is bijective.

(b) Let \( S = \{a, b, c, d, e\} \) and let \( T \) be the set of all ten 2-element subsets of \( S \). Show that there exists no injective function \( f : S \to \{0, 1, 2, \ldots, |T|\} \) such that the function \( g : T \to \{1, 2, \ldots, |T|\} \) defined by \( g(i, j) = |f(i) - f(j)| \) is bijective.

(c) For the sets \( S \) and \( T \) in (b), show that there exists an injective function \( f : S \to \{0, 1, 2, \ldots, |T| + 2\} \) such that the function \( g : T \to \{1, 2, \ldots, |T| + 2\} \) defined by \( g(i, j) = |f(i) - f(j)| \) is injective.

(d) The results in (b) and (c) should suggest a question to you. Ask and answer such a question.
Many consider the Italian mathematician and scientist Galileo Galilei to be the founder of modern physics. Among his major contributions was his mathematical view of the laws of motion. Early in the 17th century, Galileo applied mathematics to study the motion of the earth. He was convinced that the earth revolved about the sun, an opinion not shared by the Catholic Church at that time. This led him to be imprisoned for the last nine years of his life.

Galileo’s two main scientific writings were *Dialogue Concerning the Two Chief World Systems* and *Discourses and Mathematical Demonstrations Concerning Two New Sciences*, the first published before he went to prison and the second published (in the Netherlands) while he was in prison. In these two works, he would often discuss scientific theories by means of a dialogue among fictional characters. It is in this manner that he could state his positions on various theories.

One topic that intrigued Galileo was infinite sets. Galileo observed that there is a one-to-one correspondence (that is, a bijective function) between the set $\mathbb{N}$ of positive integers and the subset $S$ of $\mathbb{N}$ consisting of the squares of positive integers. This led Galileo to observe that even though there are many positive integers that are not squares, there are as many squares as there are positive integers. This led Galileo to be faced with a property of an infinite set that he found bothersome: There can be a one-to-one correspondence between a set and a proper subset of the set. While Galileo concluded correctly that the number of squares of positive integers is not less than the number of positive integers, he could not bring himself to say that these sets have the same number of elements.

Bernhard Bolzano was a Bohemian priest, philosopher and mathematician. Although best known for his work in calculus during the first half of the 19th century, he too was interested in infinite sets. His *Paradoxes of the Infinite*, published two years after his death and unnoticed for twenty years, contained many ideas of the modern theory of sets. He noted that one-to-one correspondences between an infinite set and a proper subset of itself were common. Furthermore, Bolzano was comfortable with this fact, contrary to Galileo’s feelings. The German mathematician Richard Dedekind studied under the brilliant Carl Friedrich Gauss. Dedekind had a long and productive career in mathematics and made many contributions to the study of irrational numbers. What had confused Galileo and interested Bolzano gave rise to a definition of an infinite set by Dedekind during the last part of the 19th century: A set $S$ is infinite if it contains a proper subset that...
can be put in one-to-one correspondence with $S$. Certainly, then, understanding infinite sets was not an easy task, even among well-known mathematicians of the past.

We mentioned in Chapter 1 that the cardinality $|S|$ of a set $S$ is the number of elements in $S$ and, for the present, we would use the notation $|S|$ only when $S$ is a finite set. A set $S$ is **finite** if either $S = \emptyset$ or $|S| = n$ for some $n \in \mathbb{N}$; while a set is **infinite** if it is not finite. It may seem that we should write $|S| = \infty$ if $S$ is infinite but we will soon see that this is not particularly informative. Indeed, it is considerably more difficult to give a meaning to $|S|$ if $S$ is an infinite set; however, it is precisely this topic that we are about to explore.

### 11.1 Numerically Equivalent Sets

It is rather obvious that the sets $A = \{a, b, c\}$ and $B = \{x, y, z\}$ have the same cardinality since each has exactly three elements. That is, if we count the number of elements in two sets and arrive at the same value, then these two sets have the same cardinality. There is, however, another way to see that the sets $A$ and $B$ described above have the same cardinality without counting the elements in each set. Observe that we can pair off the elements of $A$ and $B$, say as $(a, x)$, $(b, y)$ and $(c, z)$. This implies that $A$ and $B$ have the same number of elements, that is, $|A| = |B|$. What we have actually done is describe a bijective function $f: A \to B$, namely $f = \{(a, x), (b, y), (c, z)\}$. Although it is much easier to see that $|A| = |B|$ by observing that each set has three elements than by constructing a bijective function from $A$ to $B$, it is this latter method of showing that $|A| = |B|$ that can be generalized to the situation where $A$ and $B$ are infinite sets.

Two sets $A$ and $B$ (finite or infinite) are said to have the same cardinality, written $|A| = |B|$, if either $A$ and $B$ are both empty or there is a bijective function from $A$ to $B$. Two sets having the same cardinality are also referred to as **numerically equivalent sets**. Two finite sets are therefore numerically equivalent if they are both empty or if both have $n$ elements for some positive integer $n$. Consequently, two nonempty sets $A$ and $B$ are not numerically equivalent, written $|A| \neq |B|$, if there is no bijective function from one set to the other. The study of numerically equivalent infinite sets is more challenging but considerably more interesting than the study of numerically equivalent finite sets.

The justification for the term “numerically equivalent sets” lies in the following theorem, which combines the major concepts of Chapters 9 and 10.

**Theorem 11.1** Let $S$ be a nonempty collection of nonempty sets. A relation $R$ is defined on $S$ by $A \ R \ B$ if there exists a bijective function from $A$ to $B$. Then $R$ is an equivalence relation.

**Proof** Let $A \in S$. Since the identity function $i_A: A \to A$ is bijective, it follows that $A \ R \ A$. Thus, $R$ is reflexive. Next, assume that $A \ R \ B$, where $A, B \in S$. Then there is a bijective function $f: A \to B$. By Theorem 10.15, $f$ has an inverse function $f^{-1}: B \to A$ and, furthermore, $f^{-1}$ is bijective. Therefore, $B \ R \ A$ and $R$ is symmetric.

Finally, assume that $A \ R \ B$ and $B \ R \ C$, where $A, B, C \in S$. Then there are bijective functions $f: A \to B$ and $g: B \to C$. It follows by Corollary 10.12 that the composition $g \circ f: A \to C$ is bijective as well and so $A \ R \ C$. Therefore, $R$ is transitive. Consequently, $R$ is an equivalence relation.
Chapter 11  Cardinalities of Sets

According to the equivalence relation defined in Theorem 11.1, if \( A \) is a nonempty set, then the equivalence class \([A]\) consists of all those elements of \( S\) having the same cardinality as \( A \); hence, the term “numerically equivalent sets” is natural for two sets having the same cardinality.

**Example 11.2** Let \( S = \{A_1, A_2, A_3, A_4, A_5, A_6\} \) where
\[
A_1 = \{1, 2, 3\}, \quad A_2 = \{a, b, c, d\}, \quad A_3 = \{x, y, z\}, \\
A_4 = \{r, s, t\}, \quad A_5 = \{m, n\}, \quad A_6 = \{7, 8, 9, 10\}.
\]
Then every two of the sets \( A_1, A_3 \) and \( A_4 \) are numerically equivalent, while \( A_2 \) and \( A_6 \) are numerically equivalent. This says that \( |A_1| = |A_3| = |A_4| \) and \( |A_2| = |A_6| \). The only set in \( S \) that is numerically equivalent to \( A_5 \) is \( A_5 \) itself. Thus,
\[
[A_1] = \{A_1, A_3, A_4\}, \quad [A_2] = \{A_2, A_6\} \quad \text{and} \quad [A_5] = \{A_5\}
\]
are the distinct equivalence classes of \( S \).

While Example 11.2 deals only with finite sets, it is infinite sets in which we will be primarily interested in this chapter. In particular, we will have a special interest in sets that are numerically equivalent to \( \mathbb{N} \) or to \( \mathbb{R} \).

**SECTION 11.1 EXERCISES**

11.1. Let \( S = \{A_1, A_2, A_3, A_4, A_5\} \) be a collection of five subsets of the set \( A = \{-5, -4, \ldots, 5\} \), where
\[
A_1 = \{x \in A : 1 < x^2 < 10\} \\
A_2 = \{x \in A : (x + 2)(x - 4) > 0\} \\
A_3 = \{x \in A : |x + 2| + |x - 3| \leq 5\} \\
A_4 = \{x \in A : \frac{1}{x+1} > \frac{2}{3}\} \\
A_5 = \{x \in A : \sin \frac{x}{4} = 0\}.
\]
A relation \( R \) is defined on \( S \) by \( A_i R A_j \) \((1 \leq i, j \leq 5)\) if \( A_i \) and \( A_j \) are numerically equivalent. According to Theorem 11.1, \( R \) is an equivalence relation. Determine the distinct equivalence classes for this equivalence relation.

11.2. (a) Let \( S \) be a collection of \( n \geq 2 \) numerically equivalent sets. Prove that these sets can be shown to be numerically equivalent by means of \( n - 1 \) bijective functions between pairs of sets in \( S \).

(b) What other question is suggested by the problem in (a)?

**11.2 DENUMERABLE SETS**

In order to start gaining an understanding of the cardinality of an infinite set, we begin with a particular class of infinite sets. A set \( A \) is called **denumerable** if \( |A| = |\mathbb{N}| \), that is, if \( A \) has the same cardinality as the set of natural numbers. Certainly, if \( A \) is denumerable, then \( A \) is infinite. By definition, if \( A \) is a denumerable set, then there is a bijective function \( f : \mathbb{N} \to A \) and so \( f = \{(1, f(1)), (2, f(2)), (3, f(3)), \ldots\} \). Consequently, \( A = \{f(1), f(2), f(3), \ldots\} \), that is, we can list the elements of \( A \) as \( f(1), f(2), f(3), \ldots \).
11.2 Denumerable Sets

Equivalently, we can list the elements of \( A \) as \( a_1, a_2, a_3, \ldots \), where then \( a_i = f(i) \) for \( i \in \mathbb{N} \). Conversely, if the elements of \( A \) can be listed as \( a_1, a_2, a_3, \ldots \), where \( a_i \neq a_j \) for \( i \neq j \), then \( A \) is denumerable since the function \( g : \mathbb{N} \to A \) defined by \( g(n) = a_n \) for each \( n \in \mathbb{N} \) is certainly bijective. Therefore, \( A \) is a denumerable set if and only if it is possible to list the elements of \( A \) as \( a_1, a_2, a_3, \ldots \) and so \( A = \{a_1, a_2, a_3, \ldots \} \).

A set is countable if it is either finite or denumerable. Countably infinite sets are then precisely the denumerable sets. Hence, if \( A \) is a nonempty countable set, then we can either write \( A = \{a_1, a_2, a_3, \ldots, a_n\} \) for some \( n \in \mathbb{N} \) or \( A = \{a_1, a_2, a_3, \ldots \} \). A set that is not countable is called uncountable. An uncountable set is necessarily infinite. It may not be clear whether any set is uncountable but we will soon see that such sets do exist.

Let’s look at a few examples of denumerable sets. Certainly, \( \mathbb{N} \) itself is denumerable since the identity function \( i_{\mathbb{N}} : \mathbb{N} \to \mathbb{N} \) is bijective. However, not only is the set of positive integers denumerable, the set of all integers is denumerable. The proof of this fact that we give illustrates a common technique for showing that a set is denumerable, namely, if we can list the elements of a set \( A \) as \( a_1, a_2, a_3, \ldots \) such that every element of \( A \) appears exactly once in the list, then \( A \) is denumerable.

Result 11.3 The set \( \mathbb{Z} \) of integers is denumerable.

Proof Observe that the elements of \( \mathbb{Z} \) can be listed as \( 0, 1, -1, 2, -2, \ldots \). Thus, the function \( f : \mathbb{N} \to \mathbb{Z} \) described in Figure 11.1 is bijective and so \( \mathbb{Z} \) is denumerable.

\[
\begin{array}{cccccc}
1 & 2 & 3 & 4 & 5 & \ldots \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow \\
0 & 1 & -1 & 2 & -2 & \ldots \\
\end{array}
\]

Figure 11.1 A bijective function \( f : \mathbb{N} \to \mathbb{Z} \)

The function \( f : \mathbb{N} \to \mathbb{Z} \) given in Figure 11.1 can also be defined by

\[
f(n) = \frac{1 + (-1)^n(2n-1)}{4}.
\]

Although we have already observed that this function \( f \) is bijective, Exercise 11.8 asks for a formal proof of this fact.

The fact that \( \mathbb{Z} \) is denumerable illustrates what Galileo had observed centuries ago: It is possible for two sets to have the same cardinality where one is a proper subset of the other. (Such a situation could never occur with finite sets, however.) For example, \( \mathbb{N} \subset \mathbb{Z} \) and \(|\mathbb{N}| = |\mathbb{Z}| \). This fact serves as an illustration of a result, the proof of which is a bit intricate.

Theorem to Prove Every infinite subset of a denumerable set is denumerable.

Proof Strategy In the proof, we begin with two sets, which we’ll call \( A \) and \( B \), where \( A \) is denumerable, \( B \subseteq A \) and \( B \) is infinite. Because \( A \) is denumerable, we can write \( A = \{a_1, a_2, a_3, \ldots \} \). Since our goal is to show that \( B \) is denumerable, we need to show that we can write \( B = \{b_1, b_2, b_3, \ldots \} \). The question, of course, is how to do it.
Chapter 11  Cardinals of Sets

Because $B$ is an infinite subset of $A$, some of the elements of $A$ belong to $B$ (in fact, infinitely many elements of $A$ belong to $B$); while, most likely, some elements of $A$ do not belong to $B$. We can keep track of the elements of $A$ that belong to $B$ by means of a set of positive integers, which we'll denote by $S$. If $a_1 \in B$, then $1 \in S$; if $a_1 \notin B$, then $1 \notin S$. In general, $n \in S$ if and only if $a_n \in B$. Certainly, $S \subseteq \mathbb{N}$. Since $\mathbb{N}$ is a well-ordered set (by the Well-Ordering Principle), $S$ contains a smallest element, say $s$. That is, $a_s \in B$. Furthermore, if $r$ is an integer such that $1 \leq r < s$, then $a_r \notin B$. It is the element $a_r$ that we will call $b_1$. It is now logical to look at the (infinite) set $S - \{s\}$ and consider its smallest element, say $t$. Thus, $t > s$. The element $a_t$ will become $b_2$. And so on.

Since we want to give a precise and careful proof, we are already faced with two problems. First, denoting the smallest element of $S$ by $s$ and denoting the smallest element of $S - \{s\}$ by $r$ will present difficulties to us. We need to use better notation. So, let us denote the smallest element of $S$ by $i_1$ (so $i_1 = a_s$) and the smallest element of $S - \{i_1\}$ by $i_2$ (so $i_2 = a_r$). This is much better notation. The other problem we have is when we wrote “And so on.” Once we have the positive integers $i_1$ and $i_2$, it will follow that the positive integer $i_3$ is the least element of $S - \{i_1, i_2\}$ in general, once we have determined the positive integers $i_1, i_2, \ldots, i_k$, where $k \in \mathbb{N}$, the positive integer $i_{k+1}$ is the smallest element of $S - \{i_1, i_2, \ldots, i_k\}$. In fact, this suggests that the elements $b_1, b_2, b_3, \ldots$ can be located in $A$ using induction.

After using induction to construct the set $\{b_1, b_2, b_3, \ldots\}$, which we will denote by $B'$, say, then we still have one more concern. Are we certain that $B' = B$? Because each element of $B'$ belongs to $B$, we know that $B' \subseteq B$. To show that $B' = B$, we must also be sure that $B \subseteq B'$. As we know, the standard way to show that $B \subseteq B'$ is to take an arbitrary element $b \in B$ and show that $b \in B'$.

Let's now write a complete proof.

\textbf{Theorem 11.4} Every infinite subset of a denumerable set is denumerable.

\textbf{Proof} Let $A$ be a denumerable set and let $B$ be an infinite subset of $A$. Since $A$ is denumerable, we can write $A = \{a_1, a_2, a_3, \ldots\}$. Let $S = \{i \in \mathbb{N} : a_i \in B\}$; that is, $S$ consists of all those positive integers that are subscripts of the elements in $A$ that also belong to $B$. Since $B$ is infinite, $S$ is infinite. First, we use induction to show that $B$ contains a denumerable subset. Since $S$ is a nonempty subset of $\mathbb{N}$, it follows from the Well-Ordering Principle that $S$ has a least element, say $i_1$. Let $b_1 = a_{i_1}$. Let $S_1 = S - \{i_1\}$. Since $S_1 \neq \emptyset$ (indeed, $S_1$ is infinite), $S_1$ has a least element, say $i_2$. Let $b_2 = a_{i_2}$, which, of course, is distinct from $b_1$. Assume that for an arbitrary integer $k \geq 2$, the (distinct) elements $b_1, b_2, \ldots, b_k$ have been defined by $b_j = a_{i_j}$ for each integer $j$ with $1 \leq j \leq k$, where $i_1$ is the smallest element in $S$ and $i_j$ is the minimum element in $S_{j-1} = S - \{i_1, i_2, \ldots, i_{j-1}\}$ for $2 \leq j \leq k$. Now let $i_{k+1}$ be the minimum element of $S_k = S - \{i_1, i_2, \ldots, i_k\}$ and let $b_{k+1} = a_{i_{k+1}}$. Hence, it follows that for each integer $n \geq 2$, an element $b_n$ belongs to $B$ that is distinct from $b_1, b_2, \ldots, b_{n-1}$. Thus, we have exhibited the elements $b_1, b_2, b_3, \ldots$ in $B$. Let $B' = \{b_1, b_2, b_3, \ldots\}$. Certainly $B' \subseteq B$. We claim, in fact, that $B = B'$. It remains only to show that $B \subseteq B'$. Let $b \in B$. Since $B \subseteq A$, it follows that $b = a_n$ for some $n \in \mathbb{N}$ and so $n \in S$. If $n = i_1$, then $b = b_1 = a_n$ and so $b \in B'$. Thus, we may assume that $n > i_1$. Let $S'$ consist of those positive integers less than $n$ that belong to $S$. Since $n > i_1$ and $i_1 \in S$, it follows that $S' \neq \emptyset$. Certainly, $1 \leq |S'| \leq n - 1$; so $S'$ is finite. Thus,
|S'| = m for some m ∈ N. The set S' therefore consists of the m smallest integers of S, that is, S' = {i₁, i₂, ..., iₘ}. The smallest integer that belongs to S and is greater than iₘ is iₘ₊₁, of course, and iₘ₊₁ ≥ n. But n ∈ S, so n = iₘ₊₁ and b = aₙ = aₘ₊₁ ∈ B'. Hence, B = B' = {b₁, b₂, b₃, ...}, which is denumerable.

In order to use Theorem 11.4 to describe other denumerable sets, it is convenient to introduce some additional notation. Let k ∈ N. Then the set kZ is defined by

$$kZ = \{kn : n ∈ Z\}.$$  

Similarly,

$$kN = \{kn : n ∈ N\}.$$  

Thus, 1Z = Z and 1N = N, while 2Z is the set of even integers. An immediate consequence of Theorem 11.4 is stated next.

**Result 11.5** The set 2Z of even integers is denumerable.

**Proof** Since 2Z is infinite and 2Z ⊆ Z, it follows by Theorem 11.4 that 2Z is denumerable. □

Of course, kZ is denumerable for every nonzero integer k. We now describe a denumerable set that can be obtained from two given denumerable sets. Recall, for sets A and B, that the Cartesian product A × B = {(a, b) : a ∈ A, b ∈ B}.

**Result 11.6** If A and B are denumerable sets, then A × B is denumerable.

**Proof** Since A and B are denumerable sets, we can write A = {a₁, a₂, a₃, ...} and B = {b₁, b₂, b₃, ...}. Consider the table shown in Figure 11.2(a), which has an infinite (denumerable) number of rows and columns, where the elements a₁, a₂, a₃, ... are written along the side and b₁, b₂, b₃, ... are written across the top. In row i, column j of the table, we place the ordered pair (aᵢ, bⱼ). Certainly, every element of A × B appears exactly once in this table. This table is reproduced in Figure 11.2(b), where the directed

![Figure 11.2](image-url)

**Figure 11.2** Constructing a bijective function f : N → A × B
lines indicate the order in which we will encounter the entries in the table. That is, we encounter the elements of \( A \times B \) in the order 

\[(a_1, b_1), (a_1, b_2), (a_2, b_1), (a_1, b_3), (a_2, b_2), \ldots. \]

Since every element of \( A \times B \) occurs in this list exactly once, this describes a bijective function \( f : \mathbb{N} \rightarrow A \times B \), where

\[f(1) = (a_1, b_1), f(2) = (a_1, b_2), f(3) = (a_2, b_1), f(4) = (a_1, b_3), f(5) = (a_2, b_2), \ldots.\]

Therefore, \( A \times B \) is denumerable.

We can use a technique similar to that used in proving Result 11.6 to show that another familiar set is denumerable.

**Result 11.7** The set \( \mathbb{Q}^+ \) of positive rational numbers is denumerable.

**Proof** Consider the table shown in Figure 11.3(a). In row \( i \), column \( j \), we place the rational number \( j/i \). Certainly, then, every positive rational number appears in the table of Figure 11.2(a); indeed, it appears infinitely often. For example, the number \( 1/2 \) appears in row 2, column 1, as well as in row 4, column 2.

![Figure 11.3](image-url)

A table used to show that \( \mathbb{Q}^+ \) is denumerable

The table of Figure 11.3(a) is reproduced in Figure 11.3(b), where the arrows indicate the order in which we will consider the entries in the table. That is, we now consider the positive rational numbers in the order

\[
\frac{1}{1}, \frac{2}{1}, \frac{1}{2}, \frac{3}{1}, \frac{2}{2}, \frac{1}{3}, \frac{4}{1}, \ldots.
\]

With the aid of this list, we can describe a bijective function \( f : \mathbb{N} \rightarrow \mathbb{Q}^+ \). In particular, we define \( f(1) = 1/1 = 1, f(2) = 2/1 = 2, f(3) = 1/2 \) and \( f(4) = 3/1 = 3 \) as expected. However, since \( 2/2 = 1 \) and we have already defined \( f(1) = 1 \), we do not define \( f(5) = 1 \) (since \( f \) must be one-to-one). We bypass \( 2/2 = 1 \) and, following the arrows, go directly to the next number on the list, namely \( 1/3 \). In fact, whenever we
encounter a number on the list that we have previously seen, we move to the next number on the list. In this manner, the function \( f \) being described will be one-to-one. The function \( f \) is shown in Figure 11.4.

\[
\begin{array}{cccccc}
1 & 2 & 3 & 4 & 5 & \cdots \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \\
1 & 2 & \frac{1}{2} & 3 & \frac{1}{3} & \cdots \\
\end{array}
\]

**Figure 11.4** A bijective function \( f : \mathbb{N} \rightarrow \mathbb{Q}^+ \)

Because every element of \( \mathbb{Q}^+ \) is eventually encountered, \( f \) is onto as well and so \( f \) is bijective. Consequently, \( \mathbb{Q}^+ \) is denumerable.

The function \( f \) described in Figure 11.4 is by no means unique. There are many ways to traverse the positive rational numbers in the table described in Figure 11.3(a). The tables shown in Figure 11.5 indicate two additional methods.

Some care must be taken when proceeding about the entries in the table of Figure 11.3(a). For example, traversing the positive rational numbers by rows (see Figure 11.6) just won’t do. Since the first row never ends, we will only encounter the positive integers.

The set \( \mathbb{Q}^+ \) can also be shown to be denumerable with the aid of the table in Figure 11.7. In the first row, all positive rational numbers \( j/i \) with \( i = 1 \) are shown. In the second row, all positive rational numbers \( j/i \) with \( i = 2 \) and such that \( j/i \) has been reduced to lowest terms are shown. This results in the rational number \( (2j - 1)/2 \) in row 2, column \( j \). We continue in this manner with all other rows. In this way, every positive rational number appears *exactly once* in the table. Thus, when we proceed through the entries as the arrows indicate, we obtain the positive rational numbers in the order

\[
\frac{1}{1}, \frac{2}{1}, \frac{1}{2}, \frac{3}{1}, \frac{1}{3}, \frac{3}{2}, \frac{1}{4}, \frac{4}{1}, \cdots
\]

and the corresponding bijective function \( g : \mathbb{N} \rightarrow \mathbb{Q}^+ \). Therefore, \( g(1) = 1, g(2) = 2, g(3) = 1/2, g(4) = 3, g(5) = 3/2 \) and so on.

1 & 1 & 2 & 3 & 4 & \ldots \\
1 & 1 & 1 & 1 & 1 & \ldots \\
2 & 1 & 2 & 3 & 4 & \ldots \\
2 & 2 & 2 & 2 & 2 & \ldots \\
3 & 1 & 2 & 3 & 4 & \ldots \\
3 & 3 & 3 & 3 & 3 & \ldots \\
4 & 1 & 2 & 3 & 4 & \ldots \\
4 & 4 & 4 & 4 & 4 & \ldots \\
\end{tabular}
\end{center}

\textbf{Figure 11.6}  How not to traverse the positive rational numbers

\begin{center}
\begin{tabular}{cccccc}
1 & 2 & 3 & 4 & \ldots \\
1 & 1 & 2 & 3 & 4 & \ldots \\
1 & 1 & 1 & 1 & 1 & \ldots \\
2 & 1 & 2 & 3 & 4 & \ldots \\
2 & 2 & 2 & 2 & 2 & \ldots \\
3 & 1 & 2 & 3 & 4 & \ldots \\
3 & 3 & 3 & 3 & 3 & \ldots \\
4 & 1 & 2 & 3 & 4 & \ldots \\
4 & 4 & 4 & 4 & 4 & \ldots \\
\end{tabular}
\end{center}

\textbf{Figure 11.7}  Another bijective function \( g : \mathbb{N} \to \mathbb{Q}^+ \)

Now that we have shown that \( \mathbb{Q}^+ \) is denumerable, it is not difficult to show that the set \( \mathbb{Q} \) of all rational numbers is denumerable.

\textbf{Result 11.8}  The set \( \mathbb{Q} \) of all rational numbers is denumerable.

\textbf{Proof}  Since \( \mathbb{Q}^+ \) is denumerable, we can write \( \mathbb{Q}^+ = \{q_1, q_2, q_3, \ldots \} \). Thus, \( \mathbb{Q} = \{0\} \cup \{q_1, q_2, q_3, \ldots \} \cup \{-q_1, -q_2, -q_3, \ldots \} \). Therefore, \( \mathbb{Q} = \{0, q_1, -q_1, q_2, -q_2, \ldots \} \) and the function \( f : \mathbb{N} \to \mathbb{Q} \) shown in Figure 11.8 is bijective and so \( \mathbb{Q} \) is denumerable. \( \blacksquare \)
11.3. Prove that if $A$ and $B$ are disjoint denumerable sets, then $A \cup B$ is denumerable.

11.4. Let $\mathbb{R}^+$ denote the set of positive real numbers and let $A$ and $B$ be denumerable subsets of $\mathbb{R}^+$. Define $C = \{x \in \mathbb{R} : -x \in B\}$. Show that $A \cup C$ is denumerable.

11.5. Let $S = \{x \in \mathbb{R} : x = \frac{n^2 + \sqrt{2}}{n}, n \in \mathbb{N}\}$.

Define $f : \mathbb{N} \to S$ by $f(n) = \frac{n^2 + \sqrt{2}}{n}$.

(a) List three elements that belong to $S$.
(b) Show that $f$ is one-to-one.
(c) Show that $f$ is onto.
(d) Is $S$ denumerable? Explain.

11.6. (a) Prove that the function $f : \mathbb{R} \to \mathbb{R}$ defined by $f(x) = \frac{2x}{x-1}$ is bijective.
(b) Explain why $|\mathbb{R} - \{1\}| = |\mathbb{R} - \{2\}|$.

11.7. Let $S = \{x \in \mathbb{R} : x = \frac{n^2 + \sqrt{2}}{n}, n \in \mathbb{N}\}$.

(a) Prove that $S$ is denumerable.
(b) Show that $\mathbb{R} \times \mathbb{N}$ is denumerable.

11.8. Prove that the function $f : \mathbb{N} \to \mathbb{Z}$ defined in (11.1) by $f(n) = \frac{1 + (-1)^n(2n-1)}{4}$ is bijective.

11.9. Show that every denumerable set $A$ can be partitioned into two denumerable subsets of $A$.

11.10. Let $A$ be a denumerable set and let $B = \{x, y\}$. Prove that $A \times B$ is denumerable.

11.11. Let $B$ be a denumerable set and let $A$ be an unspecified cardinality function $f : A \to B$ is a one-to-one function, then what can be said about the cardinality of $A$? Explain.

11.12. Prove that the set of all 2-element subsets of $\mathbb{N}$ is denumerable.

11.13. A Gaussian integer is a complex number of the form $a + bi$, where $a, b \in \mathbb{Z}$ and $i = \sqrt{-1}$. Show that the set $\mathbb{G}$ of Gaussian integers is denumerable.

11.14. Prove that $S = \{(a, b) : a, b \in \mathbb{N} \text{ and } b \geq 2a\}$ is denumerable.

11.15. Let $S \subseteq \mathbb{N} \times \mathbb{N}$ be defined by $S = \{(i, j) : i \leq j\}$. Show that $S$ is denumerable.

11.16. Let $A_1, A_2, A_3, \ldots$ be pairwise disjoint denumerable sets. Prove that $\cup_{i=1}^\infty A_i$ is denumerable.

11.17. Let $A = \{a_1, a_2, a_3, \ldots\}$. Define $B = A - \{a_n : n \in \mathbb{N}\}$. Prove that $|A| = |B|$.

11.18. A function $f : \mathbb{N} \times \mathbb{N} \to \mathbb{N}$ is defined by $f(m, n) = 2^{m-1}(2n-1)$.

(a) Prove that $f$ is one-to-one and onto.
(b) Show that $\mathbb{N} \times \mathbb{N}$ is denumerable.

11.19. Prove that every denumerable set $A$ can be partitioned into a denumerable number of denumerable subsets of $A$. 
288 Chapter 11 Cardinalities of Sets

11.3 UNCOUNTABLE SETS

Although we have now given several examples of denumerable sets (and consequently countably infinite sets), we have yet to give an example of an uncountable set. We will do this next. First though, let’s review a few facts about decimal expansions of real numbers. Every irrational number has a unique decimal expansion and this expansion is non-repeating, while every rational number has a repeating decimal expansion. For example, \( \frac{3}{7} = 0.272727 \cdots \). Some rational numbers, however, have two (repeating) decimal expansions. For example, \( \frac{1}{3} = 0.5000 \cdots \) and \( \frac{1}{7} = 0.4999 \cdots \). (The number \( \frac{5}{7} \) has only one decimal expansion.) In particular, a rational number \( \frac{a}{b} \), where \( a, b \in \mathbb{N} \), that is reduced to lowest terms has two decimal expansions if and only if the only primes that divide \( b \) are 2 or 5. If a rational number has two decimal expansions, then one of the expansions repeats the digit 0 from some point on (that is, the decimal expansion terminates), while the alternate expansion repeats the digit 9 from some point on.

We are now prepared to give an example of an uncountable set. Recall that for real numbers \( a \) and \( b \) with \( a < b \), the open interval \((a, b)\) is defined by

\[
(a, b) = \{ x \in \mathbb{R} : a < x < b \}.
\]

Although, as it will turn out, all open intervals \((a, b)\) of real numbers are uncountable, we will prove now only that \((0, 1)\) is uncountable.

**Theorem to Prove**

The open interval \((0, 1)\) of real numbers is uncountable.

**Proof Strategy**

Since uncountable means not countable, it is not surprising that we should try a proof by contradiction here. So the proof would begin by assuming that \((0, 1)\) is countable. Since \((0, 1)\) is an infinite set, this means that we are assuming that \((0, 1)\) is denumerable, which implies that there must exist a bijective function \( f : \mathbb{N} \rightarrow (0, 1) \). Therefore, for each \( n \in \mathbb{N} \), \( f(n) \) is a number in the set \((0, 1)\). It might be convenient to introduce some notation for the number \( f(n) \), say \( f(n) = a_n \), where then \( 0 < a_n < 1 \). Since \( f \) is assumed to be one-to-one, it follows that \( a_i \neq a_j \) for distinct positive integers \( i \) and \( j \). Each number \( a_n \) has a decimal expansion, say \( a_n = 0.a_{n1}a_{n2}a_{n3} \cdots \), where \( a_{n1} \) is the first digit in the expansion, \( a_{n2} \) is the second digit in the expansion and so on. We have to be a bit careful here, however, for, as we have seen, some real numbers have two decimal expansions. To avoid possible confusion, we can choose the decimal expansion that repeats the digit 0 from some point on. That is, no real number \( a_n \) has a decimal expansion that repeats 9 from some point on.

But where does this lead to a contradiction? From what we have said, \((0, 1) = \{a_1, a_2, a_3, \ldots \}\). If we can think of some real number \( b \in (0, 1) \) such that \( b \notin \{a_1, a_2, a_3, \ldots \} \), then this would give us a contradiction because this would say that \( f \) is not onto.

So, we need to find a number \( b \in (0, 1) \) such that \( b \neq a_n \) for each \( n \in \mathbb{N} \). Since \( b \in (0, 1) \), the number \( b \) has a decimal expansion, say \( b = 0.b_1b_2b_3 \cdots \). How can we choose the digits \( b_1, b_2, b_3, \ldots \) so that \( b \neq a_n \) for every \( n \in \mathbb{N} \)? We could choose \( b_1 \neq a_{11}, b_2 \neq a_{22}, \) etc. But would this mean that \( b \neq a_1, b \neq a_2, \) etc? Care must be taken here as well. For example, 0.5000... and 0.4999... are two equal numbers whose first digits in their expansions are not equal. Of course, the reason for this is that one is the alternate decimal expansion.
11.3 Uncountable Sets

of the other. Thus, provided we can avoid selecting a decimal expansion for \( b \) that is the alternate decimal expansion for some number \( a_n \), where \( n \in \mathbb{N} \), we will have found a number \( b \in (1, 0) \) such that \( b \notin \{a_1, a_2, a_3, \ldots\} \). This will give us a contradiction. ♦

**Theorem 11.9** The open interval \((0, 1)\) of real numbers is uncountable.

**Proof** Assume, to the contrary, that \((0, 1)\) is countable. Since \((0, 1)\) is infinite, it is denumerable. Therefore, there exists a bijective function \( f : \mathbb{N} \rightarrow (0, 1) \). For \( n \in \mathbb{N} \), let \( f(n) = a_n \). Since \( a_n \in (0, 1) \), the number \( a_n \) has a decimal expansion, say \( 0.a_{n1}a_{n2}a_{n3} \cdots \), where \( a_{ni} \in \{0, 1, 2, \ldots, 9\} \) for all \( i \in \mathbb{N} \). If \( a_n \) is irrational, then its decimal expansion is unique. If \( a_n \in \mathbb{Q} \), then the expansion may be unique. If it is not unique, then, without loss of generality, we assume that the digits of the decimal expansion \( 0.a_{n1}a_{n2}a_{n3} \cdots \) are 0 from some position on. For example, since \( f \) is bijective, \( 2/5 \) is the image of exactly one positive integer and this image is written as \( 0.4000 \cdots \) (rather than as \( 0.3999 \cdots \)). To summarize, we have

\[
\begin{align*}
f(1) &= a_1 = 0.a_{11}a_{12}a_{13} \cdots \\
f(2) &= a_2 = 0.a_{21}a_{22}a_{23} \cdots \\
f(3) &= a_3 = 0.a_{31}a_{32}a_{33} \cdots \\
& \vdots & & \vdots & & \vdots
\end{align*}
\]

We show that the function \( f \) is not onto, however. Define the number \( b = 0.b_1b_2b_3 \cdots \), where \( b_i \in \{4, 5\} \) for all \( i \in \mathbb{N} \), by

\[
b_i = \begin{cases} 
4 & \text{if } a_{ii} = 5 \\
5 & \text{if } a_{ii} \neq 5.
\end{cases}
\]

(For example, let’s suppose that \( a_1 = 0.31717 \cdots, a_2 = 0.151515 \cdots \) and \( a_3 = 0.04000 \cdots \). Then the first three digits in the decimal expansion of \( b \) are 5, 4 and 5, that is, \( b = 0.545 \cdots \).)

For each \( i \in \mathbb{N} \), the digit \( b_i \neq a_{ii} \), implying that \( b \neq a_n \) for all \( n \in \mathbb{N} \) since \( b \) is not the alternate expansion of any rational number, as no digit in the expansion of \( b \) is 9. Thus, \( b \) is not an image of any element of \( \mathbb{N} \). Therefore, \( f \) is not onto and, consequently, not bijective, producing a contradiction. ■

In the proof of Theorem 11.9, each digit in the decimal expansion of the number \( b \) constructed is 4 or 5. We could have selected any two distinct digits that did not use 9. It is now easy to give examples of other uncountable sets with the aid of the following result.

**Theorem 11.10** Let \( A \) and \( B \) be sets such that \( A \subseteq B \). If \( A \) is uncountable, then \( B \) is uncountable.

**Proof** Let \( A \) and \( B \) be two sets such that \( A \subseteq B \) and \( A \) is uncountable. Necessarily then \( A \) and \( B \) are infinite. Assume, to the contrary, that \( B \) is denumerable. Since \( A \) is an infinite subset of a denumerable set, it follows by Theorem 11.4 that \( A \) is denumerable, producing a contradiction. ■

**Corollary 11.11** The set \( \mathbb{R} \) of real numbers is uncountable.
Chapter 11  Cardinalities of Sets

Proof Since $(0, 1)$ is uncountable by Theorem 11.9 and $(0, 1) \subseteq \mathbb{R}$, it follows by Theorem 11.10 that $\mathbb{R}$ is uncountable.

Let’s pause for a moment to review a few facts that we’ve discovered about infinite sets (at least about certain infinite sets). First, recall that two nonempty sets $A$ and $B$ are defined to have the same cardinality (same number of elements) if there exists a bijective function from $A$ to $B$. We’re especially interested in the situation when $A$ and $B$ are infinite. One family of infinite sets we’ve introduced is the class of denumerable sets. Recall too that a set $S$ is denumerable if there exists a bijective function from $\mathbb{N}$ to $S$.

Suppose that $A$ and $B$ are two denumerable sets. Then there exist bijective functions $f : \mathbb{N} \to A$ and $g : \mathbb{N} \to B$. Since $f$ is bijective, $f$ has an inverse function $f^{-1} : A \to \mathbb{N}$, where $f^{-1}$ is also bijective (Theorem 10.15). Since $f^{-1} : A \to \mathbb{N}$ and $g : \mathbb{N} \to B$ are bijective functions, it follows that the composition function $g \circ f^{-1} : A \to B$ is also bijective (Corollary 10.12). This tells us that $|A| = |B|$, that is, $A$ and $B$ have the same number of elements. We state this as a theorem for emphasis.

Theorem 11.12  Every two denumerable sets are numerically equivalent.

Next, suppose that $B$ is an uncountable set. So, $B$ is an infinite set that is not denumerable. In addition, suppose that $A$ is a denumerable set. Therefore, there exists a bijective function $f : \mathbb{N} \to A$. We claim that $|A| \neq |B|$, that is, $A$ and $B$ do not have the same number of elements. Let’s prove this. Assume, to the contrary, that $|A| = |B|$. Hence, there exists a bijective function $g : A \to B$. Since the functions $f : \mathbb{N} \to A$ and $g : A \to B$ are bijective, the composition function $g \circ f : \mathbb{N} \to B$ is bijective. But this means that $B$ is a denumerable set, which is a contradiction. We also state this fact as a theorem.

Theorem 11.13  If $A$ is a denumerable set and $B$ is an uncountable set, then $A$ and $B$ are not numerically equivalent.

Theorems 11.12 and 11.13 can also be considered as consequences of Theorem 11.1. In particular, Theorem 11.13 says that $\mathbb{Z}$ and $\mathbb{R}$ are not numerically equivalent and so $|\mathbb{Z}| \neq |\mathbb{R}|$. So, here are two infinite sets that do not have the same number of elements. In other words, there are different sizes of infinity. This now brings up a number of questions, one of which is: Do there exist three infinite sets so that no two of them have the same number of elements? Also, if $A$ is a denumerable set and $B$ is an uncountable set, is one of these sets “bigger” than the other in some sense? In other words, we would like to be able to compare $|A|$ and $|B|$ in some precise manner. Since $|\mathbb{Z}| \neq |\mathbb{R}|$ and $\mathbb{Z} \subset \mathbb{R}$, it is tempting to conclude that $|\mathbb{Z}| < |\mathbb{R}|$ but we have yet to give a meaning to $|A| < |B|$ for infinite sets $A$ and $B$. This idea will be addressed in Section 11.4. We should remind ourselves, however, that for infinite sets $C$ and $D$, it is possible that both $C \subset D$ and $|C| = |D|$. For example, $\mathbb{Z} \subset \mathbb{Q}$ and $|\mathbb{Z}| = |\mathbb{Q}|$ since $\mathbb{Z}$ and $\mathbb{Q}$ are both denumerable.

Before leaving our discussion of $\mathbb{Z}$ and $\mathbb{R}$, one other observation is useful. Recall that, according to Theorem 11.4, if $B$ is an infinite subset of a denumerable set $A$, then $B$ is also denumerable. But what if $A$ is uncountable? That is, if $B$ is an infinite subset of an uncountable set $A$, can we conclude that $B$ is uncountable? The sets $\mathbb{Z}$ and $\mathbb{R}$ answer this question since $\mathbb{Z}$ is infinite, $\mathbb{R}$ is uncountable and $\mathbb{Z} \subset \mathbb{R}$. However, $\mathbb{Z}$ is not uncountable.
11.3 Uncountable Sets

We have now seen two examples of uncountable sets, namely the open interval \((0, 1)\) of real numbers and the set \(\mathbb{R}\) of all real numbers. Neither of these sets have the same number of elements as any denumerable set. But how do they compare with each other? We will show, in fact, that these two sets have the same number of elements. Prior to verifying this, we show that the open interval \((-1, 1)\) and \(\mathbb{R}\) have the same number of elements.

**Theorem to Prove**

The sets \((-1, 1)\) and \(\mathbb{R}\) are numerically equivalent.

**Proof Strategy**

The obvious approach to proving this theorem is to locate a bijective function \(f : (-1, 1) \to \mathbb{R}\). Actually, there are several such functions with this property. With each such function, we are faced with the problem of determining how involved it is to show that the function is bijective. We describe one of these here. Another is given in Exercise 11.25. Consider the function \(f : (-1, 1) \to \mathbb{R}\) defined by

\[
f(x) = \frac{x}{1 - |x|}.
\]

(See Figure 11.9.) This function is defined for all \(x \in (-1, 1)\). Observe that \(f(0) = 0\), \(f(x) > 0\) when \(0 < x < 1\) and \(f(x) < 0\) when \(-1 < x < 0\). This function also has the property that

\[
\lim_{x \to 1^-} \frac{x}{1 - |x|} = +\infty \quad \text{and} \quad \lim_{x \to -1^+} \frac{x}{1 - |x|} = -\infty.
\]

If you recall enough information about continuous functions from calculus, you might see that this function is continuous on the interval \((-1, 1)\). From this information, it follows that \(f((-1, 1)) = \mathbb{R}\) and that \(f\) is onto. Also, the derivative of this function on the interval \((-1, 1)\) is

\[
f'(x) = \begin{cases} 
\frac{1}{(1-x)^2} & \text{if } x \in (0, 1) \\
1 & \text{if } x = 0 \\
\frac{1}{(1+x)^2} & \text{if } x \in (-1, 0).
\end{cases}
\]

This says that \(f'(x) > 0\) for all \(x \in (-1, 1)\) and so \(f\) is an increasing function on the interval \((-1, 1)\). This information tells us that \(f\) must be one-to-one and so \(f\) is bijective.

![Figure 11.9](image-url)
While the argument just given relies on calculus and you may not recall all of this, an argument can be given that is of the type we have been discussing.

Theorem 11.14  The sets \((-1, 1)\) and \(\mathbb{R}\) are numerically equivalent.

Proof  Consider the function \(f : (-1, 1) \to \mathbb{R}\) defined by

\[
f(x) = \frac{x}{1 - |x|}.
\] (11.2)

We show that \(f\) is bijective. First, we verify that \(f\) is one-to-one. Let \(f(a) = f(b)\), where \(a, b \in (-1, 1)\). Then

\[
\frac{a}{1-|a|} = \frac{b}{1-|b|}.
\]

If \(\frac{a}{1-|a|} = \frac{b}{1-|b|} = 0\), then \(a = b = 0\). If \(\frac{a}{1-|a|} = \frac{b}{1-|b|} > 0\), then \(a > 0\) and \(b > 0\). Thus, \(\frac{a}{1-|a|} = \frac{b}{1-|b|}\). Hence, \(a(1-b) = b(1-a)\) and so \(a = b\). If \(\frac{a}{1-|a|} = \frac{b}{1-|b|} < 0\), then \(a < 0\) and \(b < 0\). Thus, \(\frac{a}{1+a} = \frac{b}{1+b}\). Hence, \(a(1+b) = b(1+a)\) and so \(a = b\). Therefore, \(f\) is one-to-one.

Next, we show that \(f\) is onto. Let \(r \in \mathbb{R}\). Since \(f(0) = 0\), we may assume that \(r \neq 0\). If \(r > 0\), then \(\frac{r}{1+r} \in (0, 1)\) and \(f\left(\frac{r}{1+r}\right) = r\). If \(r < 0\), then \(\frac{r}{1+r} \in (-1, 0)\) and \(f\left(-\frac{r}{1+r}\right) = r\). Thus, \(f\) is onto.

Since \(f\) is a bijective function, the sets \((-1, 1)\) and \(\mathbb{R}\) are numerically equivalent.

It is straightforward to show that the function \(g : (0, 1) \to (-1, 1)\) defined by \(g(x) = 2x - 1\) is bijective. For this function \(g\) and the function \(f\) in (11.2) in the proof of Theorem 11.14, it therefore follows that \(f \circ g : (0, 1) \to \mathbb{R}\) is also bijective. This gives an immediate corollary.

Corollary 11.15  The sets \((0, 1)\) and \(\mathbb{R}\) are numerically equivalent.

Not only are \((0, 1)\) and \(\mathbb{R}\) numerically equivalent (as well as \((-1, 1)\) and \(\mathbb{R}\)), but every open interval \((a, b)\) of real numbers with \(a < b\) and \(\mathbb{R}\) are numerically equivalent. (See Exercise 11.23.)

SECTION 11.3 EXERCISES

11.20. Prove that the set of irrational numbers is uncountable.

11.21. Prove that the set of complex numbers is uncountable.

11.22. Prove that the open interval \((-2, 2)\) and \(\mathbb{R}\) are numerically equivalent by finding a bijective function \(h : (-2, 2) \to \mathbb{R}\). (Show that your function is, in fact, bijective.)

11.23. (a) Prove that the function \(f : (0, 1) \to (0, 2)\), mapping the open interval \((0, 1)\) into the open interval \((0, 2)\) and defined by \(f(x) = 2x\), is bijective.

(b) Explain why \((0, 1)\) and \((0, 2)\) have the same cardinality.

(c) Let \(a, b \in \mathbb{R}\), where \(a < b\). Prove that \((0, 1)\) and \((a, b)\) have the same cardinality.

11.24. Prove that \(\mathbb{R}\) and \(\mathbb{R}^+\) are numerically equivalent.

11.25. Consider the function \(g : (-1, 1) \to \mathbb{R}\) defined by \(g(x) = \frac{x}{1-x^2}\).

(a) Prove that \(g\) is onto.

(b) Prove that \(g\) is one-to-one.

(c) From the information obtained in (a) and (b), what conclusion can be made?
11.4 COMPARING CARDINALITIES OF SETS

As we know, two nonempty sets $A$ and $B$ have the same cardinality if there exists a bijective function $f : A \to B$. Let’s illustrate this concept one more time by showing that two familiar sets associated with a given set are numerically equivalent. Recall that the power set $\mathcal{P}(A)$ of a set $A$ is the set of all subsets of $A$ and that $2^A$ is the set of all functions from $A$ to $\{0, 1\}$. If $A = \{a, b, c\}$, then $|\mathcal{P}(A)| = 2^3 = 8$. Also, the set $2^A$ contains $2^{|A|} = 2^3 = 8$ functions. So in this case, $\mathcal{P}(A)$ and $2^A$ have the same number of elements. This is not a coincidence.

**Theorem to Prove**
For every nonempty set $A$, the sets $\mathcal{P}(A)$ and $2^A$ are numerically equivalent.

**Proof Strategy**
If we can construct a bijective function $\phi : \mathcal{P}(A) \to 2^A$, then this will prove that $\mathcal{P}(A)$ and $2^A$ are numerically equivalent. We use $\phi$ for this function since $2^A$ is a set of functions and it is probably better to use more standard notation, such as $f$, to denote the elements of $2^A$. But how can such a function $\phi$ be defined? Let’s take a look at $\mathcal{P}(A)$ and $2^A$ for $A = \{a, b\}$. In this case, $
\mathcal{P}(A) = \{\emptyset, \{a\}, \{b\}, \{a, b\}\};$
while $2^A = \{f_1, f_2, f_2, f_4\}$, where

$f_1 = \{(a, 0), (b, 0)\}, \quad f_2 = \{(a, 1), (b, 0)\},$

$f_3 = \{(a, 0), (b, 1)\}, \quad f_4 = \{(a, 1), (b, 1)\}.$

Since each of $\mathcal{P}(A)$ and $2^A$ has four elements, we can easily find a bijective function from $\mathcal{P}(A)$ to $2^A$. But this is not the question. What we are looking for is a bijective function $\phi : \mathcal{P}(A) \to 2^A$ for $A = \{a, b\}$ that suggests a way for us to define a bijective function from $\mathcal{P}(A)$ to $2^A$ for any set $A$ (finite or infinite). Notice, for $A = \{a, b\}$, the connection between the following pairs of elements, the first element belonging to $\mathcal{P}(A)$ and the second belonging to $2^A$:

$\emptyset, \quad f_1 = \{(a, 0), (b, 0)\}$

$\{a\}, \quad f_2 = \{(a, 1), (b, 0)\}$

$\{b\}, \quad f_3 = \{(a, 0), (b, 1)\}$

$\{a, b\}, \quad f_4 = \{(a, 1), (b, 1)\}.$

For example, the subset $\{a\}$ of $\{a, b\}$ contains $a$ but not $b$, while $f_2$ maps $a$ to 1 and $b$ to 0. For an arbitrary set $A$, this suggests defining $\phi$ so that a subset $S$ of $A$ is mapped into the function in which 1 is the image of elements of $A$ that belong to $S$ and 0 is the image of elements of $A$ that do not belong to $S$.

**Theorem 11.16**
For every nonempty set $A$, the sets $\mathcal{P}(A)$ and $2^A$ are numerically equivalent.

**Proof**
We show that there exists a bijective function $\phi$ from $\mathcal{P}(A)$ to $2^A$. Define $\phi : \mathcal{P}(A) \to 2^A$ such that for $S \in \mathcal{P}(A)$, we have $\phi(S) = f_S$, where, for $x \in A$,

$f_S(x) = \begin{cases} 1 & \text{if } x \in S \\ 0 & \text{if } x \notin S. \end{cases}$
Certainly, \( f_S \in 2^A \). First, we show that \( \phi \) is one-to-one. Let \( \phi(S) = \phi(T) \). Thus, \( f_S = f_T \), which implies that \( f_S(x) = f_T(x) \) for every \( x \in A \). Therefore, \( f_S(x) = 1 \) if and only if \( f_T(x) = 1 \) for every \( x \in A \); that is, \( x \in S \) if and only if \( x \in T \) and so \( S = T \).

It remains to show that \( \phi \) is onto. Let \( f \in 2^A \). Define

\[
S = \{ x \in A : f(x) = 1 \}.
\]

Hence, \( f_S = f \) and so \( \phi(S) = f \). Thus, \( \phi \) is onto and, consequently, \( \phi \) is bijective.

It is clear that \( A = \{ x, y, z \} \) has fewer elements than \( B = \{ a, b, c, d, e \} \), that is, \(|A| < |B|\). And it certainly seems that \(|B| < |\mathbb{N}|\) and that, in general, any finite set has fewer elements than any denumerable set (or than any infinite set). Also, our discussion about countable and uncountable sets appears to suggest that uncountable sets have more elements than countable sets. But these assertions are based on intuition. We now make this more precise.

A set \( A \) is said to have **smaller cardinality** than a set \( B \), written as \(|A| < |B|\), if there exists a one-to-one function from \( A \) to \( B \) but no bijective function from \( A \) to \( B \). That is, \(|A| < |B|\) if it is possible to pair off the elements of \( A \) with some of the elements of \( B \) but not with all of the elements of \( B \). If \(|A| < |B|\), then we also write \(|B| > |A|\). For example, since \( \mathbb{N} \) is denumerable and \( \mathbb{R} \) is uncountable, there is no bijective function from \( \mathbb{N} \) to \( \mathbb{R} \). Since the function \( f : \mathbb{N} \rightarrow \mathbb{R} \) defined by \( f(n) = n \) for all \( n \in \mathbb{N} \) is injective, it follows that \(|\mathbb{N}| < |\mathbb{R}|\). Moreover, \(|A| \leq |B|\) means that \(|A| = |B| \) or \(|A| < |B|\). Hence, to verify that \(|A| \leq |B|\), we need only show the existence of a one-to-one function from \( A \) to \( B \).

The cardinality of the set \( \mathbb{N} \) of natural numbers is often denoted by \( \aleph_0 \) (often read “aleph null”); so \(|\mathbb{N}| = \aleph_0 \). Actually, \( \aleph \) is the first letter of the Hebrew alphabet. Indeed, if \( A \) is any denumerable set, then \(|A| = \aleph_0 \). The set \( \mathbb{R} \) of real numbers is also referred to as the **continuum** and its cardinality is denoted by \( c \). Hence, \(|\mathbb{R}| = c \) and from what we have seen, \( \aleph_0 < c \). It was the German mathematician Georg Cantor who helped to put the theory of sets on a firm foundation. An interesting conjecture of his became known as:

**The Continuum Hypothesis**

There exists no set \( S \) such that

\[
\aleph_0 < |S| < c.
\]

Of course, if the Continuum Hypothesis were true, then this would imply that every subset of \( \mathbb{R} \) is either countable or is numerically equivalent to \( \mathbb{R} \). However, in 1931 the Austrian mathematician Kurt Gödel proved that it was impossible to disprove the Continuum Hypothesis from the axioms on which the theory of sets is based. In 1963 the American mathematician Paul Cohen took it one step further by showing that it was also impossible to **prove** the Continuum Hypothesis from these axioms. Thus, the Continuum Hypothesis is independent of the axioms of set theory.

Another question that might occur to you is the following: Is there a set \( S \) such that \(|S| > c|\)? This is a question we can answer, however, and the answer might be surprising.

**Theorem to Prove**

If \( A \) is a set, then \(|A| < |\mathcal{P}(A)|\).
PROOF STRATEGY

First, it is not surprising that \(|A| < |\mathcal{P}(A)|\) if \(A\) is finite, for if \(A\) has \(n\) elements, where \(n \in \mathbb{N}\), then \(\mathcal{P}(A)\) has \(2^n\) elements and \(2^n > n\) (which was proved by induction in Result 6.16). Of course, we must still show that \(|A| < |\mathcal{P}(A)|\) when \(A\) is infinite. First, we show that there exists a one-to-one function \(f : A \to \mathcal{P}(A)\) for every set \(A\). Let’s give ourselves an example, say \(A = \{a, b\}\). Then \(\mathcal{P}(A) = \{\emptyset, \{a\}, \{b\}, \{a, b\}\}\). Although there are many injective functions from \(A\) to \(\mathcal{P}(A)\), there is one natural injective function:

\[
f = \{(a, \{a\}), (b, \{b\})\};
\]

in other words, define \(f : A \to \mathcal{P}(A)\) by \(f(x) = \{x\}\).

Once we have verified that this function is one-to-one, then we know that \(|A| \leq |\mathcal{P}(A)|\). To show that the inequality is strict, however, we must prove that there is no bijective function from \(A\) to \(\mathcal{P}(A)\). The natural technique to verify this is proof by contradiction.

Theorem 11.17 If \(A\) is a set, then \(|A| < |\mathcal{P}(A)|\).

Proof If \(A = \emptyset\), then \(|A| = 0\) and \(|\mathcal{P}(A)| = 1\); so \(|A| < |\mathcal{P}(A)|\). Hence, we may assume that \(A \neq \emptyset\). First, we show that there is a one-to-one function from \(A\) to \(\mathcal{P}(A)\). Define the function \(f : A \to \mathcal{P}(A)\) by \(f(x) = \{x\}\) for each \(x \in A\). Let \(f(x_1) = f(x_2)\). Then \(\{x_1\} = \{x_2\}\). So, \(x_1 = x_2\) and \(f\) is one-to-one.

To prove that \(|A| < |\mathcal{P}(A)|\), it remains to show that there is no bijective function from \(A\) to \(\mathcal{P}(A)\). Assume, to the contrary, that there exists a bijective function \(g : A \to \mathcal{P}(A)\). For each \(x \in A\), let \(g(x) = A_x\), where \(A_x \subseteq A\). We show that there is a subset of \(A\) that is distinct from \(A_x\) for each \(x \in A\). Define the subset \(B\) of \(A\) by

\[
B = \{x \in A : x \notin A_x\}.
\]

By assumption, there exists an element \(y \in A\) such that \(B = A_y\). If \(y \in A_y\), then \(y \notin B\) by the definition of \(B\). On the other hand, if \(y \notin A_y\), then, according to the definition of the set \(B\), it follows that \(y \in B\). In either case, \(y\) belongs to exactly one of \(A_y\) and \(B\). Hence, \(B \neq A_y\), producing a contradiction.

According to Theorem 11.17, there is no largest set. In particular, there is a set \(S\) with \(|S| > c|\).

SECTION 11.4 EXERCISES

11.26. Prove or disprove the following:

(a) If \(A\) is an uncountable set, then \(|A| = |\mathbb{R}|\).
(b) There exists a bijective function \(f : \mathbb{Q} \to \mathbb{R}\).
(c) If \(A, B\) and \(C\) are sets such that \(A \subseteq B \subseteq C\) and \(A\) and \(C\) are denumerable, then \(B\) is denumerable.
(d) The set \(S = \left\{ \frac{\sqrt{2}}{n} : n \in \mathbb{N} \right\}\) is denumerable.
(e) There exists a denumerable subset of the set of irrational numbers.
(f) Every infinite set is a subset of some denumerable set.
(g) If \(A\) and \(B\) are sets with the property that there exists an injective function \(f : A \to B\), then \(|A| = |B|\).
296  Chapter 11  Cardinalities of Sets

11.27. Let \( A \) and \( B \) be nonempty sets. Prove that \( |A| \leq |A \times B| \).
11.28. Prove or disprove: If \( A \) and \( B \) are two sets such that \( A \) is countable and \( |A| < |B| \), then \( B \) is uncountable.
11.29. How do the cardinalities of the sets \([0, 1] \) and \([1, 3] \) compare? Justify your answer.
11.30. Let \( A = \{a, b, c\} \). Then \( \mathcal{P}(A) \) consists of the following subsets of \( A \):

\[
A_a = \emptyset, A_b = A, A_c = \{a, b\}, A_d = \{a, c\},
A_e = \{b, c\}, A_f = \{a\}, A_g = \{b\}, A_h = \{c\}.
\]

In one part of the proof of Theorem 11.17, it was established (using a contradiction argument) that \( |A| < |\mathcal{P}(A)| \) for every nonempty set \( A \). In this argument, the existence of a bijective function \( g : A \to \mathcal{P}(A) \) is assumed, where \( g(x) = A_x \) for each \( x \in A \). Then a subset \( B \) of \( A \) is defined by

\[
B = \{x \in A : x \notin A_x\}.
\]

(a) For the sets \( A \) and \( \mathcal{P}(A) \) described above, what is the set \( B \)?
(b) What does the set \( B \) in (a) illustrate?

11.31. Prove or disprove: There is no set \( A \) such that \( 2^A \) is denumerable.

11.5 THE SCHröDER-BERNSTEIN THEOREM

Let \( f \) be a function from a set \( A \) to a set \( B \) and let \( D \) be a nonempty subset of \( A \). By the restriction \( f_1 \) of \( f \) to \( D \), we mean the function

\[
f_1 = \{(x, y) \in f : x \in D\}.
\]

Hence, a restriction of \( f \) refers to restricting the domain of \( f \). For example, for the sets \( A = \{a, b, c, d\} \) and \( B = \{1, 2, 3\} \), let \( f = \{(a, 2), (b, 1), (c, 3), (d, 2)\} \) be a function from \( A \) to \( B \). For \( D = \{a, c\} \), the restriction of \( f \) to \( D \) is the function \( f_1 : D \to B \) given by \( \{(a, 2), (c, 3)\} \). Sometimes, we might also consider a new codomain \( B' \) for such a restriction \( f_1 \) of \( f \). Of course, we must have range(\( f_1 \)) \subseteq \( B' \). Next, consider the function \( g : \mathbb{R} \to [0, \infty) \) defined by \( g(x) = x^2 \) for \( x \in \mathbb{R} \). Although \( g \) is onto, \( g \) is not one-to-one since \( g(1) = g(-1) = 1 \), for example. On the other hand, the restriction \( g_1 \) of \( g \) to \([0, \infty) \) is one-to-one and so the restricted function \( g_1 : [0, \infty) \to [0, \infty) \) defined by \( g_1(x) = g(x) = x^2 \) for all \( x \in [0, \infty) \) is bijective. On the other hand, if \( f : A \to B \) is a one-to-one function, then any restriction of \( f \) to a subset of \( A \) is also one-to-one.

Let \( f : A \to B \) and \( g : C \to D \) be functions, where \( A \) and \( C \) are disjoint sets. We define a function \( h \) from \( A \cup C \) to \( B \cup D \) by

\[
h(x) = \begin{cases} f(x) & \text{if } x \in A \\ g(x) & \text{if } x \in C. \end{cases}
\]

Recalling that a function is a set of ordered pairs, we see that \( h \) is the union of the two sets \( f \) and \( g \). Of course, it is essential for \( A \) and \( C \) to be disjoint in order to be guaranteed that \( h \) is a function. If \( f \) and \( g \) are onto, then \( h \) must be onto as well; however, if \( f \) and \( g \) are one-to-one, then \( h \) need not be one-to-one. The following result does provide a sufficient condition for \( h \) to be one-to-one, however.
Lemma 11.18  Let \( f : A \to B \) and \( g : C \to D \) be one-to-one functions, where \( A \cap C = \emptyset \), and where the function \( h : A \cup C \to B \cup D \) is defined by

\[
h(x) = \begin{cases} 
  f(x) & \text{if } x \in A \\
  g(x) & \text{if } x \in C.
\end{cases}
\]

If \( B \cap D = \emptyset \), then \( h \) is also a one-to-one function. Consequently, if \( f \) and \( g \) are bijective functions, then \( h \) is a bijective function.

**Proof**  Assume that \( h(x_1) = h(x_2) = y \), where \( x_1, x_2 \in A \cup B \). Then \( y \in B \cup D \). So, \( y \in B \) or \( y \in D \), say the former. Since \( B \cap D = \emptyset \), it follows that \( y \notin D \). Hence, \( x_1, x_2 \in A \) and so \( h(x_1) = f(x_1) \) and \( h(x_2) = f(x_2) \). Since \( f(x_1) = f(x_2) \) and \( f \) is one-to-one, it follows that \( x_1 = x_2 \).

Let \( A \) and \( B \) be nonempty sets such that \( B \subseteq A \) and let \( f : A \to B \). Thus, for \( x \in A \), the element \( f(x) \in B \). Since \( B \subseteq A \), it follows, of course, that \( f(x) \in A \) and so \( f(f(x)) \in B \). It is convenient to introduce some notation in this case. Let \( f^1(x) = f(x) \) and let \( f^2(x) = f(f(x)) \). In general, for an integer \( k \geq 2 \), let \( f^k(x) = f(f^{k-1}(x)) \). Hence, \( f^1(x) \), \( f^2(x) \), \( f^3(x) \), \ldots is a recursively defined sequence of elements of \( B \) (and of \( A \) as well). Thus, \( f^n(x) \) is defined for every positive integer \( n \).

For example, consider the function \( f : \mathbb{Z} \to 2\mathbb{Z} \) defined by \( f(n) = 4n \) for all \( n \in \mathbb{Z} \). Then \( f^1(3) = 3 \cdot 4 = 12 \) and \( f^2(3) = f(12) = 4 \cdot 12 = 48 \).

If \( A \) and \( B \) are nonempty sets such that \( B \subseteq A \), then the function \( \phi : B \to A \) defined by \( \phi(x) = x \) for all \( x \in B \) is injective. This gives us the expected result that \( |B| \leq |A| \). On the other hand, if there is an injective function from \( A \) to \( B \), a more interesting consequence results.

**Theorem 11.19**  Let \( A \) and \( B \) be nonempty sets such that \( B \subseteq A \). If there exists an injective function from \( A \) to \( B \), then there exists a bijective function from \( A \) to \( B \).

**Proof**  If \( B = A \), then the identity function \( i_A : A \to B = A \) is bijective. Thus, we can assume that \( B \subseteq A \) and so \( A - B \neq \emptyset \). Let \( f : A \to B \) be an injective function. If \( f \) is bijective, then the proof is complete. Therefore, we can assume that \( f \) is not onto. Hence, \( \text{range}(f) \subseteq B \) and so \( B - \text{range}(f) \neq \emptyset \).

Consider the subset \( B' \) of \( B \) defined by

\[
B' = \{ f^n(x) : x \in A - B, n \in \mathbb{N} \}.
\]

Thus, \( B' \subseteq \text{range}(f) \). Hence, for each \( x \in A - B \), its image \( f(x) \) belongs to \( B' \). Moreover, for \( x \in A - B \), the element \( f^2(x) = f(f(x)) \in B' \), \( f^3(x) = f(f^2(x)) \in B' \) and so on.

Let \( C = (A - B) \cup B' \) and consider the restriction \( f_i : C \to B' \) of \( f \) to \( C \). We show that \( f_i \) is onto. Let \( y \in B' \). Then \( y = f^n(x) \) for some \( x \in A - B \) and some \( n \in \mathbb{N} \). This implies that \( y = f(x) \) for some \( x \in A - B \) or \( y = f(x) \) for some \( x \in B' \). Therefore, \( f_i(x) = y \) for some \( x \in C \) and so \( f_i \) is onto. Furthermore, since \( f \) is one-to-one, the function \( f_i \) is also one-to-one. Hence, \( f_i : C \to B' \) is bijective.
Chapter 11  
Cardinalities of Sets

Let \( D = B - B' \). Since \( B - \text{range}(f) \neq \emptyset \) and \( B - \text{range}(f) \subseteq B - B' \), it follows that \( D \neq \emptyset \). Also, \( D \) and \( B' \) are disjoint, as are \( D \) and \( C \). Certainly, the identity function \( i_D : D \to D \) is bijective. Let \( h : C \cup D \to B' \cup D \) be defined by

\[
h(x) = \begin{cases} f_1(x) & \text{if } x \in C \\ i_D(x) & \text{if } x \in D. \end{cases}
\]

By Lemma 11.18, \( h \) is bijective. However, \( C \cup D = A \) and \( B' \cup D = B \); so \( h \) is a bijective function from \( A \) to \( B \).

From what we know of inequalities (of real numbers), it might seem that if \( A \) and \( B \) are sets with \( |A| \leq |B| \) and \( |B| \leq |A| \), then \( |A| = |B| \). This is indeed the case. This theorem is often referred to as the Schröder-Bernstein Theorem.

**Theorem 11.20** (The Schröder-Bernstein Theorem) If \( A \) and \( B \) are sets such that \( |A| \leq |B| \) and \( |B| \leq |A| \), then \( |A| = |B| \).

**Proof** Since \( |A| \leq |B| \) and \( |B| \leq |A| \), there are injective functions \( f : A \to B \) and \( g : B \to A \). Thus, \( g_1 : B \to \text{range}(g) \) defined by \( g_1(x) = g(x) \) for all \( x \in B \) is a bijective function. By Theorem 10.15, \( g_1^{-1} \) exists and \( g_1^{-1} : \text{range}(g) \to B \) is a bijective function.

Since \( f : A \to B \) and \( g_1 : B \to \text{range}(g) \) are injective functions, it follows by Theorem 10.11 that \( g_1 \circ f : A \to \text{range}(g) \) is an injective function. Because \( \text{range}(g) \subseteq A \), we have by Theorem 11.19 that there exists a bijective function \( h : A \to \text{range}(g) \). Thus, \( h : A \to \text{range}(g) \) and \( g_1^{-1} : \text{range}(g) \to B \) are bijective functions. By Corollary 10.12,

\[
g_1^{-1} \circ h : A \to B
\]

is a bijective function and \( |A| = |B| \).

The Schröder-Bernstein Theorem is referred to by some as the Cantor – Schröder-Bernstein Theorem. Although the history of this theorem has never been fully documented, there are several substantiated facts.

A mathematician who will forever be associated with the theory of sets is Georg Cantor (1845–1918). Born in Russia, Cantor studied for and obtained his Ph.D. in mathematics from the University of Berlin in 1867. In 1869 he became a faculty member at the University of Halle in Germany. It was while he was there that he became interested in set theory.

In 1873 Cantor proved that the set of rational numbers is denumerable. Shortly afterwards, he proved that the set of real numbers is uncountable. In this paper, he essentially introduced the idea of a one-to-one correspondence (bijective function). During the next several years, he made numerous contributions to set theory – studying sets of equal cardinality. There were, however, a number of problems that proved difficult for Cantor.

Consider the following two theorems:

**Theorem A** For any two cardinal numbers \( a \) and \( b \), exactly one of the following occurs: (1) \( a = b \), (2) \( a < b \), (3) \( a > b \).

**Theorem B** If \( A \) and \( B \) are two sets for which there exist a one-to-one function from \( A \) to \( B \) and a one-to-one function from \( B \) to \( A \), then \( |A| = |B| \).
Cantor observed that once Theorem A had been proved, Theorem B could be proved. On the other hand, there has never been any evidence that Cantor was able to prove Theorem A. Ernst Zermelo (1871–1953) was able to prove Theorem A in 1904. However, Zermelo’s proof made use of an axiom formulated by Zermelo. This axiom, which was controversial in the mathematical world for many years, is known as the **Axiom of Choice**.

**The Axiom of Choice.** For every collection of pairwise disjoint nonempty sets, there exists at least one set that contains exactly one element from each of these nonempty sets.

As it turned out, not only can the Axiom of Choice be used to prove Theorem A, but Theorem A is true if and only if the Axiom of Choice is true.

Ernst Schröder (1841–1902), a German mathematician, was one of the important figures in mathematical logic. During 1897–1898 Schröder presented a “proof” of Theorem B, which contained a defect however. About the same time, Felix Bernstein (1878–1956) gave his own proof of Theorem B in his doctoral dissertation, which became the first complete proof of Theorem B. His proof did not require knowledge of Theorem A.

You may be surprised to learn that \( \mathbb{R} \) and the power set of \( \mathbb{N} \) are numerically equivalent. But how could one ever find a bijective function between these two sets? Theorem 11.21 tells us that discovering such a function is unnecessary.

**Theorem 11.21**  The sets \( \mathcal{P}(\mathbb{N}) \) and \( \mathbb{R} \) are numerically equivalent.

**Proof**  First we show that there is a one-to-one function \( f : (0, 1) \rightarrow \mathcal{P}(\mathbb{N}) \). Recall that a real number \( a \in (0, 1) \) can be expressed uniquely as \( a = 0.a_1a_2a_3 \ldots \), where each \( a_i \in \{0, 1, \ldots, 9\} \) and there is no positive integer \( N \) such that \( a_n = 9 \) for all \( n \geq N \). Thus, we define \( f(a) = \{10^{n-1}a_n : n \in \mathbb{N}\} = A \).

For example, \( f(0.1234) = \{1, 20, 300, 4000\} \) and \( f(1/3) = \{3, 30, 300, \ldots\} \). We now show that \( f \) is one-to-one. Assume that \( f(a) = f(b) \), where \( a, b \in (0, 1) \) and \( a = 0.a_1a_2a_3 \ldots \) and \( b = 0.b_1b_2b_3 \ldots \) with \( a_i, b_i \in \{0, 1, \ldots, 9\} \) for each \( i \in \mathbb{N} \) such that the decimal expansion of neither \( a \) nor \( b \) is 9 from some point on. Therefore,

\[
A = \{10^{n-1}a_n : n \in \mathbb{N}\} = \{10^{n-1}b_n : n \in \mathbb{N}\} = B.
\]

Consider the \( i \)th digit, namely \( a_i \), in the decimal expansion of \( a \). Then \( 10^{i-1}a_i \in A \). If \( a_i \neq 0 \), then \( 10^{i-1}a_i \) is the unique number in the interval \([10^{i-1}, 9 \cdot 10^{i-1}]\) belonging to \( A \). Since \( A = B \), it follows that \( 10^{i-1}a_i \in B \). However, \( 10^{i-1}b_i \) is the unique number in the interval \([10^{i-1}, 9 \cdot 10^{i-1}]\) belonging to \( B \); so \( 10^{i-1}a_i = 10^{i-1}b_i \). Thus, \( a_i = b_i \). If \( a_i = 0 \), then \( 0 \in A \) and there is no number in the interval \([10^{i-1}, 9 \cdot 10^{i-1}]\) belonging to \( A \). Since \( A = B \), it follows that \( 0 \in B \) and there is no number in the interval \([10^{i-1}, 9 \cdot 10^{i-1}]\) belonging to \( B \). Thus, \( b_i = 0 \) and so \( a_i = b_i \). Hence, \( a_i = b_i \) for all \( i \in \mathbb{N} \), and so \( a = b \). Therefore, \( f \) is one-to-one and \( |(0, 1)| \leq |\mathcal{P}(\mathbb{N})| \).
Chapter 11  Cardinalities of Sets

Next we define a function \( g : \mathcal{P}(\mathbb{N}) \to (0, 1) \). For \( S \subseteq \mathbb{N} \), define \( g(S) = 0.s_1s_2s_3 \cdots \), where
\[
s_n = \begin{cases} 
1 & \text{if } n \in S \\
2 & \text{if } n \notin S.
\end{cases}
\]
Thus, \( g(S) \) is a real number in \((0, 1)\), whose decimal expansion consists only of 1s and 2s. We show that \( g \) is one-to-one. Assume that \( g(S) = g(T) \), where \( S, T \subseteq \mathbb{N} \). Thus,
\[
g(S) = s = 0.s_1s_2s_3 \cdots = 0.t_1t_2t_3 \cdots = t = g(T),
\]
where
\[
s_n = \begin{cases} 
1 & \text{if } n \in T \\
2 & \text{if } n \notin T.
\end{cases}
\]
Since the decimal expansions of \( s \) and \( t \) contain no 0s or 9s, both \( s \) and \( t \) have unique decimal expansions. We show that \( S = T \). First, we verify that \( S \subseteq T \). Let \( k \in S \). Then \( s_k = 1 \). Since \( s = t \), it follows that \( t_k = 1 \), which implies that \( k \in T \). Hence, \( S \subseteq T \). The proof that \( T \subseteq S \) is similar and is therefore omitted. Thus, \( S = T \) and \( g \) is one-to-one. Therefore, \(|\mathcal{P}(\mathbb{N})| \leq |(0, 1)|\). By the Schröder-Bernstein Theorem, \(|\mathcal{P}(\mathbb{N})| = |(0, 1)|\).

By Corollary 11.15, \(|(0, 1)| = |\mathbb{R}|\). Thus, \(|\mathcal{P}(\mathbb{N})| = |\mathbb{R}|\).

As a corollary to Theorems 11.16 and 11.21, we have the following result.

**Corollary 11.22**  The sets \( 2^\mathbb{N} \) and \( \mathbb{R} \) are numerically equivalent.

We have already mentioned that \(|A| = \aleph_0 \) for every denumerable set \( A \) and that \(|\mathbb{R}| = \mathfrak{c} \). If \( A \) is denumerable, then we represent the cardinality of the set \( 2^A \) by \( 2^{\aleph_0} \). By Corollary 11.22, \( 2^{\aleph_0} = \mathfrak{c} \).

### SECTION 11.5 EXERCISES

11.32. Prove that if \( A, B \) and \( C \) are nonempty sets such that \( A \subseteq B \subseteq C \) and \(|A| = |C|\), then \(|A| = |B|\).

11.33. Use the Schröder-Bernstein Theorem to prove that \(|(0, 1)| = |[0, 1]|\).

11.34. Prove that \(|\mathbb{Q} - \{q\}| = \aleph_0 \) for every rational number \( q \) and \(|\mathbb{R} - \{r\}| = \mathfrak{c} \) for every real number \( r \).

11.35. Let \( \mathbb{R}^* \) be the set obtained by removing the number 0 from \( \mathbb{R} \). Prove that \(|\mathbb{R}^*| = |\mathbb{R}|\).

11.36. Let \( f : \mathbb{Z} \to 2\mathbb{Z} \) be defined by \( f(k) = 4k \) for all \( k \in \mathbb{Z} \).

(a) Prove that \( f^n(k) = 4^n k \) for each \( k \in \mathbb{Z} \) and each \( n \in \mathbb{N} \).

(b) For this function \( f \), describe the sets \( B', C \) and \( D \) and functions \( f_1 \) and \( h \) given in Theorem 11.19.

11.37. Express each positive rational number as \( m/n \), where \( m, n \in \mathbb{N} \) and \( m/n \) is reduced to lowest terms. Let \( d_a \) denote the number of digits in \( a \in \mathbb{N} \). Thus, \( d_1 = 1 \), \( d_{10} = 2 \) and \( d_{100} = 3 \). Define the function \( f : \mathbb{Q}^+ \to \mathbb{N} \) so that \( f(m/n) \) is the positive integer with \( 2(d_m + d_n) \) digits whose first \( d_n \) digits is the integer \( m \), whose final \( d_n \) digits is the integer \( n \) and all of whose remaining \( d_m + d_n \) digits are 0. Thus, \( f(2/3) = 2003 \) and \( f(10/271) = 1000000271 \).

(a) Prove that \( f \) is one-to-one.

(b) Use the Schröder-Bernstein Theorem to prove that \( \mathbb{Q}^+ \) is denumerable.
Chapter 11 Supplemental Exercises

11.38. Evaluate the proposed proof of the following result.

**Result**  Let $A$ and $B$ be two sets with $|A| = |B|$. If $a \in A$ and $b \in B$, then $|A - \{a\}| = |B - \{b\}|$.

**Proof** Since $A$ and $B$ have the same number of elements and one element is removed from each of $A$ and $B$, it follows that $|A - \{a\}| = |B - \{b\}|$.

11.39. Evaluate the proposed proof of the following result.

**Result**  The sets $(0, \infty)$ and $[0, \infty)$ are numerically equivalent.

**Proof** Define the function $f : (0, \infty) \to [0, \infty)$ by $f(x) = x$. First, we show that $f$ is one-to-one. Assume that $f(a) = f(b)$. Then $a = b$ and so $f$ is one-to-one.

Next, we show that $f$ is onto. Let $r \in [0, \infty)$. Since $f(r) = r$, the function $f$ is onto. Since $f$ is bijective, $|(0, \infty)| = |[0, \infty)|$.

11.40. The **floor** $\lfloor x \rfloor$ of a real number $x$ is the greatest integer less than or equal to $x$. Therefore, $\lfloor 5.5 \rfloor = 5$, $\lfloor 3 \rfloor = 3$ and $\lfloor -5.5 \rfloor = -6$. Let $f : \mathbb{N} \to \mathbb{Z}$ be defined by $f(n) = (-1)^n \lfloor n/2 \rfloor$.

(a) Prove that $f$ is bijective.

(b) What does (a) tell us about $\mathbb{Z}$? (See Result 11.3.)

11.41. Show that the following pairs of intervals are numerically equivalent.

(a) $(0, 1)$ and $(0, \infty)$

(b) $(0, 1]$ and $[0, \infty)$

(c) $[b, c)$ and $(a, \infty)$, where $a, b, c \in \mathbb{R}$ and $b < c$.

11.42. Let $S$ and $T$ be two sets. Prove that if $|S - T| = |T - S|$, then $|S| = |T|$.

11.43. Prove each of the following statements:

(a) A nonempty set $S$ is countable if and only if there exists a surjective function $f : \mathbb{N} \to S$.

(b) A nonempty set $S$ is countable if and only if there exists an injective function $g : S \to \mathbb{N}$.

11.44. Prove that $|A| < |\mathbb{N}|$ for every finite nonempty set $A$.

11.45. Let $A = (0, 1)$ be the open interval of real numbers between 0 and 1. For each number $r \in A$, let $0.r_1r_2r_3\ldots$ denote its unique decimal expansion in which no expansion has the digit 9 from some point on. For $(a, b) \in A \times A$, let

$$f((a, b)) = f((0.a_1a_2a_3\ldots, 0.b_1b_2b_3\ldots)) = 0.a_1b_1a_2b_2\ldots;$$

while for $a \in A$, let

$$g(a) = g(0.a_1a_2a_3\ldots) = (0.a_1a_3a_5\ldots, 0.a_2a_4a_6\ldots).$$

With the aid of $f$ and $g$, which of the following are we able to conclude? Explain your answer.

(a) $|A \times A| \leq |A|$.

(b) $|A| \leq |A \times A|$.

(c) $|A \times A| = |A|$.
302 Chapter 11 Cardinalities of Sets

(d) Nothing because neither \( f : A \times A \to A \) nor \( g : A \to A \times A \) are functions.
(e) Nothing because both \( f : A \times A \to A \) and \( g : A \to A \times A \) are functions but neither is injective.
(f) Nothing, for a reason other than those given in (d) and (e).

11.46. Prove, for every integer \( n \geq 2 \), that if \( A_1, A_2, \ldots, A_n \) are denumerable sets, then \( A_1 \times A_2 \times \cdots \times A_n \) is denumerable.

11.47. As a consequence of Exercise 11.20, the set of all irrational numbers is uncountable. Among the (many) irrational numbers are \( \sqrt{2}, \sqrt{3}, \sqrt{5}, \sqrt{2}, \sqrt{3}, \sqrt{5} \) and \( \sqrt{2} \). Prove that the set \( S = \{ \sqrt{k} : k, n \in \mathbb{N} \text{ and } k, n \geq 2 \} \) is denumerable.

11.48. Let \( b, c \in \mathbb{Z} \). A number \( r_{b,c} \) (real or complex) belongs to a set \( S \) if \( r_{b,c} \) is a root of the polynomial \( x^2 + bx + c \). Prove that \( S \) is denumerable.

11.49. We have seen that \( \mathbb{R} \) is an uncountable set.

(a) Show that \( \mathbb{R} \) can be partitioned into a countable number of uncountable sets.
(b) Show that \( \mathbb{R} \) can be partitioned into an uncountable number of countable sets.

11.50. Prove that if \( A \) and \( B \) are two sets such that \( |A| = |B| \), then \( |P(A)| = |P(B)| \).

11.51. (a) Prove that the function \( f : (1, \infty) \to (0, 1) \) defined by \( f(x) = \frac{2x}{x^2+1} \) is bijective.
(b) What conclusion can be made from the result in (a)?
12

Proofs in Number Theory

We have now discussed the proof techniques that are used to verify the truth of mathematical statements. In addition, we have discussed two fundamental concepts that occur throughout mathematics, namely relations (especially equivalence relations) and functions (especially bijective functions). Where we will encounter proofs most often and where we will need a clear understanding of proof techniques is in the various areas of mathematics. This will be illustrated in the remaining chapters as we describe several basic results that occur in a number of the branches of mathematics, beginning with the area referred to as number theory.

Number theory is that area of mathematics dealing with integers and their properties. It is one of the oldest branches of mathematics, dating back at least to the Pythagoreans (500 B.C.). Number theory is considered to be one of the most beautiful branches of mathematics. Indeed, it has been said that mathematics is the queen of the sciences; while number theory is the queen of mathematics. In large measure, this subject is characterized by the appeal, clarity and simplicity of many of its problems and by the elegance and style exhibited in their solutions. The main goal of this chapter is to expand on some of the things we have learned in order to illustrate the kinds of proofs that occur in number theory.

12.1 DIVISIBILITY PROPERTIES OF INTEGERS

You may already know that every integer \( n \geq 2 \) can be expressed as a product of primes and in only one way, except for the order in which the primes are written. We will see later how to prove this fact, but first we want to return to divisibility of integers (introduced in Chapter 4) and establish several elementary divisibility properties.

Recall that a prime is an integer \( p \geq 2 \) whose only positive integer divisors are 1 and \( p \). An integer \( n \geq 2 \) that is not prime is called a composite number (or simply composite). The first ten primes are 2, 3, 5, 7, 11, 13, 17, 19, 23 and 29. The first ten composite numbers are 4, 6, 8, 9, 10, 12, 14, 15, 16 and 18. If an integer \( n \geq 2 \) is composite, then there exist integers \( a \) and \( b \) such that \( n = ab \), where \( 1 < a < n \) and \( 1 < b < n \). Certainly, if there exist integers \( a \) and \( b \) such that \( n = ab \), where \( 1 < a < n \) and \( 1 < b < n \), then \( n \) is composite. We summarize these observations in the following lemma.
Lemma 12.1  An integer \( n \geq 2 \) is composite if and only if there exist integers \( a \) and \( b \) such that \( n = ab \), where \( 1 < a < n \) and \( 1 < b < n \).

In Chapter 4, a number of basic divisibility properties were presented. We recall some of these in the following theorem, where the proofs are also repeated to review the proof techniques that we used.

Theorem 12.2  Let \( a, b \) and \( c \) be integers with \( a \neq 0 \).

(i) If \( a \mid b \), then \( a \mid bc \).

(ii) If \( a \mid b \) and \( b \mid c \), where \( b \neq 0 \), then \( a \mid c \).

(iii) If \( a \mid b \) and \( a \mid c \), then \( a \mid (bx + cy) \) for every pair \( x, y \) of integers.

Proof  We begin with part (i). Since \( a \mid b \), there exists an integer \( q \) such that \( b = aq \). Therefore, \( bc = aqc \). Since \( qc \) is an integer, \( a \mid bc \).

For part (ii), let \( a \mid b \) and \( b \mid c \). So, there exist integers \( q_1 \) and \( q_2 \) such that \( b = aq_1 \) and \( c = bq_2 \). Consequently,

\[
c = bq_2 = (aq_1)q_2 = a(q_1q_2).
\]

Since \( q_1q_2 \) is an integer, \( a \mid c \).

For part (iii), let \( a \mid b \) and \( a \mid c \). Then there exist integers \( q_1 \) and \( q_2 \) such that \( b = aq_1 \) and \( c = aq_2 \). Hence, for integers \( x \) and \( y \),

\[
bx + cy = (aq_1)x + (aq_2)y = a(q_1x + q_2y).
\]

Since \( q_1x + q_2y \) is an integer, \( a \mid (bx + cy) \).

\[\Box\]

Proof Analysis  In all three parts of the previous theorem, we were required to show that \( r \mid s \) for some integers \( r \) and \( s \), where \( r \neq 0 \). To do this, we showed that we could write \( s \) as \( rt \) for some integer \( t \). Of course, this is simply the definition of what it means for \( r \) to divide \( s \).

Proving the two parts of the next theorem relies on the definition of \( r \mid s \) again, as well as making use of certain observations. For example, in the second part, we use a fact about absolute values, namely that \( |xy| = |x||y| \) for every two real numbers \( x \) and \( y \).

Theorem 12.3  Let \( a \) and \( b \) be nonzero integers.

(i) If \( a \mid b \) and \( b \mid a \), then \( a = b \) or \( a = -b \).

(ii) If \( a \mid b \), then \( |a| \leq |b| \).

Proof  We first prove (i). Since \( a \mid b \) and \( b \mid a \), it follows that \( b = aq_1 \) and \( a = bq_2 \) for some integers \( q_1 \) and \( q_2 \). Therefore, \( a = bq_2 = (aq_1)q_2 = a(q_1q_2) \). Dividing by \( a \), we obtain \( 1 = q_1q_2 \). Hence, \( q_1 = q_2 = 1 \) or \( q_1 = q_2 = -1 \). Therefore, \( a = b \) or \( a = -b \).

Next we prove (ii). Since \( a \mid b \), it follows that \( b = aq \) for some integer \( q \). Furthermore, \( q \neq 0 \) since \( b \neq 0 \). So, \( |q| \geq 1 \). Hence,

\[
|b| = |aq| = |a| \cdot |q| \geq |a| \cdot 1 = |a|.
\]

\[\Box\]
SECTION 12.1 EXERCISES

12.1. Let \( a, b, c, d \in \mathbb{Z} \) with \( a, c \neq 0 \). Prove that if \( a \mid b \) and \( c \mid d \), then \( ac \mid (ad + bc) \).

12.2. Let \( a, b \in \mathbb{Z} \) with \( a \neq 0 \). Prove that if \( a \mid b \), then \( a \mid (-b) \) and \( (-a) \mid b \).

12.3. Let \( a, b, c \in \mathbb{Z} \) with \( a, c \neq 0 \). Prove that if \( ac \mid bc \), then \( a \mid b \).

12.4. Prove that \( 3 \mid (n^3 - n) \) for every integer \( n \).

12.5. The prime 2 can be expressed as \( 1^3 + 1 \). Prove that if \( n = k^3 + 1 \geq 3 \), where \( k \in \mathbb{Z} \), then \( n \) is not prime. That is, prove that there is only one prime that is 1 greater than a perfect cube. [Hint: Recall that \( k^3 + 1 = (k + 1)(k^2 - k + 1) \).]

12.6. Prove that there is only one prime that is 1 less than a perfect cube.

12.7. Prove that \( 8 \mid (5^2n + 7) \) for every positive integer \( n \).

12.8. Prove that \( 5 \mid (3^{n+1} + 2^{n+1}) \) for every positive integer \( n \).

12.9. Prove that for every positive integer \( n \), there exist \( n \) consecutive positive integers, each of which is composite. [Hint: Consider the numbers \( 2 + (n + 1)!; 3 + (n + 1)!; \ldots; n + (n + 1)!; n + 1 + (n + 1)! \).]

12.10. (a) Prove that \( 6 \mid (5n^3 + 7n) \) for every positive integer \( n \).

(b) Observe that \( 5 + 7 = 12 \) is a multiple of 6. State and prove a generalization of the problem in (a).

12.11. Prove the following: Let \( d \) be a nonzero integer. If \( a_1, a_2, \ldots, a_n \) and \( x_1, x_2, \ldots, x_n \) are \( 2n \geq 2 \) integers such that \( d \mid a_i \) for all \( i \leq i \leq n \), then \( d \mid \sum_{i=1}^{n} a_ix_i \).

12.12. Let \( p_n \) denote the \( n \)th prime and \( c_n \) the \( n \)th composite number. Thus, \( p_1 = 2 \) and \( p_2 = 3 \), while \( c_1 = 4 \) and \( c_2 = 6 \). Of course, \( p_n \neq c_n \) for all \( n \in \mathbb{N} \). Determine all positive integers \( n \) such that \( |p_n - c_n| = 1 \).

12.13. (a) Suppose that there are \( k \) distinct positive integers that divide an odd positive integer \( n \). How many distinct positive integers divide \( 2n \)? How many divide \( 4n \)?

(b) Suppose that there are \( k \) distinct positive integers that divide a positive integer \( n \) that is not divisible by 3. How many distinct positive integers divide \( 3n \)? How many divide \( 9n \)?

(c) State and answer a question suggested by the questions in (a) and (b).

12.14. For an integer \( n \geq 2 \), let \( m \) be the largest positive integer less than \( n \) such that \( m \mid n \). Then \( n = mk \) for some positive integer \( k \). Prove that \( k \) is a prime.

12.2 THE DIVISION ALGORITHM

We have discussed the concept of divisibility a number of times now. Of course, when we use that term, we are referring to the statement \( a \mid b \), where \( a, b \in \mathbb{Z} \) and \( a \neq 0 \). Surely, the term division is more familiar to us. For positive integers \( a \) and \( b \), it is an elementary problem to divide \( b \) by \( a \) and ask for the quotient \( q \) and remainder \( r \). For example, for \( a = 5 \) and \( b = 17 \), we have \( q = 3 \) and \( r = 2 \); that is, if 17 is divided by 5, a quotient of 3 and a remainder of 2 result. This division can be expressed as \( 17 = 5 \cdot 3 + 2 \). If \( a = 6 \) and \( b = 42 \), then \( q = 7 \) and \( r = 0 \); so \( 42 = 6 \cdot 7 + 0 \) or \( 6 \mid 42 \).

More generally, for positive integers \( a \) and \( b \), it is always possible to write \( b = aq + r \), where \( 0 \leq r < a \). The number \( q \) is the quotient and \( r \) is the remainder when \( b \) is divided by \( a \). In fact, not only do the integers \( q \) and \( r \) exist, they are unique. This is the
The essence of a theorem called the **Division Algorithm**. Although this theorem may seem rather obvious because you’ve probably used it so often, it is important and its proof is not all that obvious.

**Theorem to Prove**

(The Division Algorithm): For positive integers \(a\) and \(b\), there exist unique integers \(q\) and \(r\) such that \(b = aq + r\) and \(0 \leq r < a\).

**Proof Strategy**

We start the proof then with two positive integers \(a\) and \(b\). We have two problems facing us. First, we need to show that there are integers \(q\) and \(r\) such that \(b = aq + r\) and \(0 \leq r < a\). Second, we must show that only one integer \(q\) and only one integer \(r\) satisfy the equation \(b = aq + r\) and inequality \(0 \leq r < a\). How can we come up with integers \(q\) and \(r\) satisfying these conditions? Our main concern, as it turns out, is showing that there exist integers \(q\) and \(r\) such that \(b = aq + r\) and \(0 \leq r < a\).

If \(a | b\), then we know that \(b = aq\) for some integer \(q\). So \(b = aq + 0\) and \(r = 0\) satisfies \(0 \leq r < a\). If \(a \nmid b\), then \(b \neq aq\) for every integer \(q\) and so \(b - aq \neq 0\) for every integer \(q\). However, when we perform the operation of dividing \(b\) by \(a\), we obtain a quotient \(q\) and a nonzero remainder \(r\). The integer \(q\) has the properties that \(b - aq > 0\) and \(b - aq\) is as small as possible. Whether \(a | b\) or \(a \nmid b\), this suggests considering the set

\[
S = \{b - ax : x \in \mathbb{Z} \text{ and } b - ax \geq 0\},
\]

which is a set of nonnegative integers. Once we show that \(S \neq \emptyset\), we can apply Theorem 6.7 (which states, for every integer \(m\), that the set \(\{i \in \mathbb{Z} : i \geq m\}\) is well-ordered) to conclude that \(S\) has a smallest element \(r\), which means that there is an integer \(q\) such that \(b - aq = r\). So \(b = aq + r\) and we have the beginning of a proof.

**Theorem 12.4** (The Division Algorithm) For positive integers \(a\) and \(b\), there exist unique integers \(q\) and \(r\) such that \(b = aq + r\) and \(0 \leq r < a\).

**Proof**

First we show that there exist integers \(q\) and \(r\) such that \(b = aq + r\) with \(0 \leq r < a\). We will verify the uniqueness later. Consider the set

\[
S = \{b - ax : x \in \mathbb{Z} \text{ and } b - ax \geq 0\}.
\]

By letting \(x = 0\), we see that \(b \in S\) and \(S\) is nonempty. Therefore, by Theorem 6.7, \(S\) has a smallest element \(r\) and, necessarily, \(r \geq 0\). Also, since \(r \in S\), there is some integer \(q\) such that \(r = b - aq\). Thus, \(b = aq + r\) with \(r \geq 0\).

Next we show that \(r < a\). Assume, to the contrary, that \(r \geq a\). Let \(t = r - a\). Then \(t \geq 0\). Since \(a = r - t\) and \(a > 0\), it follows that \(t < r\). Moreover,

\[
t = r - a = (b - aq) - a = b - (aq + a) = b - a(q + 1),
\]

which implies that \(t \in S\), contradicting the fact that \(r\) is the smallest element of \(S\). Therefore \(r < a\), as desired.

It remains to show that \(q\) and \(r\) are the only integers for which \(b = aq + r\) and \(0 \leq r < a\). Let \(q'\) and \(r'\) be integers such that \(b = aq' + r'\), where \(0 \leq r' < a\). We show
that \( q = q' \) and \( r = r' \). Assume, without loss of generality, that \( r' \geq r \); \( r' - r \geq 0 \). Since \( aq + r = aq' + r' \), it follows that

\[
(aq - q') = r' - r.
\]

Since \( q - q' \) is an integer, \( a | (r' - r) \). Because \( 0 \leq r' - r < a \), we must have \( r' - r = 0 \) and so \( r' = r \). However, \( a(q - q') = r' - r = 0 \) and \( a \neq 0 \); so \( q - q' = 0 \) and \( q = q' \).

In Theorem 12.4 we restricted \( a \) and \( b \) to be positive. With minor modification in the proof, we can remove these restrictions, although, of course, we must still require that \( a \neq 0 \). Exercise 12.20 asks for a proof of the following result.

**Corollary 12.5** (The Division Algorithm, General Form) For integers \( a \) and \( b \) with \( a \neq 0 \), there exist unique integers \( q \) and \( r \) such that \( b = aq + r \) and \( 0 \leq r < |a| \).

The proof of Theorem 12.4 is an existence proof since it establishes the existence of the integers \( q \) and \( r \) but does not provide a method for finding \( q \) and \( r \). However, there is an implicit connection between the proof of the theorem and the manner in which you were taught to divide one positive integer by another to find the quotient and remainder (as we mentioned earlier). For instance, when dividing 89 by 14 you first determine the number of times 14 goes into 89, namely 6. More formally, you found the largest nonnegative integer whose product with 14 does not exceed 89. This number is 6. You then subtract \( 14 \cdot 6 = 84 \) from 89 to find the remainder 5. This determines the least nonnegative value of \( 89 - 14q \), where \( q \) is an integer, which corresponds to the least nonnegative value of the set \( S \) for \( a = 14 \) and \( b = 89 \) in the proof of Theorem 12.4.

**Example 12.6** Consistent with the notation of Corollary 12.5, find the integers \( q \) and \( r \) for the given integers \( a \) and \( b \).

\[(i) \quad a = 17, \ b = 78 \]
\[(ii) \quad a = -17, \ b = 78 \]
\[(iii) \quad a = 17, \ b = -78 \]
\[(iv) \quad a = -17, \ b = -78 \]

**Solution** (i) By simple division, we see that dividing 78 by 17 results in a quotient of 4 and a remainder of 10, that is,

\[
78 = 17 \cdot 4 + 10; \quad (12.1)
\]

so, \( q = 4 \) and \( r = 10 \).

(ii) By replacing 17 and 4 in (12.1) by \(-17\) and \(-4\), respectively, we obtain

\[
78 = (-17)(-4) + 10; \quad (12.2)
\]

so, \( q = -4 \) and \( r = 10 \).

(iii) Multiplying (12.1) through by -1, we have

\[
-78 = -(17 \cdot 4) + (-10) = 17(-4) + (-10). \quad (12.2)
\]

Since every remainder is nonnegative, we subtract 17 from and add 17 to the right side of (12.2), producing

\[
-78 = 17(-5) + 7; \quad (12.3)
\]
308  Chapter 12  Proofs in Number Theory

so, \( q = -5 \) and \( r = 7 \).

(iv) If, in (12.3), we replace \( 17 \) and \(-5\) by \(-17\) and \(5\), respectively, we have

\[ -78 = (-17) \cdot 5 + 7; \]

so, \( q = 5 \) and \( r = 7 \).

We now discuss some consequences of the Division Algorithm. If this algorithm is applied to an arbitrary integer \( b \) when \( a = 2 \), then we see that \( b \) must have one of the two forms \( 2q \) or \( 2q + 1 \) (according to whether \( r = 0 \) or \( r = 1 \)). Of course, if \( b = 2q \), then \( b \) is even; while if \( b = 2q + 1 \), then \( b \) is odd. We have seen this earlier and often. This, of course, shows that every integer is either even or odd.

If we apply the Division Algorithm to an arbitrary integer \( b \) when \( a = 3 \), then \( b \) has exactly one of the three forms \( 3q \), \( 3q + 1 \) or \( 3q + 2 \) (according to whether \( r = 0 \), \( r = 1 \), \( r = 2 \)). We saw this earlier as well in Chapter 4. In general, for an arbitrary integer \( b \) and arbitrary positive integer \( a \), the remainder \( r \) is one of the integers \( 0 \), \( 1 \), \( 2 \), ..., \( a - 1 \). Hence, \( b \) is expressible as exactly one of \( aq \), \( aq + 1 \), ..., \( aq + (a - 1) \).

This last remark should also sound familiar. In Chapter 9 we considered, for an integer \( n \geq 2 \), a relation \( R \) defined on \( \mathbb{Z} \) by \( aRb \) if \( a \equiv b \pmod{n} \), that is, if \( n \mid (a - b) \). This relation was found to be an equivalence relation and the set

\[ \mathbb{Z}_n = \{[0], [1], \ldots, [n - 1]\} \]

of distinct equivalence classes was referred to as the set of integers modulo \( n \). With the aid of the Division Algorithm, we now take a closer look at this relation.

For each integer \( b \), there exist, by the Division Algorithm, unique integers \( q \) and \( r \) such that \( b = nq + r \), where \( 0 \leq r < n \). Thus, \( b - r = nq \) and \( n \mid (b - r) \); so \( b \equiv r \pmod{n} \). Since \( b \equiv r \pmod{n} \), it follows that \( b \in [r] \). However, since \( r \) is the unique integer with \( 0 \leq r \leq n - 1 \), we see that \( b \) belongs to exactly one of the classes \( [0] \), \( [1] \), ..., \( [n - 1] \). These observations show that

(i) the classes \( [0] \), \( [1] \), ..., \( [n - 1] \) are pairwise disjoint and
(ii) \( \mathbb{Z} = [0] \cup [1] \cup \cdots \cup [n - 1] \),

neither of which should seem surprising once we recall that the equivalence classes always produce a partition of the set on which the equivalence relation is defined. Furthermore, for each \( r = 0, 1, \ldots, n - 1 \),

\[ [r] = \{nq + r : q \in \mathbb{Z}\} ; \]

that is, \([r]\) consists of all those integers having a remainder of \( r \) when divided by \( n \). For this reason, these equivalence classes were also referred to as residue classes modulo \( n \).

The special case where \( n = 3 \) was considered in Chapter 9 and the resulting residue classes were exhibited. In the present context, these residue classes are

\[ [0] = \{3q : q \in \mathbb{Z}\} = \{\ldots, -6, -3, 0, 3, 6, \ldots\} \]
\[ [1] = \{3q + 1 : q \in \mathbb{Z}\} = \{\ldots, -5, -2, 1, 4, \ldots\} \]
\[ [2] = \{3q + 2 : q \in \mathbb{Z}\} = \{\ldots, -4, -1, 2, 5, \ldots\} . \]
SECTION 12.2 EXERCISES

12.15. Illustrate the Division Algorithm for:
(a) \( a = 17, b = 125 \)  
(b) \( a = -17, b = 125 \)  
(c) \( a = 8, b = 96 \)  
(d) \( a = -8, b = 96 \)  
(e) \( a = 22, b = -17 \)  
(f) \( a = -22, b = -17 \)  
(g) \( a = 15, b = 0 \)  
(h) \( a = -15, b = 0 \).

12.16. Give an example of a prime \( p \) of each of the forms:
(a) \( 4k + 1 \)  
(b) \( 4k + 3 \)  
(c) \( 6k + 1 \)  
(d) \( 6k + 5 \).

12.17. Let \( p \) be an odd prime. Prove each of the following.
(a) \( p \) is of the form \( 4k + 1 \) or of the form \( 4k + 3 \) for some nonnegative integer \( k \).
(b) \( p \geq 5 \) is of the form \( 6k + 1 \) or of the form \( 6k + 5 \) for some nonnegative integer \( k \).

12.18. Show that, except for 2 and 5, every prime can be expressed as \( 10k + 1 \), \( 10k + 3 \), \( 10k + 7 \) or \( 10k + 9 \), where \( k \in \mathbb{Z} \).

12.19. (a) Prove that if an integer \( n \) has the form \( 6q + 5 \) for some \( q \in \mathbb{Z} \), then \( n \) has the form \( 3k + 2 \) for some \( k \in \mathbb{Z} \).
(b) Is the converse of (a) true?

12.20. Prove the General Form of the Division Algorithm (Corollary 12.5): For integers \( a \) and \( b \) with \( a \neq 0 \), there exist unique integers \( q \) and \( r \) such that \( b = aq + r \) and \( 0 \leq r < |a| \).

12.21. Prove that the square of every odd integer is of the form \( 4k + 1 \), where \( k \in \mathbb{Z} \)(that is, for each odd integer \( a \in \mathbb{Z} \), there exists \( k \in \mathbb{Z} \) such that \( a^2 = 4k + 1 \)).

12.22. (a) Prove that the square of every integer that is not a multiple of 3 is of the form \( 3k + 1 \), where \( k \in \mathbb{Z} \).
(b) Prove that the square of no integer is of the form \( 3m - 1 \), where \( m \in \mathbb{Z} \).

12.23. Complete the following statement in a best possible manner and give a proof. (See Exercise 12.22(a).) The square of an integer that is not a multiple of 5 is either of the form \(__ \) or \(__ \).

12.24. (a) Prove that for every integer \( m \), one of the integers \( m, m+4, m+8, m+12, m+16 \) is a multiple of 5.
(b) State and prove a generalization of the result in (a).

12.25. Prove that if \( a_1, a_2, \ldots, a_n \) are \( n \geq 2 \) integers such that \( a_i \equiv 1 \pmod{3} \) for every integer \( i \) (\( 1 \leq i \leq n \)), then \( a_1a_2 \cdots a_n \equiv 1 \pmod{3} \).

12.26. Let \( a, b \) and \( c \) be integers. Prove that if \( abc \equiv 1 \pmod{3} \), then an odd number of \( a, b \) and \( c \) are congruent to 1 modulo 3.

12.27. Prove or disprove: If \( a \) and \( b \) are odd integers, then \( 4 \mid (a - b) \) or \( 4 \mid (a + b) \).

12.28. Prove for every positive integer \( n \) that \( n^2 + 1 \) is not a multiple of 6.

12.29. It is known that there are infinitely many positive integers whose square is the sum of the squares of two positive integers. For example, \( 5^2 = 3^2 + 4^2 \) and \( 13^2 = 5^2 + 12^2 \).
(a) Prove that there are infinitely many positive integers whose square is the sum of the squares of three positive integers. For example, \( 59^2 = 50^2 + 30^2 + 9^2 \).
(b) Prove that there are infinitely many positive integers whose square is the sum of the squares of four positive integers.

12.30. (a) Let \( n \in \mathbb{N} \). Show that for every set \( S \) of \( n \) distinct integers, there is a nonempty subset \( T \) of \( S \) such that \( n \) divides the sum of the elements of \( T \). [Hint: Let \( S = \{a_1, a_2, \ldots, a_n\} \) and consider the subsets \( S_k = \{a_1, a_2, \ldots, a_k\} \) for each \( 1 \leq k \leq n \).]
(b) Is the word “distinct” necessary in (a)?
310 Chapter 12 Proofs in Number Theory

12.31. For an integer \( n \geq 2 \), let \( S_n \) be the set of all positive integers \( m \) for which \( n \) is the smallest positive integer such that when \( m \) is divided by \( n \), the remainder 1 results.

(a) What does \( S_2 \) consist of?
(b) To which set \( S_n \) does 14 belong?
(c) To which set \( S_n \) does 16 belong?
(d) Prove or disprove: For each integer \( n \geq 2 \), the set \( S_n \) either contains infinitely many elements or is empty.

12.3 GREATEST COMMON DIVISORS

We now move from the divisors of an integer to the divisors of a pair of integers. An integer \( c \neq 0 \) is a common divisor of two integers \( a \) and \( b \) if \( c \mid a \) and \( c \mid b \). We are primarily interested in the largest integer that is a common divisor of \( a \) and \( b \). Formally, the greatest common divisor of two integers \( a \) and \( b \), not both 0, is the greatest positive integer that is a common divisor of \( a \) and \( b \). The requirement that \( a \) and \( b \) are not both 0 is needed since every positive integer divides 0. We denote the greatest common divisor of two integers \( a \) and \( b \) by \( \gcd(a, b) \), although \( (a, b) \) is common notation as well.

If \( a \) and \( b \) are relatively small (in absolute value), it is normally easy to determine \( \gcd(a, b) \). For example, it should be clear that \( \gcd(8, 12) = 4 \), \( \gcd(4, 9) = 1 \) and \( \gcd(18, 54) = 18 \). The definition of \( \gcd(a, b) \) does not require \( a \) and \( b \) to be positive; indeed, it only requires at least one of \( a \) and \( b \) to be nonzero. For example, \( \gcd(-10, -15) = 5 \), \( \gcd(16, -72) = 8 \) and \( \gcd(0, -9) = 9 \).

There are two useful properties of the greatest common divisor of two integers, particularly from a theoretical point of view, that we want to mention. For integers \( a \) and \( b \), an integer of the form \( ax + by \), where \( x, y \in \mathbb{Z} \), is called a linear combination of \( a \) and \( b \). Using this terminology, we can now restate Theorem 12.2(iii): Every nonzero integer that divides two integers \( b \) and \( c \) divides every linear combination of \( b \) and \( c \). Although there appears to be no apparent connection between linear combinations of \( a \) and \( b \) and \( \gcd(a, b) \), we are about to see that there is, in fact, a very close connection. For example, let \( a = 10 \) and \( b = 16 \). Then 6, \(-4\) and 0 are all linear combinations of \( a \) and \( b \) since, for example,

\[
6 = 10 \cdot (-1) + 16 \cdot (1), \quad -4 = 10 \cdot (-2) + 16 \cdot (1) \quad \text{and} \quad 0 = 10 \cdot 0 + 16 \cdot 0.
\]

The integer 4 is also a linear combination of \( a \) and \( b \) since 4 = 10(2) + 16(-1). Furthermore, 2 is a linear combination of \( a \) and \( b \) since 2 = 10(-3) + 16(2). On the other hand, no odd integer can be a linear combination of \( a \) and \( b \) since if \( n \) is a linear combination of \( a \) and \( b \), then there exist integers \( x \) and \( y \) such that

\[ n = ax + by = 10x + 16y = 2(5x + 8y). \]

Since \( 5x + 8y \) is an integer, \( n \) is even. Consequently, 2 is the least positive integer that is a linear combination of 10 and 16. Curiously enough, \( \gcd(10, 16) = 2 \). We now show that this observation is no coincidence. Again, the Well-Ordering Principle will prove to be useful.
Theorem 12.7  Let $a$ and $b$ be integers that are not both 0. Then $\gcd(a, b)$ is the least positive integer that is a linear combination of $a$ and $b$.

Proof  Let $S$ denote the set of all positive integers that are linear combinations of $a$ and $b$, that is,

$$S = \{ax + by : x, y \in \mathbb{Z} \text{ and } ax + by > 0\}.$$ 

First we show that $S$ is nonempty. By assumption, at least one of $a$ and $b$ is nonzero; so $a \cdot a + b \cdot b = a^2 + b^2 > 0$. Thus, $a \cdot a + b \cdot b \in S$ and, as claimed, $S \neq \emptyset$.

Since $S$ is a nonempty subset of $\mathbb{N}$, it follows by the Well-Ordering Principle that $S$ contains a least element, which we denote by $d$. Thus, there exist integers $x_0$ and $y_0$ such that $d = ax_0 + by_0$. We now show that $d = \gcd(a, b)$. Applying the Division Algorithm when $a$ is divided by $d$, we have $a = dq + r$, where $0 \leq r < d$. Consequently,

$$r = a - dq = a - q(ax_0 + by_0) = a(1 - qx_0) + b(-qy_0),$$

that is, $r$ is a linear combination of $a$ and $b$. If $0 < r < d$, then necessarily $r \in S$, which would contradict the fact that $d$ is the least element in $S$. Therefore $r = 0$, which implies that $d \mid a$. By a similar argument, it follows that $d \mid b$ and so $d$ is a common divisor of $a$ and $b$.

It remains to show that $d$ is the greatest common divisor of $a$ and $b$. Let $c$ be a positive integer that is also a common divisor of $a$ and $b$. By Theorem 12.2 (iii), $c$ divides every linear combination of $a$ and $b$ and so $c$ divides $d = ax_0 + by_0$. Because $c$ and $d$ are positive and $c \mid d$, it follows that $c \leq d$ and therefore $d = \gcd(a, b)$.

PROOF ANALYSIS  The proof of Theorem 12.7 illustrates a common proof technique involving divisibility of integers. At one point of the proof, we wanted to show that $d \mid a$. A common method used to show that one integer $d$ divides another integer $a$ is to apply the Division Algorithm and divide $a$ by $d$, obtaining $a = dq + r$, where $0 \leq r < |d|$ or, if $d > 0$, then $0 \leq r < d$. The goal then is to show that $r = 0$.

There is another characterization of the greatest common divisor of two integers, not both 0, that is useful to know. This characterization provides an alternative definition of the greatest common divisor, which, in fact, is used as the definition on occasion.

Theorem 12.8  Let $a$ and $b$ be two integers, not both 0. Then $d = \gcd(a, b)$ if and only if $d$ is a positive integer which satisfies the following two conditions:

1. $d$ is a common divisor of $a$ and $b$;
2. if $c$ is any common divisor of $a$ and $b$, then $c \mid d$.

Proof  First, assume that $d = \gcd(a, b)$. We show that $d$ satisfies (1) and (2). By definition, $d$ satisfies (1); so it only remains to show that $d$ satisfies (2). Let $c$ be an integer such that $c \mid a$ and $c \mid b$. Since $d = \gcd(a, b)$, there exist integers $x_0$ and $y_0$ such that $d = ax_0 + by_0$. Since $c \mid a$ and $c \mid b$, it follows by Theorem 12.2 (iii) that $c$ divides $ax_0 + by_0 = d$. Therefore, $d$ satisfies (2).

For the converse, assume that $d$ is a positive integer satisfying properties (1) and (2). We show that $d = \gcd(a, b)$. Since $d$ is already a common divisor of $a$ and $b$, it suffices
to show that $d$ is the greatest common divisor of $a$ and $b$. Let $c$ be any positive integer that is a common divisor of $a$ and $b$. Since $d$ satisfies (2), $c \mid d$. Since $c$ and $d$ are both positive, it follows by Theorem 12.3(ii) that $c \leq d$, which implies that $d = \gcd(a, b)$. ■

SECTION 12.3 EXERCISES

12.32. Give an example of a set $S$ of four (distinct) positive integers such that the greatest common divisor of all six pairs of elements of $S$ is 6.

12.33. Give an example of a set $S$ of four (distinct) positive integers such that the greatest common divisors of all six pairs of elements of $S$ are six distinct positive integers.

12.34. Prove for $a \in \mathbb{Z}$ and $n \in \mathbb{N}$ that $\gcd(a, a + n) \mid n$.

12.35. Let $a$ and $b$ be two integers, not both 0, where $\gcd(a, b) = d$. Prove for a positive integer $k$ that $\gcd(ka, kb) = kd$.

12.36. For positive integers $a$, $b$ and $c$, the greatest common divisor $\gcd(a, b, c)$ of $a$, $b$ and $c$ is the largest positive integer that divides all of $a$, $b$ and $c$. Let $d = \gcd(a, b, c)$, $e = \gcd(a, b)$ and $f = \gcd(e, c)$. Prove that $d = f$.

12.4 THE EUCLIDEAN ALGORITHM

Although we know the definition of the greatest common divisor $d$ of two integers $a$ and $b$, not both 0, and two characterizations, none of these is especially useful in computing $d$. For this reason, we describe an algorithm for determining $d = \gcd(a, b)$ that is attributed to the famous mathematician Euclid, best known for his work in geometry. First we note that if $b = 0$, then $a \neq 0$ and $\gcd(a, b) = \gcd(a, 0) = |a|$. Hence, we may assume that $a$ and $b$ are nonzero. Furthermore, since $\gcd(a, b) = \gcd(a, -b) = \gcd(-a, b) = \gcd(-a, -b)$, we can assume that $a$ and $b$ are both positive. In general then, we may assume that $0 < a \leq b$. The procedure for computing $d = \gcd(a, b)$, which we are about to describe and which is called the Euclidean Algorithm, makes use of repeated applications of the Division Algorithm and the following lemma.

**Lemma 12.9** Let $a$ and $b$ be positive integers. If $b = aq + r$ for some integers $q$ and $r$, then $\gcd(a, b) = \gcd(r, a)$.

**Proof** Let $d = \gcd(a, b)$ and $e = \gcd(r, a)$. We show that $d = e$. First note that $b = aq + r = aq + r \cdot 1$, that is, $b$ is a linear combination of $a$ and $r$. Since $e = \gcd(r, a)$, it follows that $e \mid a$ and $e \mid r$. By Theorem 12.2(iii), $e \mid (aq + r \cdot 1)$ and so $e \mid b$. Hence, $e$ is a common divisor of $a$ and $b$. Because $d = \gcd(a, b)$, we have $e \leq d$.

Since $b = aq + r$, we can write $r = b - aq = b \cdot 1 + a(-q)$, and so $r$ is a linear combination of $a$ and $b$. From the fact that $d = \gcd(a, b)$, we obtain $d \mid (b \cdot 1 + a(-q))$; that is, $d \mid r$. So, $d$ is a common divisor of $r$ and $a$. Since $e = \gcd(r, a)$, it follows that $d \leq e$. Thus, $e = d$. ■

We are now prepared to describe the Euclidean Algorithm. We begin with two integers $a$ and $b$, where $0 < a \leq b$. By the Division Algorithm,

$$b = aq_1 + r_1, \text{ where } 0 \leq r_1 < a.$$
By Lemma 12.9, \( \gcd(a, b) = \gcd(r_1, a) \). So, if \( r_1 = 0 \), then \( \gcd(a, b) = \gcd(0, a) = a \). Hence, we may assume that \( r_1 \neq 0 \) and apply the Division Algorithm to \( r_1 \) and \( a \), obtaining
\[
a = r_1q_2 + r_2, \quad \text{where } 0 \leq r_2 < r_1.
\]
At this point, we have \( \gcd(a, b) = \gcd(r_1, a) = \gcd(r_2, r_1) \) and \( 0 \leq r_2 < r_1 < a \). If \( r_2 = 0 \), then \( \gcd(a, b) = \gcd(r_1, a) = \gcd(0, r_1) = r_1 \). By now, we should see the usefulness of Lemma 12.9 and also what we mean by repeated applications of the Division Algorithm. We continue this process and obtain the following sequence of equalities and inequalities:
\[
\begin{align*}
b &= aq_1 + r_1 & 0 < r_1 < a \\
a &= r_1q_2 + r_2 & 0 \leq r_2 < r_1 \\
&\vdots & \vdots \\
r_{k-1} &= r_kq_{k+1} + r_{k+1} & 0 \leq r_{k+1} < r_k \\
&\vdots & \vdots 
\end{align*}
\]
By Lemma 12.9,
\[
\gcd(a, b) = \gcd(r_1, a) = \gcd(r_2, r_1) = \cdots = \gcd(r_{k+1}, r_k) = \cdots
\]
and \( \cdots < r_{k+1} < r_k < \cdots < r_2 < r_1 < a \). Since these remainders are nonnegative, the strictly decreasing sequence \( r_1, r_2, \ldots \) of remainders contains at most \( a \) terms. Let \( r_{n-1} \) be the last nonzero remainder. Thus, \( r_n = 0 \). We then have:
\[
\begin{align*}
b &= aq_1 + r_1 & 0 \leq r_1 < a \\
a &= r_1q_2 + r_2 & 0 \leq r_2 < r_1 \\
&\vdots & \vdots \\
r_{n-4} &= r_{n-3}q_{n-2} + r_{n-2} & 0 \leq r_{n-2} < r_{n-3} \\
r_{n-3} &= r_{n-2}q_{n-1} + r_{n-1} & 0 \leq r_{n-1} < r_{n-2} \\
r_{n-2} &= r_{n-1}q_n + 0
\end{align*}
\]
and we know that
\[
\gcd(a, b) = \gcd(r_1, a) = \gcd(r_2, r_1) = \cdots = \gcd(r_{n-1}, r_{n-2}) = \gcd(0, r_{n-1}) = r_{n-1}.
\]
The Euclidean Algorithm can now be described. We start with two integers \( a \) and \( b \), where \( 0 < a \leq b \). If \( a \mid b \), then \( \gcd(a, b) = a \); while if \( a \nmid b \), then we apply the Division Algorithm repeatedly until a remainder of 0 is obtained. In this latter case, the last nonzero remainder is then \( \gcd(a, b) \).

Let’s see how the Euclidean Algorithm works in practice.

**Example 12.10**  Use the Euclidean Algorithm to determine \( d = \gcd(374, 946) \).

**Solution**  Dividing 946 by 374, we find that
\[
946 = 374 \cdot 2 + 198.
\]
Now, dividing 374 by 198, we have
\[
374 = 198 \cdot 1 + 176.
\]
Chapter 12  Proofs in Number Theory

Continuing in this manner, we obtain

\[
\begin{align*}
198 &= 176 \cdot 1 + 22 \\
176 &= 22 \cdot 8 + 0.
\end{align*}
\]

So \(\gcd(374, 946) = 22\).

Given integers \(a\) and \(b\), not both 0, we know that there exist integers \(s\) and \(t\) such that

\[
\gcd(a, b) = as + bt.
\]

We now describe an algorithm for finding such integers \(s\) and \(t\), using the notation in the calculations done after the proof of Lemma 12.9. Since \(\gcd(a, b) = r_{n-1}\), our goal is to find integers \(s\) and \(t\) such that

\[
r_{n-1} = r_{n-3} - r_{n-2}q_{n-1}.
\]

(12.5)

Next, using equations (12.4), we solve for \(r_{n-2}\), obtaining

\[
r_{n-2} = r_{n-4} - r_{n-3}q_{n-2}.
\]

Now substituting this expression for \(r_{n-2}\) into equation (12.5), we obtain

\[
r_{n-1} = r_{n-3} - q_{n-1}(r_{n-4} - r_{n-3}q_{n-2})
\]

\[
= (1 + q_{n-1}q_{n-2})r_{n-3} + (-q_{n-1})r_{n-4}.
\]

At this point, \(r_{n-1}\) is represented as a linear combination of \(r_{n-3}\) and \(r_{n-4}\). Notice that \(r_{n-2}\) no longer appears in the expression. As we continue with this backward substitution method, we eliminate the remainders \(r_{n-3}, r_{n-4}, \ldots, r_2, r_1\) one at a time and eventually arrive at an equation of the form \(r_{n-1} = as + bt\).

Example 12.11  For \(a = 374\) and \(b = 946\), find integers \(s\) and \(t\) such that \(as + bt = \gcd(a, b)\).

Solution  Using the computations from Example 12.10, we have

\[
\begin{align*}
22 &= 198 - 176 \cdot 1 = 198 \cdot 1 + 176 \cdot (-1) \\
176 &= 374 - 198 \cdot 1 = 374 \cdot 1 + 198 \cdot (-1) \\
198 &= 946 - 374 \cdot 2 = 946 \cdot 1 + 374 \cdot (-2).
\end{align*}
\]

Therefore,

\[
\begin{align*}
22 &= 198 \cdot 1 + 176 \cdot (-1) \\
&= 198 \cdot 1 + [374 \cdot 1 + 198 \cdot (-1)] \cdot (-1) \\
&= 198 \cdot 1 + 374 \cdot (-1) + 198 \cdot 1 \\
&= 198 \cdot 2 + 374 \cdot (-1) \\
&= [946 \cdot 1 + 374 \cdot (-2)] \cdot 2 + 374 \cdot (-1) \\
&= 946 \cdot 2 + 374 \cdot (-4) + 374 \cdot (-1) \\
&= 946 \cdot 2 + 374 \cdot (-5).
\end{align*}
\]

Hence, \(s = -5\) and \(t = 2\).
The integers \( s \) and \( t \) that we have just found are not unique. Indeed, if \( \gcd(a, b) = d \) and \( d = as + bt \), then \( d = a(s + b) + b(t - a) \) as well.

## SECTION 12.4 EXERCISES

12.37. Use the Euclidean Algorithm to find the greatest common divisor for each of the following pairs of integers:
   (a) 51 and 288  (b) 357 and 629  (c) 180 and 252.

12.38. Determine integers \( x \) and \( y \) such that (see Exercise 12.37):
   (a) \( \gcd(51, 288) = 51x + 288y \)
   (b) \( \gcd(357, 629) = 357x + 629y \)
   (c) \( \gcd(180, 252) = 180x + 252y \).

12.39. Let \( a \) and \( b \) be integers, not both 0. Show that there are infinitely many pairs \( s, t \) of integers such that \( \gcd(a, b) = as + bt \).

12.40. Let \( a, b \in \mathbb{Z} \), where not both \( a \) and \( b \) are 0, and let \( d = \gcd(a, b) \). Show that \( n \) is a linear combination of \( a \) and \( b \) if and only if \( d \mid n \).

12.41. An integer \( n > 1 \) has the properties that \( n \mid (35m + 26) \) and \( n \mid (7m + 3) \) for some integer \( m \). What is \( n \)?

12.42. Let \( a, b \in \mathbb{Z} \), where not both \( a \) and \( b \) are 0. Prove that if \( d = \gcd(a, b) \), \( a = a_1d \) and \( b = b_1d \), then \( \gcd(a_1, b_1) = 1 \).

12.43. Prove the following: Let \( a, b, c, m, n \in \mathbb{Z} \), where \( m, n \geq 2 \). If \( a \equiv b \pmod{m} \) and \( a \equiv c \pmod{n} \) where \( d = \gcd(m, n) \), then \( b \equiv c \pmod{d} \).

12.44. In Exercise 12.36, it was shown for positive integers \( a, b \) and \( c \) that \( \gcd(a, b, c) = \gcd(\gcd(a, b), c) \). Show that there are integers \( x, y, z \) such that \( \gcd(a, b, c) = ax + by + cz \).

12.45. Suppose that the Euclidean Algorithm is being applied to determine \( \gcd(a, b) \) for two positive integers \( a \) and \( b \). If, at some stage of the algorithm, we arrive at a remainder \( r \) that is a prime number, then what conclusion can be made about \( \gcd(a, b) \)?

## 12.5 RELATIVELY PRIME INTEGERS

For two integers \( a \) and \( b \), not both 0, we know that if \( \gcd(a, b) = 1 \), then there exist integers \( s \) and \( t \) such that \( as + bt = 1 \). What may be surprising is that the converse holds in this special case as well.

**Theorem 12.12** Let \( a \) and \( b \) be integers, not both 0. Then \( \gcd(a, b) = 1 \) if and only if there exist integers \( s \) and \( t \) such that \( 1 = as + bt \).

**Proof** If \( \gcd(a, b) = 1 \), then by Theorem 12.7 there exist integers \( s \) and \( t \) such that \( as + bt = 1 \).

We now consider the converse. Let \( a \) and \( b \) be integers, not both 0, for which there exist integers \( s \) and \( t \) such that \( as + bt = 1 \). By Theorem 12.7, \( \gcd(a, b) \) is the smallest positive integer that is a linear combination of \( a \) and \( b \). Since 1 is a linear combination of \( a \) and \( b \), it follows that \( \gcd(a, b) = 1 \). \( \blacksquare \)
Two integers $a$ and $b$, not both 0, are called relatively prime if \( \gcd(a, b) = 1 \). By Theorem 12.12 then, two integers $a$ and $b$ are relatively prime if and only if 1 is a linear combination of $a$ and $b$. This fact is extremely useful, as we are about to see.

If $a$, $b$ and $c$ are integers such that $a \mid bc$, then there is no reason to believe that $a \mid b$ or $a \mid c$. For example, let $a = 4$, $b = 6$ and $c = 2$. Then $4 \mid 6 \cdot 2$ but $4 \nmid 6$ and $4 \nmid 2$.

However, if $a$ and $b$ are relatively prime, then we can draw another conclusion. The following result is often called Euclid's Lemma.

**Theorem to Prove** (Euclid's Lemma) Let $a$, $b$ and $c$ be integers, where $a \neq 0$. If $a \mid bc$ and $\gcd(a, b) = 1$, then $a \mid c$.

**Proof**

If we use a direct proof, then we assume that $a \mid bc$ and $\gcd(a, b) = 1$. In order to show that $a \mid c$, we need to show that $c$ can be expressed as $ar$ for some integer $r$. Because $a \mid bc$, we know that $bc = aq$ for some integer $q$. Also, because $\gcd(a, b) = 1$, there are integers $s$ and $t$ such that $as + bt = 1$. If we were to multiply $as + bt = 1$ by $c$, then we would have $c = acs + bct$. However, $bc = aq$ and we could factor $a$ from $acs + bct$. This is the plan.

Euclid's Lemma is of special interest when the integer $a$ is a prime.

**Corollary 12.14** Let $b$ and $c$ be integers and $p$ a prime. If $p \mid bc$, then either $p \mid b$ or $p \mid c$.

**Proof**

If $p$ divides $b$, then the corollary is proved. Suppose then that $p$ does not divide $b$. Since the only positive integer divisors of $p$ are 1 and $p$, it follows that $\gcd(p, b) = 1$. Thus, by Euclid's Lemma, $p \mid c$ and the proof is complete.

The preceding corollary can be extended to the case when a prime $p$ divides any product of integers.

**Corollary 12.15** Let $a_1, a_2, \ldots, a_n$, where $n \geq 2$, be integers and let $p$ be a prime. If

$$p \mid a_1 a_2 \cdots a_n,$$

then $p \mid a_i$ for some integer $i$ ($1 \leq i \leq n$).
We proceed by induction. For \( n = 2 \), this is simply a restatement of Corollary 12.14. Assume then that if a prime \( p \) divides the product of \( k \) integers \((k \geq 2)\), then \( p \) divides at least one of the integers. Now let \( a_1, a_2, \ldots, a_{k+1} \) be \( k + 1 \) integers, where \( p \mid a_1a_2 \cdots a_{k+1} \). We show that \( p \mid a_i \) for some \( i \) \((1 \leq i \leq k + 1)\). Let \( b = a_1a_2 \cdots a_k \). So \( p \mid ba_{k+1} \). By Corollary 12.14, either \( p \mid b \) or \( p \mid a_{k+1} \). If \( p \mid a_{k+1} \), then the proof is complete. Otherwise, \( p \mid b \), that is, \( p \mid a_1a_2 \cdots a_k \). However, by the induction hypothesis, \( p \mid a_i \) for some \( i \) \((1 \leq i \leq k)\). In any case, \( p \mid a_i \) for some \( i \) \((1 \leq i \leq k + 1)\).

By the Principle of Mathematical Induction, if a prime \( p \) divides the product of any \( n \geq 2 \) integers, then \( p \) divides at least one of the integers.

There is another useful fact concerning relatively prime integers. Once again, we will have occasion to use the result that whenever two integers \( a \) and \( b \) are relatively prime, then 1 is a linear combination of \( a \) and \( b \).

**Theorem 12.16** Let \( a, b, c \in \mathbb{Z} \), where \( a \) and \( b \) are relatively prime nonzero integers. If \( a \mid c \) and \( b \mid c \), then \( ab \mid c \).

**Proof** Since \( a \mid c \) and \( b \mid c \), there exist integers \( x \) and \( y \) such that \( c = ax \) and \( c = by \). Furthermore, since \( a \) and \( b \) are relatively prime, there exist integers \( s \) and \( t \) such that \( 1 = as + bt \). Multiplying by \( c \) and substituting, we obtain

\[
    c = c \cdot 1 = c(ax + bt) = c(as) + c(bt) = (by)(as) + (ax)(bt) = ab(sy + xt).
\]

Since \((sy + xt)\) is an integer, \( ab \mid c \).

By Theorem 12.16 then, if we wish to show that 12, say, divides some integer \( c \), we need only show that 3 \mid c \) and 4 \mid c \) since \( 12 = 3 \cdot 4 \) and 3 and 4 are relatively prime.

**SECTION 12.5 EXERCISES**

12.46. (a) Let \( a, b, c \in \mathbb{Z} \) such that \( a \neq 0 \) and \( a \mid bc \). Show that if \( \gcd(a, b) \neq 1 \), then \( a \) need not divide \( c \).

(b) Let \( a, b, c \in \mathbb{Z} \) such that \( a, b \neq 0, a \mid c, \) and \( b \mid c \). Show that if \( \gcd(a, b) \neq 1 \), then \( ab \) need not divide \( c \).

12.47. Use Corollary 12.14 to prove that \( \sqrt{3} \) is irrational.

12.48. (a) Prove for every pair \( p, q \) of distinct primes that \( \sqrt{pq} \) is irrational.

(b) Prove for every pair \( p, q \) of distinct primes that \( \sqrt{p} + \sqrt{q} \) is irrational.

12.49. Let \( p \) be a prime and let \( n \in \mathbb{Z} \), where \( n \geq 2 \). Prove that \( p^{1/n} \) is irrational.

12.50. Let \( n \in \mathbb{N} \). Prove or disprove each of the following:

(a) \( 2n \) and \( 4n + 3 \) are relatively prime.

(b) \( 2n + 1 \) and \( 3n + 2 \) are relatively prime.

12.51. (a) Prove that every two consecutive odd positive integers are relatively prime.

(b) State and prove a generalization of the result in (a).

12.52. Prove that if \( p \geq 2 \) is an integer with the property that for every pair \( b, c \) of integers \( p \mid bc \) implies that \( p \mid b \) or \( p \mid c \), then \( p \) is prime. (This result is related to Corollary 12.14.)

12.53. Prove that if \( p \) and \( q \) are primes with \( p \geq q \geq 5 \), then \( 24 \mid (p^2 - q^2) \).
Chapter 12 Proofs in Number Theory

12.54. Recall that a triple \((a, b, c)\) of positive integers such that \(a^2 + b^2 = c^2\) is called a Pythagorean triple. A Pythagorean triple \((a, b, c)\) is called primitive if \(\gcd(a, b) = 1\). (In this case, it also happens that \(\gcd(a, c) = \gcd(b, c) = 1\)).

(a) Prove that if \((a, b, c)\) is a Pythagorean triple, then \((an, bn, cn)\) is a Pythagorean triple for every \(n \in \mathbb{N}\).
(b) In Exercise 4.13, it was shown that if \((a, b, c)\) is a Pythagorean triple, then \(3 \mid ab\). Use this fact and Theorem 12.16 to show that \(12 \mid ab\).
(c) Prove that if \((a, b, c)\) is a primitive Pythagorean triple, then \(a\) and \(b\) are of opposite parity.

12.55. Prove the following: Let \(a, b, m, n \in \mathbb{Z}\), where \(m, n \geq 1\). If \(a \equiv b \pmod{m}\) and \(a \equiv b \pmod{n}\), where \(\gcd(m, n) = 1\), then \(a \equiv b \pmod{mn}\).

12.56. Prove the following: Let \(a, b, c, n \in \mathbb{Z}\), where \(n \geq 2\). If \(ac \equiv bc \pmod{n}\) and \(\gcd(c, n) = 1\), then \(a \equiv b \pmod{n}\).

12.57. For two integers \(a\) and \(b\), not both 0, suppose that \(d = \gcd(a, b)\). Then there exist integers \(x\) and \(y\) such that \(d = ax + by\), that is, \(d\) is a linear combination of \(a\) and \(b\). This implies that \(d\) is also a linear combination of \(x\) and \(y\). Find a necessary and sufficient condition that \(d = \gcd(x, y)\).

12.58. Suppose that the Euclidean Algorithm is being applied to determine \(\gcd(a, b)\) for two positive integers \(a\) and \(b\). If, at some stage of the algorithm, we arrive at remainders \(r_i\) and \(r_{i+1}\) for which \(r_{i+1} = r_i - 1\), then what conclusion can be made about \(\gcd(a, b)\)?

12.59. (a) Let \(a\) and \(b\) be integers different from 0 where \(d = \gcd(a, b)\) and let \(c \in \mathbb{Z}\). Prove that if \(a \mid c\) and \(b \mid c\), then \(ab \mid cd\).
(b) Show that Theorem 12.16 follows as a corollary to the result in (a).

12.60. Prove that there are infinitely many positive integers \(n\) such that each of \(n, n + 1\) and \(n + 2\) can be expressed as the sum of the squares of two nonnegative integers. (For example, observe that \(8 = 2^2 + 2^2\), \(9 = 3^2 + 0^2\), \(10 = 3^2 + 1^2\), \(12 = 3^2 + 3^2\), \(13 = 4^2 + 1^2\), and \(14 = 3^2 + 2^2\).)\(\)

12.61. (a) Give an example of integers \(m, n \geq 5\) such that \(x \cap y \neq \emptyset\) for each \(x \in \mathbb{Z}_m\) and \(y \in \mathbb{Z}_n\).
(b) State a conjecture that provides conditions under which integers \(m, n \geq 2\) have the property that \(x \cap y \neq \emptyset\) for each \(x \in \mathbb{Z}_m\) and \(y \in \mathbb{Z}_n\).

12.6 THE FUNDAMENTAL THEOREM OF ARITHMETIC

It is a basic divisibility fact that every integer can be expressed as a product of primes. This fact is made precise in a famous theorem in number theory. Its proof serves as one of the most interesting uses of the Strong Principle of Mathematical Induction.

Theorem 12.17 (Fundamental Theorem of Arithmetic) Every integer \(n \geq 2\) is either prime or can be expressed as a product of primes, that is,

\[ n = p_1 p_2 \cdots p_m, \]

where \(p_1, p_2, \ldots, p_m\) are primes. Furthermore, this factorization is unique except possibly for the order in which the factors occur.

Proof To show the existence of such a factorization, we employ the Strong Principle of Mathematical Induction. Since 2 is a prime, the statement is certainly true for \(n = 2\).

For an integer \(k \geq 2\), assume that every integer \(i\), with \(2 \leq i \leq k\), is either prime or can be expressed as a product of primes. We show that \(k + 1\) is either prime or can
be expressed as a product of primes. Of course, if \( k + 1 \) is prime, then there is nothing further to prove. We may assume, then, that \( k + 1 \) is composite. By Lemma 12.1, there exist integers \( a \) and \( b \) such that \( k + 1 = ab \), where \( 2 \leq a \leq k \) and \( 2 \leq b \leq k \). Therefore, by the induction hypothesis, each of \( a \) and \( b \) is prime or can be expressed as a product of primes. In any case, \( k + 1 = ab \) is a product of primes.

By the Strong Principle of Mathematical Induction, every integer \( n \geq 2 \) is either prime or can be expressed as a product of primes.

It remains to show that such a factorization is unique. To do this, we proceed by contradiction. Assume, to the contrary, that there is an integer \( n \geq 2 \) that can be expressed as a product of primes in two different ways, say

\[
n = p_1p_2 \cdots p_s = q_1q_2 \cdots q_t,
\]

where in each factorization, the primes are arranged in nondecreasing order, that is, \( p_1 \leq p_2 \leq \cdots \leq p_s \) and \( q_1 \leq q_2 \leq \cdots \leq q_t \). Since the factorizations are different, there must be a smallest positive integer \( r \) such that \( p_r \neq q_r \). In other words, if \( r \geq 2 \), then \( p_i = q_i \) for every \( i \) with \( 1 \leq i \leq r - 1 \). After canceling, we have

\[
p_rp_{r+1} \cdots p_s = q_rq_{r+1} \cdots q_t. \tag{12.6}
\]

Consider the integer \( p_r \). Either \( s = r \) and the left side of (12.6) is exactly \( p_r \) or \( s > r \) and \( p_{r+1}p_{r+2} \cdots p_s \) is an integer that is the product of \( s - r \) primes. In either case, \( p_r \mid q_rq_{r+1} \cdots q_t \). Therefore, by Corollary 12.15, \( p_r \mid q_j \) for some \( j \) with \( r \leq j \leq t \). Because \( q_j \) is prime, \( p_r = q_j \). Since \( q_r \leq q_j \), it follows that \( q_r \leq p_r \). By considering the integer \( q_r \) (instead of \( p_r \)), we can show that \( p_r \leq q_r \). Therefore, \( p_r = q_r \). But this contradicts the fact that \( p_r \neq q_r \). Hence, as claimed, every integer \( n \geq 2 \) has a unique factorization.

An immediate consequence of Theorem 12.17 is stated next.

**Corollary 12.18**

Every integer exceeding 1 has a prime factor.

In fact, we can say a bit more.

**Lemma 12.19**

If \( n \) is a composite number, then \( n \) has a prime factor \( p \) such that \( p \leq \sqrt{n} \).

**Proof**

Since \( n \) is composite, we know that \( n = ab \), where \( 1 < a < n \) and \( 1 < b < n \). Assume, without loss of generality, that \( a \leq b \). Then \( a^2 \leq ab = n \) and hence, \( a \leq \sqrt{n} \). Since \( a > 1 \), we know that \( a \) has a prime factor, say \( p \). Because \( a \) is a factor of \( n \), it follows that \( p \) is a factor of \( n \) as well and \( p \leq a \leq \sqrt{n} \).

If an integer \( n \geq 2 \) is expressed as a product \( q_1q_2 \cdots q_m \) of primes, then the primes \( q_1, q_2, \ldots, q_m \) need not be distinct. Consequently, we can group equal prime factors and express \( n \) in the form

\[
n = p_1^{a_1}p_2^{a_2} \cdots p_k^{a_k},
\]

where \( p_1, p_2, \ldots, p_k \) are primes such that \( p_1 < p_2 < \cdots < p_k \) and each exponent \( a_i \) is a positive integer. We call this the **canonical factorization** of \( n \). From the Fundamental Theorem of Arithmetic, every integer \( n \geq 2 \) has a unique canonical factorization.
For example, the canonical factorizations of 12, 210 and 1000 are $12 = 2^2 \cdot 3$, $210 = 2 \cdot 3 \cdot 5 \cdot 7$, and $1000 = 2^3 \cdot 5^3$. Of course, it is relatively easy to determine whether a small positive integer is prime or composite and, if it is composite, to express it as a product of primes. We mention some tests for divisibility by certain integers. These may already be known to you.

1. **Divisibility by 2, 4 and other powers of 2:**
   An integer $n$ is divisible by 2 if and only if $n$ is even (or the last digit of $n$ is even). In fact, $n$ is divisible by 4 if and only if the two-digit number consisting of the last two digits of $n$ is divisible by 4, the integer $n$ is divisible by 8 if and only if the three-digit number consisting of the last three digits of $n$ is divisible by 8, and so on. Therefore, the number 14220 is divisible by 4 since 20 is divisible by 4 but it is not divisible by 8 since 220 is not divisible by 8.

2. **Divisibility by 3 and 9:**
   An integer is divisible by 3 if and only if the sum of its digits is divisible by 3. Indeed, an integer is divisible by 9 if and only if the sum of its digits is divisible by 9. This procedure stops with 9, however; that is, it doesn’t extend to 27. For example, the sum of the digits of 27 itself is not divisible by 27 but certainly 27 is divisible by 27. The sum of the digits of the integer 4278 is 21, which is divisible by 3 but not by 9. Consequently, 4278 is divisible by 3 but not by 9. Clearly, 4278 is divisible by 2, but it is not divisible by 4 since 78 is not divisible by 4. Thus, 4278 is divisible by 6 by Theorem 12.16.

3. **Divisibility by 5:**
   An integer is divisible by 5 if and only if it ends in 5 or 0; that is, an integer is divisible by 5 if and only if its last digit is divisible by 5.

4. **Divisibility by 11:**
   Start with the first digit of $n$ and sum alternate digits (every other digit). Suppose that the resulting number is $a$. Then sum the remaining digits, obtaining $b$. Then $n$ is divisible by 11 if and only if $a - b$ is divisible by 11. For example, consider the number 71929. Observe that $a = 7 + 9 + 9 = 25$, while $b = 1 + 2 = 3$. Since $25 - 3 = 22$ is divisible by 11, the number 71929 is divisible by 11. In fact, $71929 = 11 \cdot 6539$. However, since $(6 + 3) - (5 + 9) = -5$ is not divisible by 11, the integer 6539 is not divisible by 11; that is, 71929 is not divisible by $11^2 = 121$.

Although there are tests for divisibility by other primes such as 7 (see Exercise 12.66) and 13, none of these are sufficiently practical to merit inclusion here. If we apply the tests listed above to the number $n = 471240$, then we find that $n$ is divisible by 5, 8 (but not 16), 9 and 11. Indeed, $n = 5 \cdot 8 \cdot 9 \cdot 11 \cdot 119 = 5 \cdot 8 \cdot 9 \cdot 11 \cdot 7 \cdot 17 = 2^3 \cdot 3^2 \cdot 5 \cdot 7 \cdot 11 \cdot 17$.

We are now in a position to describe an infinite class of irrational numbers.

**Theorem 12.20**

Let $n$ be a positive integer. Then $\sqrt{n}$ is a rational number if and only if $\sqrt{n}$ is an integer.

**Proof**

Certainly, if $\sqrt{n}$ is an integer, then $\sqrt{n}$ is rational. Hence, we need only verify the converse. Assume, to the contrary, that there exists some positive integer $n$ such that $\sqrt{n}$ is a rational number but $\sqrt{n}$ is not an integer. Hence, $\sqrt{n} = a/b$ for some positive
integers \( a \) and \( b \). Furthermore, we may assume that \( a \) and \( b \) have no common factors, that is, \( \gcd(a, b) = 1 \). Since \( a/b \) is not an integer, \( b \geq 2 \). Therefore, \( n = a^2/b^2 \) and so \( a^2 = nb^2 \). By Corollary 12.18, \( b \) has a prime factor \( p \). Thus, \( p \mid nb^2 \) and so \( p \mid a^2 \). By Corollary 12.14, \( p \mid a \). But then \( p \mid a \) and \( p \mid b \), which contradicts our assumption that \( \gcd(a, b) = 1 \).

A consequence of this theorem is the following.

**Corollary 12.21**

If \( p \) is a prime, then \( \sqrt{p} \) is irrational.

**Proof**

Assume, to the contrary, that there exists some prime \( p \) for which \( \sqrt{p} \) is rational. By Theorem 12.20, \( \sqrt{p} = n \) for some integer \( n \geq 2 \). Then \( p = n^2 \). Because \( n^2 \) is composite, this is a contradiction.

Corollary 12.21 tells us that both \( \sqrt{2} \) and \( \sqrt{3} \) are irrational, which we have seen often. Although our remarks imply that there are infinitely many primes, we have yet to prove this. We do this now. Since our goal is to prove that the number of primes is not finite, a proof by contradiction is the expected technique.

**Theorem 12.22**

The number of primes is infinite.

**Proof**

Assume, to the contrary, that the number of primes is finite. Let \( P = \{p_1, p_2, \ldots, p_n\} \) be the set of all primes. Let \( r = p_1p_2 \cdots p_n \) and consider \( m = r + 1 \). Clearly, \( m \geq 2 \). Since \( 1 = 1 \cdot m + (-1)r \) is a linear combination of \( m \) and \( r \), it follows by Theorem 12.12 that \( m \) and \( r \) are relatively prime. Since every prime divides \( r \), no prime divides \( m \). This contradicts Corollary 12.18.

Two primes \( p \) and \( q \), where \( p < q \), are called twin primes if \( q = p + 2 \). Necessarily, twin primes are odd. For example, 5, 7 and 11, 13 are twin primes. Although we have just verified that there are infinitely many primes, the number of twin primes is not known.

**Conjecture 12.23**

There are infinitely many twin primes.

If Conjecture 12.23 is true, then there are infinitely many distinct pairs \( p, q \) of primes with \( q = p + 2 \). In particular, if one considers the sequence 3—2, 5—3, 7—5, 11—7, 13—11, 17—13, \ldots \) of consecutive prime gaps (that is, 1, 2, 2, 4, 2, 4, \ldots), then Conjecture 12.23 states that this sequence has an infinite number of 2s. In 2013, Yitang Zhang proved that this sequence contains an infinite number of terms less than 70,000,000 (a fact not known before). Since 2016, the number 70,000,000 has been reduced to 4680.

**SECTION 12.6 EXERCISES**

12.62. Find the smallest prime factor of each integer below:

(a) 539 \hspace{1cm} (b) 1575 \hspace{1cm} (c) 529 \hspace{1cm} (d) 1601.

12.63. Find the canonical factorization of each of the following integers:

(a) 4725 \hspace{1cm} (b) 9702 \hspace{1cm} (c) 180625.
322 Chapter 12 Proofs in Number Theory

12.64. Prove each of the following:
   (a) Every prime of the form $3n + 1$ is also of the form $6k + 1$.
   (b) If $n$ is a positive integer of the form $3k + 2$, then $n$ has a prime factor of this form as well.

12.65. (a) Express each of the integers 4278 and 71929 as a product of primes.
   (b) What is $\gcd(4278, 71929)$?

12.66. Consider the periodic sequence $1, 3, 2, -1, -3, 2, -1, -3, -2, -3$ which we write in reverse order:
   \[
   \ldots, -2, -3, -1, 2, 3, 1, -2, -3, -1, 2, 3, 1.
   \]
   Next, consider the 8-digit positive integer $n = a_7a_6a_5a_4a_3a_2a_1a_0$ where each $a_i$ is a digit. It turns out that $7 \mid n$ if and only if
   \[
   3 \cdot a_7 + 1 \cdot a_6 + (-2) \cdot a_5 + (-3) \cdot a_4 + (-1) \cdot a_3 + 2 \cdot a_2 + 3 \cdot a_1 + 1 \cdot a_0
   \]
   is a multiple of 7. Use this to determine which of the following are multiples of 7:
   (a) 56 (b) 821,317 (c) 31,142,524.

12.67. In the proof of Theorem 12.22, it was proved that there are infinitely many primes by assuming that there were finitely many primes, say $p_1, p_2, \ldots, p_n$, where $p_1 < p_2 < \cdots < p_n$. The number $m = p_1p_2\cdots p_n + 1$ was then considered to obtain a contradiction. Show that an alternative proof of Theorem 12.22 can be obtained by considering $p_n! + 1$ instead of $m$.

12.68. Determine a necessary and sufficient condition that $p_1^{a_1}p_2^{a_2}\cdots p_k^{a_k}$ is the canonical factorization of the square of some integer $n \geq 2$.

12.69. For two integers $m, n \geq 2$, let $p_1, p_2, \ldots, p_r$ be those distinct primes such that each $p_i$ ($1 \leq i \leq r$) divides at least one of $m$ and $n$. Then $m$ and $n$ can be expressed as $m = p_1^{b_1}p_2^{b_2}\cdots p_r^{b_r}$ and $n = p_1^{b_1}p_2^{b_2}\cdots p_r^{b_r}$ where the integers $a_i$ and $b_i$ ($1 \leq i \leq r$) are nonnegative. Let $c_i = \min(a_i, b_i)$ for $1 \leq i \leq r$. Prove that
   \[
   \gcd(m, n) = p_1^{c_1}p_2^{c_2}\cdots p_r^{c_r}.
   \]

12.7 CONCEPTS INVOLVING SUMS OF DIVISORS

We close this chapter by discussing some curious concepts involving sums of divisors of an integer. For an integer $n \geq 2$, a positive integer $a$ is called a proper divisor of $n$ if $a \mid n$ and $a < n$. Thus, the proper divisors of 6 are 1, 2 and 3, while the proper divisors of 28 are 1, 2, 4, 7 and 14. Note also that

\[
1 + 2 + 3 = 6 \quad \text{and} \quad 1 + 2 + 4 + 7 + 14 = 28.
\]

A positive integer $n \geq 2$ is called perfect if the sum of its proper divisors is $n$. Hence, 6 and 28 are perfect integers – indeed, they are the two smallest perfect integers. The third smallest perfect integer is 496. The largest prime divisors of 6, 28 and 496 are 3, 7 and 31, respectively. Summing the integers from 1 to each of these primes yields possibly unexpected results:

\[
1 + 2 + 3 = 6
\]
\[
1 + 2 + 3 + 4 + 5 + 6 + 7 = 28
\]
\[
1 + 2 + \cdots + 31 = 496.
\]
The integers 6, 28 and 496 can also be expressed as
\[ 6 = 2^1(2^2 - 1), \quad 28 = 2^2(2^3 - 1) \quad \text{and} \quad 496 = 2^4(2^5 - 1). \]

In fact, Euclid, the famous geometer who lived more than 2000 years ago, showed that whenever \(2^p - 1\) is a prime, then \(2^{p-1}(2^p - 1)\) is a perfect integer. During the 18th century the brilliant Swiss mathematician Leonhard Euler proved that every even perfect integer is of the form \(2^{p-1}(2^p - 1)\) where \(2^p - 1\) is a prime. Prime numbers of the form \(2^p - 1\) are referred to as Mersenne primes. As of January 2016, 49 Mersenne primes were known and therefore 49 even perfect integers were known.

Much mystery surrounds perfect numbers. Are there any odd perfect numbers? No one knows. Are there infinitely many even perfect numbers? No one knows that either.

Let’s consider the first few primes — the first seven to be exact: 2, 3, 5, 7, 11, 13, 17. The 1st, 2nd, 4th and 7th primes are 2, 3, 7 and 17 and the remaining primes (the 3rd, 5th and 6th) are 5, 11 and 13. If we add the integers 1, 2, 4 and 7, we get the same result as when we add 3, 5 and 6, namely, \(1 + 2 + 4 + 7 = 3 + 5 + 6 = 14\). That is, it is possible to partition the first seven positive integers into two sets such that the sums of the integers in each set are the same. While this fact may not appear to be anything special, it is also a fact that summing the primes that correspond to these two sets of integers also gives the same result:

\[ 2 + 3 + 7 + 17 = 5 + 11 + 13 = 29. \]

While the sums of these primes are equal, it is impossible for the products of these primes, namely \(2 \cdot 3 \cdot 7 \cdot 17\) and \(5 \cdot 11 \cdot 13\), to be equal. This is a consequence, of course, of the Fundamental Theorem of Arithmetic. On the other hand, these products are surprisingly close since

\[ 2 \cdot 3 \cdot 7 \cdot 17 = 714 \quad \text{and} \quad 5 \cdot 11 \cdot 13 = 715. \]

The serious baseball fan will recognize these numbers. For years, the number 714 stood as the record for home runs in a career. This record was held by Babe Ruth. However, this record was broken in 1974 when Hank Aaron hit his 715th home run.

Two consecutive integers \(n, \ n+1\) are called Ruth-Aaron pairs of integers if the sums of their prime divisors are equal. Thus, 714 and 715 is a Ruth-Aaron pair, as are 5 and 6. Although such pairs of integers may appear to be rare, the famous Hungarian mathematician Paul Erdős proved that there are, in fact, infinitely many Ruth-Aaron pairs of integers.

**SECTION 12.7 EXERCISES**

12.70. Let \(k\) be a positive integer.

(a) Prove that if \(2^k - 1\) is prime, then \(k\) is prime.

(b) Prove that if \(2^k - 1\) is prime, then \(n = 2^{k-1}(2^k - 1)\) is perfect.
12.71. Recall, for a real number \( r \), that the floor \( \lfloor r \rfloor \) of \( r \) is the greatest integer less than or equal to \( r \). The greatest number of distinct positive integers whose sum is 5 is 2 (5 = 1 + 4 = 2 + 3), while the greatest number of distinct positive integers whose sum is 8 is 3 (8 = 1 + 2 + 5 = 1 + 3 + 4). Prove that the maximum number of distinct positive integers whose sum is the positive integer \( n \) is \( \lfloor (\sqrt{1 + 8n} - 1) / 2 \rfloor \).

Chapter 12 Supplemental Exercises

12.72. Evaluate the proposed solution of the following problem.

Prove or disprove the following statement:

There do not exist three integers \( n, n + 2 \) and \( n + 4 \), all of which are primes.

Solution

This statement is true.

Proof

Assume, to the contrary, that there exist three integers \( n, n + 2 \) and \( n + 4 \), all of which are primes. We can write \( n \) as \( 3q, 3q + 1 \) or \( 3q + 2 \), where \( q \in \mathbb{Z} \). We consider these three cases.

Case 1. \( n = 3q \). Then \( 3 \mid n \) and so \( n \) is not prime. This is a contradiction.

Case 2. \( n = 3q + 1 \). Then \( n + 2 = 3q + 3 = 3(q + 1) \). Since \( q + 1 \) is an integer, \( 3 \mid (n + 2) \) and so \( n + 2 \) is not prime. Again, we have a contradiction.

Case 3. \( n = 3q + 2 \). Hence, we have \( n + 4 = 3q + 6 = 3(q + 2) \). Since \( q + 2 \) is an integer, \( 3 \mid (n + 4) \) and so \( n + 4 \) is not prime. This produces a contradiction.

12.73. An integer \( a \geq 2 \) is defined to be lucky if \( f(n) = n^2 - n + a \) is prime for every integer \( n \) with \( 1 \leq n \leq a - 1 \). It is known that (1) 41 is lucky and (2) only nine other integers \( a \geq 2 \) are lucky.

(a) Prove that if \( a \) is a lucky integer, then \( a \) is prime.

(b) Give an example of three other lucky integers.

(c) If \( a \) is a lucky integer, what can be said about \( f(a) \)?

12.74. Prove that \( \log_2 3 \) is irrational.

12.75. State and prove a more general result than that given in Exercise 12.74.

12.76. Given below is an incomplete result with an incomplete proof. This result is intended to determine all twin primes (primes of the form \( p \) and \( q = p + 2 \)) such that \( pq - 2 \) is also prime.

Result

Let \( p \) and \( q = p + 2 \) be two primes. Then \( pq - 2 \) is prime if and only if (complete this sentence).

Proof

Let \( p \) and \( q = p + 2 \) be two primes such that \( pq - 2 \) is also prime. Since \( p \) and \( p + 2 \) are both primes, it follows that \( p \) is odd. By the Division Algorithm, we can write \( p = 3k + r \), where \( k \in \mathbb{Z} \) and \( 0 \leq r \leq 2 \). Since \( p \) is an odd prime, \( k \geq 1 \). We consider three cases for \( p \), depending on the value of \( r \).

Case 1. \( p = 3k \). Therefore, \( p = \), \( q = \) and \( pq - 2 = \).
Case 2. \( p = 3k + 1 \). Hence, \( q = 3k + 3 \). Since \( k \geq 1 \), it follows that \( q = 3(k + 1) \). Therefore,

Case 3. \( p = 3k + 2 \). Then \( q = 3k + 4 \). Thus,

12.77. Exercise 12.76 should suggest another exercise to you. State a result related to Exercise 12.76 and give a proof of this result.

12.78. Assume that each positive rational number is expressed as \( m/n \), where \( m, n \in \mathbb{N} \) and \( m \) and \( n \) are relatively prime. A function \( f: \mathbb{Q}^+ \to \mathbb{N} \) is defined by \( f(m/n) = 2^m3^n \).

(a) Prove that \( f \) is one-to-one.

(b) According to the Schröder–Bernstein Theorem (Theorem 11.20), what information about \( \mathbb{Q}^+ \) does the result in (a) provide?

12.79. We have seen in Section 12.7 that there is a partition of the set of the first seven primes into two subsets such that the sums of the elements in these two subsets are equal. Show that there is no such partition of the set of the first eight primes but there is such a partition of the set of the first nine primes.

12.80. (a) Show that \( 5039 = 5040 - 1 \) is prime, while \( 5041 = 5040 + 1 \) is not prime.

(b) Show that, except for 5039, there is no prime between \( 5033 = 5040 - 7 \) and \( 5047 = 5040 + 7 \).

12.81. Let \( a_0, a_1, a_2, \ldots \) be a sequence of positive integers for which

1. \( a_0 = 1 \),
2. \( a_{2n+1} = a_n \) for \( n \geq 0 \) and
3. \( a_{2n+2} = a_n + a_{n+1} \) for \( n \geq 0 \).

Prove that \( a_n \) and \( a_{n+1} \) are relatively prime for every nonnegative integer \( n \).

12.82. The decimal expansion of every positive integer \( n \) can be expressed as

\[
 n = a_k a_{k-1} \cdots a_2 a_1 a_0, \quad \text{that is,} \quad n = a_k \cdot 10^k + a_{k-1} \cdot 10^{k-1} + \cdots + a_2 \cdot 10^2 + a_1 \cdot 10 + a_0.
\]

It was mentioned in Section 12.6 that \( 9 \mid n \) if and only if \( 9 \mid (a_k + a_{k-1} + \cdots + a_2 + a_1 + a_0) \). For example, for the integer \( n = 32,751 \), \( 9 \mid (3 + 2 + 7 + 5 + 1) \) and so \( 9 \mid 32,751 \). Verify this by using the fact that \( 10 = 9 + 1 \) and for a positive integer \( r \) that \( 10^r = (9 + 1)^r = 9s + 1 \) for some integer \( s \).

12.83. Let \( A \) be the set of 2-element subsets of \( \mathbb{N} \) and \( B \) the set of 3-element subsets of \( \mathbb{N} \). Let \( f: A \to B \) and \( g: B \to A \) be functions defined by

\[
 f([i, j]) = [i, j, i + j] \quad \text{and} \quad g([i, j, k]) = \{2^i, 3^j, 5^k\},
\]

where \( i < j < k \). With the aid of the functions \( f \) and \( g \) and possibly the Schröder–Bernstein Theorem (Theorem 11.20 in Chapter 11), which of the following are we able to conclude?

(a) \( |A| \leq |B| \)

(b) \( |B| \leq |A| \)

(c) \( |A| = |B| \)

(d) Nothing.

12.84. Let \( p_1, p_2, p_3, \ldots \) be the primes, where \( 2 = p_1 < p_2 < p_3 < \cdots \). Let \( A \) be a denumerable set, where \( A = \{a_1, a_2, a_3, \ldots\} \). For any integer \( n \geq 2 \), let \( A^n \) denote the Cartesian product of \( n \) copies of \( A \), that is, \( A^n \) is the set of ordered \( n \)-tuples of elements of \( A \). Define a function \( f: A^n \to \mathbb{N} \) by \( f((a_{i_1}, a_{i_2}, \ldots, a_{i_n})) = p_{i_1} p_{i_2} \cdots p_{i_n} \).

(a) Prove that \( f \) is injective.
326 Chapter 12 Proofs in Number Theory

(b) Use (a) to show that $A^n$ and $A$ are numerically equivalent.
(c) For every two denumerable sets $A$ and $B$ and every two integers $n, m \geq 2$, show that $A^n$ and $B^m$ are numerically equivalent.

12.85. Let $p_1, p_2, \ldots, p_{n+1}$ denote the first $n + 1$ primes. Suppose that $\{U, V\}$ is a partition of the set $S = \{p_1, p_2, \ldots, p_n\}$, where $U = \{q_1, q_2, \ldots, q_s\}$ and $V = \{r_1, r_2, \ldots, r_t\}$. Prove that if $M = q_1q_2 \cdots q_s + r_1r_2 \cdots r_t < p_{n+1}$, then $M$ is a prime.

12.86. We have seen on several occasions (Exercise 12.4, for example) that $3 \mid (n^3 - n)$ for every integer $n$ and so $3 \mid (n^3 - n)$ for every positive integer $n$.
(a) Prove, in fact, that $6 \mid (n^3 - n)$ for every positive integer $n$.
(b) Prove that if $a$ and $b$ are integers such that $6 \mid (a - b)$, then $6 \mid (an^3 - bn)$ for every positive integer $n$.

12.87. We have seen that $\sqrt{p}$ is irrational for every prime $p$ and for every two distinct primes $p$ and $q$ that $\sqrt{p} + \sqrt{q}$ is irrational (Exercise 12.48(b)). Prove, for every three distinct primes $p, q$ and $r$, that the number $\sqrt{p} + \sqrt{q} + \sqrt{r}$ is irrational.

12.88. Determine all integer solutions to the system of congruences

\[ x \equiv 3 \pmod{5} \quad x \equiv 4 \pmod{7} \]
13

Proofs in Combinatorics

Discrete mathematics is a branch of mathematics that has grown both in importance and popularity in recent decades. This area deals more with integers than with real numbers and involves subsets of a given set and arrangements of their elements. That part of discrete mathematics concerning subsets and arrangements belongs to the area called combinatorics. The primary goal of this chapter is to introduce some of the fundamental concepts in combinatorics, to describe some proofs that occur in this area and to see examples of how this subject can be used to solve a variety of problems.

13.1 THE MULTIPLICATION AND ADDITION PRINCIPLES

Many of the problems that occur in combinatorics can be analyzed and solved with the aid of several principles, each of which is used to enumerate the number of possible ways a given event can occur, subject to certain prescribed conditions. The principle that occurs most often is the Multiplication Principle. Here, there is a certain procedure to perform, which is accomplished by performing a number of tasks, one after another.

There are situations when a certain procedure consists of two tasks, where the second task is performed only after the first task has been performed. We say that the procedure itself is performed when the two tasks are performed. If we know the number of ways in which each of the two tasks can be performed, then the multiplication principle tells us the number of ways that the procedure can be performed.

The Multiplication Principle

A procedure consists of two tasks. To perform this procedure, one performs the first task followed by performing the second task. If there are \( n_1 \) ways to perform the first task and \( n_2 \) ways to perform the second task after the first task has been performed, then there are \( n_1n_2 \) ways to perform the procedure.

Let’s look at an example of this.

Example 13.1

A take-home exam for a course consists of selecting and solving one of four given problems (numbered 1, 2, 3, 4) and selecting and writing an essay on one of three given topics (denoted by \( A, B, C \)). How many different such exams are possible for a student in the course?
Chapter 13  Proofs in Combinatorics

Solution  Let \( T_1 \) denote the task of selecting one of the four given problems to solve and \( T_2 \) the task of selecting one of the three given topics on which to write an essay. By the Multiplication Principle, the total number of different exams is \( 4 \cdot 3 = 12 \).

The answer to the question posed in Example 13.1 can also be given with the aid of the diagram shown in Figure 13.1, called a tree diagram. We start at the top of the diagram (called the root in this case) and proceed down along one of four possible paths in the diagram according to which of the four possible problems we have selected to solve. Once a decision is made as to which problem will be selected, there are then three possible paths from there we could take, corresponding to the topics on which we choose to write an essay. A completed path terminates at one of 12 possible locations.

![Figure 13.1  A tree diagram for Example 13.1](image)

Despite the fact that the Multiplication Principle described above is for procedures consisting of two tasks, this principle need not be restricted to two tasks. This suggests the following more general principle.

The (General) Multiplication Principle

Performing a certain procedure consists of performing a sequence of \( m \geq 2 \) tasks \( T_1, T_2, \ldots, T_m \). If there are \( n_i \) ways of performing \( T_i \) (\( 1 \leq i \leq m \)) after any preceding tasks have been performed, then the total number of ways of performing the procedure is \( n_1 n_2 \cdots n_m \).

Proof  We proceed by induction. By the Multiplication Principle stated earlier, the result holds for \( n = 2 \). Assume that this principle is true for an integer \( k \geq 2 \) and let \( P \) be the procedure that consists of performing \( k + 1 \) tasks \( T_1, T_2, \ldots, T_{k+1} \) in succession, where the number of ways to perform \( T_i \) is \( n_i \) for \( 1 \leq i \leq k + 1 \). Let \( P' \) be the procedure that results from performing the first \( k \) tasks \( T_1, T_2, \ldots, T_k \) in succession. Thus, \( P' \) itself can be considered as a task and \( P \) then as the procedure produced by performing \( T_{k+1} \) after the task \( P' \) is performed. By the induction hypothesis, the number of ways to perform \( P' \) is \( n_1 n_2 \cdots n_k \) and so the number of ways to perform \( P \) is \( (n_1 n_2 \cdots n_k)n_{k+1} \). The (General) Multiplication Principle then follows by the Principle of Mathematical Induction.

When we refer to the Multiplication Principle, we are then referring to the (General) Multiplication Principle, whether \( m = 2 \) or \( m > 2 \).

Let’s now look at two examples that address questions which can be answered with the aid of the Multiplication Principle. A finite sequence is often referred to as a string and the number of terms in a string is its length. A bit (or binary digit) is a 0 or 1 and a
13.1 The Multiplication and Addition Principles

A *bit string* is a string in which each term is a bit. An *n-bit string* is a bit string of length $n$. Therefore, the strings 10110, 00100 and 01101 are all 5-bit strings.

**Example 13.2**

(a) How many $n$-bit strings are there?

(b) How many 10-bit strings are there?

(c) How many 8-bit strings begin and end with 0?

**Solution**

(a) Since there are two possible choices for each term in an $n$-bit string, it follows by the Multiplication Principle that the number of $n$-bit strings is $2^n$.

(b) $2^{10} = 1024$ by (a).

(c) Since there are two possible choices for each of the six interior terms in such an 8-bit string, there are $2^6 = 64$ possible 8-bit strings that begin and end with 0.

**Example 13.3**

In order for someone to access a certain website, we need to know both the person’s username and password. Suppose that we were able to learn that the username of a person is a 5-digit number where the 1st, 3rd and 5th digits are odd (namely, 1, 3, 5, 7 or 9) and the remaining two digits are nonzero even digits (namely 2, 4, 6 or 8). Furthermore, we found that the person’s password is a 5-letter word, where the 1st, 3rd and 5th letters are vowels (where y as well as a, e, i, o, u are vowels in this case), while the remaining two letters are consonants (non-vowels). How many times would we need to attempt to log in to the website until we are guaranteed entrance into the website?

**Solution**

Since there are five possible digits for the 1st, 3rd and 5th digits of the number and four possible choices for the 2nd and 4th digits, the number of possible usernames by the Multiplication Principle is $5 \cdot 4 \cdot 5 \cdot 4 \cdot 5 = 2000$. Since $6 \cdot 20 \cdot 6 \cdot 20 \cdot 6 = 6^3 \cdot 20^2 = 86,400$, there are 86,400 possible passwords by the Multiplication Principle. Once again, by the Multiplication Principle, the maximum number of attempts needed to log in to the website to guarantee access to it is $(2000)(86,400) = 172,800,000$.

There is another way to look at the Multiplication Principle – in terms of sets. Once again, suppose that performing a certain procedure $P$ consists of performing $m \geq 2$ tasks $T_1, T_2, \ldots, T_m$ in succession. Furthermore, suppose that there are $n_i$ ways to perform $T_i$ for each $i$ with $1 \leq i \leq m$. Let $A_i$ denote the set of all possible ways of performing the task $T_i$; so $|A_i| = n_i$. Then the Cartesian product $A_1 \times A_2 \times \cdots \times A_m$ is the set of all possible ways to perform $P$. In Section 1.6, it was mentioned that $|A \times B| = |A| \cdot |B|$ for every two finite sets $A$ and $B$. From this, it follows for $m \geq 2$ finite sets $A_1, A_2, \ldots, A_m$ with $|A_i| = n_i$ for $1 \leq i \leq m$ that

$$|A_1 \times A_2 \times \cdots \times A_m| = |A_1| \cdot |A_2| \cdot \cdots \cdot |A_m| = n_1 n_2 \cdots n_m.$$  \hspace{1cm} (13.1)

(See Exercise 13.3.)

We now turn to a second principle that is encountered often in combinatorics. There are occasions when performing a certain procedure consists of performing one of two tasks that cannot be performed at the same time. Here, we say that the procedure is performed if either task is performed. If we know the number of ways in which each of
the two tasks can be performed, then the Addition Principle tells us of the number of ways that such a procedure can be performed.

**The Addition Principle**

A procedure consists of two tasks that cannot be performed simultaneously. To perform this procedure, either of the two tasks is performed. If one of the tasks can be performed in \( n_1 \) ways and the other can be performed in \( n_2 \) ways, then the number of ways of performing this procedure is \( n_1 + n_2 \).

Answering the question in the example below can be done with the aid of the Addition Principle.

**Example 13.4**

Let \( S = \{1, 2, \ldots, 9\} \). Let \( T_1 \) be the task of selecting an even number from \( S \), let \( T_2 \) be the task of selecting an odd number from \( S \) and let \( T_3 \) be the task of selecting an odd prime from \( S \).

(a) Let \( P_1 \) be the procedure consisting of performing either of the tasks \( T_1 \) and \( T_2 \). In how many ways can \( P_1 \) be performed?

(b) Let \( P_2 \) be the procedure consisting of performing either of the tasks \( T_1 \) and \( T_3 \). In how many ways can \( P_2 \) be performed?

**Solution**

(a) Since there are four ways of performing the task \( T_1 \) and five ways of performing the task \( T_2 \), it follows by the Addition Principle that there are \( 4 + 5 = 9 \) ways to perform the procedure \( P_1 \).

(b) Once again, there are four ways of performing the task \( T_1 \). Since the set \( S \) contains three odd primes (namely 3, 5 and 7), there are three ways to perform the task \( T_3 \). By the Addition Principle, there are \( 4 + 3 = 7 \) ways to perform the procedure \( P_2 \).

**Analysis**

It may seem that there is a third possible question that could have been asked concerning Example 13.4. That is, if we were to let \( P_3 \) be the procedure consisting of performing either of the tasks \( T_2 \) and \( T_3 \), then in how many ways can \( P_3 \) be performed? While this question is appropriate, it cannot be answered with the aid of the Addition Principle as selecting any of the integers 3, 5 or 7 from \( S \) performs \( T_2 \) and \( T_3 \) simultaneously. In addition, if a new task \( T_4 \) is defined as selecting a prime from \( S \) and \( P_4 \) is the procedure consisting of performing either of the tasks \( T_1 \) and \( T_4 \), then the number of ways that \( P_4 \) can be performed also cannot be determined with the aid of the Addition Principle as selecting the integer 2 from \( S \) shows that the tasks \( T_1 \) and \( T_4 \) can be performed simultaneously. In Section 13.2, we will see another principle that allows us not only to determine the number of ways that \( P_3 \) and \( P_4 \) can be performed but allows us to answer an even wider range of questions.

As with the Multiplication Principle, there is a more general version of the Addition Principle.

**The (General) Addition Principle**

Suppose, for an integer \( m \geq 2 \), that a procedure consists of performing one of \( m \) tasks \( T_1, T_2, \ldots, T_m \), where it is impossible to perform any two of these tasks at the same time and where the number of ways to perform \( T_i \) (\( 1 \leq i \leq m \)) is \( n_i \). Then the total number of ways to perform the procedure is \( n_1 + n_2 + \cdots + n_m \).
Section 13.1 Exercises

Proof Here too, we proceed by induction. The case where \( n = 2 \) is precisely the Addition Principle described above. Assume that this principle is true for \( k \) tasks, where \( k \geq 2 \), and let \( P \) be the procedure that consists of performing one of \( k + 1 \) tasks \( T_1, T_2, \ldots, T_{k+1} \), where it is impossible to perform any two of these tasks at the same time and where the number of ways to perform \( T_i \) is \( n_i \) for \( 1 \leq i \leq k + 1 \). Let \( P' \) be the procedure of performing any one of the \( k \) tasks \( T_1, T_2, \ldots, T_k \). The procedure \( P' \) can itself be considered a task. By the induction hypothesis, the number of ways to perform \( P' \) is \( n_1 + n_2 + \cdots + n_k \). Since \( P \) is performed by performing either of the two tasks \( P' \) or \( T_{k+1} \), the number of ways to perform \( P \) is \( (n_1 + n_2 + \cdots + n_k) + n_{k+1} \). The result then follows by the Principle of Mathematical Induction.

Example 13.5

A student has a decision to make. She needs a minor for her academic program. To complete a minor in computer science, she can take any two of three certain courses next semester, which we denote by \( C_1, C_2 \), and \( C_3 \). On the other hand, she could decide on a minor in one of chemistry, physics, statistics or economics, in which case she would take an approved course in one of these areas next semester. How many choices does she have for next semester?

Solution

If the student decides to complete a minor in computer science next semester, she has three choices as she could take the courses \( C_1, C_2 \), the courses \( C_1, C_3 \) or the courses \( C_2, C_3 \). On the other hand, if she decides on a different minor, she has four choices. By the Addition Principle, she has a total of \( 3 + 4 = 7 \) choices.

The Addition Principle can also be stated in terms of sets. Let \( P \) be a procedure that consists of performing one of \( m \geq 2 \) tasks \( T_1, T_2, \ldots, T_m \), no two of which can be performed at the same time. If there are \( n_i \) ways to perform \( T_i \) for \( 1 \leq i \leq m \), then we saw by the Addition Principle that the number of ways of performing \( P \) is \( n_1 + n_2 + \cdots + n_m \).

\[ |A_1 \cup A_2 \cup \cdots \cup A_m| = |A_1| + |A_2| + \cdots + |A_m| = n_1 + n_2 + \cdots + n_m. \quad (13.2) \]

(See Exercise 13.9.)

SECTION 13.1 EXERCISES

13.1. A traveler wishes to take a trip from city A to city F. To do this, the traveler must first proceed through cities B, C, D in that order and then from D to F. If there are five ways to travel from A to B, four ways to travel from B to C, two ways to travel from C to D and three ways to travel from D to F, then how many ways are there for him to travel from A to F by one of these means of travel?
Chapter 13 Proofs in Combinatorics

13.2. A sequence \((\ell_1, \ell_2, \ell_3, \ell_4)\) of four letters is to be chosen from the 26 letters of the alphabet in such a way that \(\ell_2 \neq \ell_1, \ell_3 \neq \ell_2\) and \(\ell_4 \neq \ell_3\). How many such sequences of four letters are there?

13.3. In Section 1.6, we saw that \(|A \times B| = |A| \cdot |B|\) for every two finite sets \(A\) and \(B\).

(a) Prove by induction that for \(m \geq 2\) finite sets \(A_1, A_2, \ldots, A_m\),

\[|A_1 \times A_2 \times \cdots \times A_m| = |A_1| \cdot |A_2| \cdots |A_m|\]

(b) Determine \(|A_1 \times A_2 \times \cdots \times A_m|\) if \(A_k = \{1, 2, \ldots, k\}\) for \(k \in \{1, 2, \ldots, m\}\).

13.4. For a finite set \(A\) with \(n \geq 2\) elements, let \(Q\) be a partition of \(P(A)\) such that \(|X| = 2\) for each \(X \in Q\). Determine \(|Q \times Q|\).

13.5. Let \(A\) be a set with \(m\) elements and \(B\) a set with \(n\) elements.

(a) How many functions are there from \(A\) to \(B\)?

(b) If \(n \geq m\), how many one-to-one functions are there from \(A\) to \(B\)?

(c) If \(m > n\), how many one-to-one functions are there from \(A\) to \(B\)?

13.6. There are six ways to travel from Newark, New Jersey to Chicago by air, seven ways by car, three ways by train and ten ways by bus. In how many ways is it possible to travel from Newark to Chicago by exactly one of these means of travel?

13.7. A finite set \(A\) is partitioned into five subsets \(A_i\) \((1 \leq i \leq 5)\). Furthermore, each subset \(A_i\) is then partitioned into five subsets \(A_{ij}\) \((1 \leq j \leq 5)\). If \(|A_{ij}| = i + j\) for \(1 \leq i \leq 5\) and \(1 \leq j \leq 5\), then what is \(|A|\)?

13.8. Define \(A_k = \{2^kb : b\) is a positive odd integer and \(2^kb \mid 1000\}\) for \(0 \leq k \leq 3\).

(a) Determine \(|A_0 \cup A_1 \cup A_2 \cup A_3|\).

(b) In how many ways can a positive integer divisor \(m\) of 1000 be selected such that \(m\) is either odd or is a multiple of 8?

13.9. Prove by induction that for \(n \geq 2\) finite pairwise disjoint sets \(A_1, A_2, \ldots, A_n\),

\[|A_1 \cup A_2 \cup \cdots \cup A_n| = |A_1| + |A_2| + \cdots + |A_n|\]

13.10. An outcome of rolling a pair of dice consists of an ordered pair \((a, b)\), where each of \(a\) and \(b\) is one of \(1, 2, \ldots, 6\). The result of an outcome is \(a + b\).

(a) How many outcomes are possible in one roll of the two dice?

(b) In how many possible ways can a 4 or 7 result from a single roll of two dice?

13.11. When a coin is tossed, the outcome is either heads or tails. An experiment consists of tossing a coin \(n\) times in succession and recording the resulting sequence of outcomes.

(a) How many such sequences are possible?

(b) Determine the number of ways in which heads can occur exactly once in such a sequence.

(c) In how many ways can heads occur exactly \(n - 1\) times?

(d) In how many ways can heads occur at most once?

13.12. Let \(S = \{0, 1, 3, 4, 5, 7, 9\}\).

(a) How many 4-digit numbers are there where each digit is an element of \(S\) and no digits are repeated? (Note: The first digit of a 4-digit number is not 0.)

(b) How many of the numbers described in (a) are divisible by 5?

(c) How many of the numbers described in (a) are even?
13.2 THE PRINCIPLE OF INCLUSION-EXCLUSION

Recall that in terms of sets, the Addition Principle states that for any \( n \geq 2 \) pairwise disjoint finite sets, the cardinality of the union of these sets is the sum of the cardinalities of these sets. But what if the sets are not pairwise disjoint? Let’s first look at what happens when we have two sets that are not (pairwise) disjoint.

**The Principle of Inclusion-Exclusion (for two sets)**

For every two finite sets \( A \) and \( B \), where \( |A| = a \), \( |B| = b \) and \( |A \cap B| = c \),

\[
|A \cup B| = |A| + |B| - |A \cap B| = a + b - c.
\]

**Proof**

First, \( c \) of the \( a \) elements in \( A \) belong to \( B \) as well. Similarly, \( c \) of the \( b \) elements in \( B \) belong to \( A \). Therefore, \( |A| + |B| \) not only counts the elements that belong to exactly one of \( A \) and \( B \), it counts the \( c \) elements belonging to both of these sets twice. Consequently, \( |A \cup B| = a + b - c \).

We now illustrate this principle with the following two examples.

**Example 13.6**

Determine the number of integers in the set \( S = \{1, 2, \ldots, 25\} \) that are divisible by 2 or 3.

**Solution**

Let \( A \) and \( B \) be the subsets of \( S \) consisting of those integers in \( S \) divisible by 2 and 3, respectively. The answer to this problem is therefore \( |A \cup B| \). The set \( A \cap B \) then consists of those integers in \( S \) that are divisible by both 2 and 3 and so by 6 (see Theorem 12.16). Recall for a real number \( x \) that the floor \( \lfloor x \rfloor \) of \( x \) is the largest integer less than or equal to \( x \). Thus, the number of integers in \( S \) that are divisible by 2 is \( \lfloor 25/2 \rfloor = 12 \), that is, there are 12 even integers in \( S \). Similarly, there are \( \lfloor 25/3 \rfloor = 8 \) integers in \( S \) divisible by 3 and \( \lfloor 25/6 \rfloor = 4 \) integers in \( S \) divisible by 6. By the Principle of Inclusion-Exclusion, it follows that \( |A \cup B| = |A| + |B| - |A \cap B| = 12 + 8 - 4 = 16 \).

**Example 13.7**

We saw in Example 13.2(b) that there are \( 2^{10} = 1024 \) 10-bit strings. How many of these strings begin with three 0s or end with two 0s?

**Solution**

Let \( A \) be the set of 10-bit strings beginning with three 0s and \( B \) the set of 10-bit strings ending with two 0s. We seek the value \( |A \cup B| \). Since there are \( 2^5 \) 10-bit strings beginning with three 0s and ending with two 0s, it follows that \( |A \cap B| = 2^5 \) and so \( |A \cup B| = |A| + |B| - |A \cap B| = 2^7 + 2^8 - 2^5 = 128 + 256 - 32 = 352 \).

If the sets \( A \) and \( B \) in the Principle of Inclusion-Exclusion are disjoint, then \( c = 0 \) and \( |A \cup B| = |A| + |B| = a + b \), which returns us to the Addition Principle in the case of two sets. As expected, there is a general version of the Principle of Inclusion-Exclusion.
The Principle of Inclusion-Exclusion

For \( m \geq 2 \) finite sets \( A_1, A_2, \ldots, A_m \),
\[
|A_1 \cup A_2 \cup \cdots \cup A_m| = |A_1| + |A_2| + \cdots + |A_m| - \sum_{1 \leq i < j \leq m} |A_i \cap A_j| \\
+ \sum_{1 \leq i < j < k \leq m} |A_i \cap A_j \cap A_k| - \cdots \\
+ (-1)^{m+1}|A_1 \cap A_2 \cap \cdots \cap A_m|.
\]

In the case of three finite sets \( A, B, \) and \( C \), this more general Principle of Inclusion-Exclusion states that
\[
|A \cup B \cup C| = |A| + |B| + |C| - |A \cap B| - |A \cap C| - |B \cap C| + |A \cap B \cap C|. \tag{13.3}
\]

Proof of the Principle of Inclusion-Exclusion for three sets

One of the distributive laws for sets (Theorem 4.22, 3(b)) states that
\[ A \cap (B \cup C) = (A \cap B) \cup (A \cap C). \]

Observing further that
\[ (A \cap B) \cap (A \cap C) = A \cap B \cap C, \]
we see that
\[
|A \cup B \cup C| = |(A \cup (B \cup C))| = |A| + |B \cup C| - |A \cap (B \cup C)| \\
= |A| + |B| + |C| - |A \cap B| - |A \cap C| - |(A \cap B) \cup (A \cap C)| \\
= |A| + |B| + |C| - |A \cap B \cap C| - (|A \cap B| + |A \cap C| - |(A \cap B) \cap (A \cap C)|) \\
= |A| + |B| + |C| - |A \cap B| - |A \cap C| - |B \cap C| + |A \cap B \cap C|.
\]

Therefore, (13.3) holds.

The reason for the name of this principle is that to determine the number of elements in \( A_1 \cup A_2 \cup \cdots \cup A_m \), we add (include) the number of elements in \( A_1, A_2, \ldots, A_m \), subtract (exclude) the number of elements in the intersections of all pairs of these sets and then add back in the number of elements in the intersection of all triples of these sets, and so on.

The following example is similar to Example 13.6 but uses the Principle of Inclusion-Exclusion for three sets.

Example 13.8

Determine the number of integers in the set \( S = \{1, 2, \ldots, 100\} \) that are divisible by 2, 3 or 5.

Solution

Let \( A, B, \) and \( C \) be the subsets of \( S \) consisting of those integers in \( S \) divisible by 2, 3 and 5, respectively. The sets \( A \cap B, A \cap C, \) and \( B \cap C \) therefore consist of those integers in \( S \) that are divisible by 6, 10 and 15, respectively, while \( A \cap B \cap C \) consists of the integers in \( S \) divisible by 30. By the Principle of Inclusion-Exclusion,
\[
|A \cup B \cup C| = |A| + |B| + |C| - |A \cap B| - |A \cap C| - |B \cap C| + |A \cap B \cap C| \\
= 50 + 33 + 20 - 16 - 10 - 6 + 3 = 103 - 32 + 3 = 74.
\]

\[ \blacklozenge \]
13.2 The Principle of Inclusion-Exclusion

In Section 13.1, we initially stated the Addition Principle as the number of ways to perform a procedure consisting of tasks and then saw that this principle could be described in terms of sets. While we have stated the Principle of Inclusion-Exclusion in terms of sets and mentioned this is a more general principle than the Addition Principle, this principle could also be stated as a principle concerning the number of ways to perform a procedure consisting of tasks to be performed. We illustrate this with the next example, which deals with questions similar to what we saw in Example 13.4.

Example 13.9 Let \( S = \{1, 2, \ldots, 9\} \). Let \( T_1 \) be the task of selecting an even number from \( S \), \( T_2 \) the task of selecting an odd number from \( S \), \( T_3 \) the task of selecting an odd prime from \( S \) and \( T_4 \) the task of selecting a prime from \( S \).

(a) Let \( P' \) be the procedure consisting of performing any of the tasks \( T_1, T_2 \) and \( T_3 \). In how many ways can \( P' \) be performed?

(b) Let \( P'' \) be the procedure consisting of performing any of the tasks \( T_2, T_3 \) and \( T_4 \). In how many ways can \( P'' \) be performed?

Solution

(a) The procedure \( P' \) can be performed by selecting any integer from \( S \). Thus, the number of ways to perform \( P' \) is \(|S| = 9\). Also, there are four ways to perform \( T_1 \), five ways to perform \( T_2 \) and three ways to perform \( T_3 \). Furthermore, there are no ways to perform both \( T_1 \) and \( T_2 \), no ways to perform both \( T_1 \) and \( T_3 \) and three ways to perform both \( T_2 \) and \( T_3 \). Finally, there are no ways to perform \( T_1, T_2 \) and \( T_3 \) simultaneously. It then follows by the Principle of Inclusion-Exclusion that the number of ways to perform \( P' \) is \( 4 + 5 + 3 - 0 - 0 - 3 + 0 = 9 \).

(b) The procedure \( P'' \) can be performed by selecting any of the integers 1, 2, 3, 5, 7, 9 from \( S \). Therefore, the number of ways to perform \( P'' \) is \(|\{1, 2, 3, 5, 7, 9\}| = 6\). We also answer this question using the Principle of Inclusion-Exclusion. As in (a), there are five ways to perform \( T_2 \) and three ways to perform \( T_3 \). In addition, there are four ways to perform \( T_4 \). There are three ways to perform \( T_2 \) and \( T_3 \) simultaneously, three ways to perform both \( T_2 \) and \( T_4 \) and three ways to perform both \( T_3 \) and \( T_4 \). Furthermore, there are three ways to perform \( T_2, T_3 \) and \( T_4 \) simultaneously. Hence, the number of ways to perform \( P'' \) is \( 5 + 3 + 4 - 3 - 3 - 3 + 3 = 6 \).

Analysis The solution of Example 13.9 given above can also be expressed in terms of sets. If we let \( S_1 \) be the subset of \( S \) consisting of its even integers, \( S_2 \) the subset of \( S \) consisting of its odd integers, \( S_3 \) the subset of \( S \) consisting of the odd primes in \( S \) and \( S_4 \) the subset of \( S \) consisting of the primes in \( S \), then the number of ways that \( P' \) can be performed is

\[
|S_1 \cup S_2 \cup S_3| = |S_1| + |S_2| + |S_3| - |S_1 \cap S_2| - |S_1 \cap S_3| - |S_2 \cap S_3| + |S_1 \cap S_2 \cap S_3| = 4 + 5 + 3 - 0 - 0 - 3 + 0 = 9;
\]

while the number of ways that \( P'' \) can be performed is

\[
|S_2 \cup S_3 \cup S_4| = |S_2| + |S_3| + |S_4| - |S_2 \cap S_3| - |S_2 \cap S_4| - |S_3 \cap S_4| + |S_2 \cap S_3 \cap S_4| = 5 + 3 + 4 - 3 - 3 - 3 + 3 = 6.
\]
336 Chapter 13 Proofs in Combinatorics

SECTION 13.2 EXERCISES

13.13. (a) How many $(2n)$-bit strings begin with or end with $n$ 0s?
(b) How many $(2n)$-bit strings neither begin nor end with $n$ 0s?

13.14. Let $S = \{1, 2, \ldots, 110\}$. Observe that $110 = 2 \cdot 5 \cdot 11$. Let $A = \{d \in S : 2 \mid d\}$, $B = \{d \in S : 5 \mid d\}$ and $C = \{d \in S : 11 \mid d\}$.
(a) Determine $|A \cup B \cup C|$.
(b) Determine the number of elements of $S$ that are divisible by none of 2, 5 and 11.

13.15. Use the Principle of Inclusion-Exclusion to determine the number of bijective functions $f : \{1, 2, 3\} \to \{1, 2, 3\}$ for which $f(i) \neq i$ for $i = 1, 2, 3$.

13.16. Let $p$, $q$ and $r$ be distinct primes and let $n = pqr$. Determine the number of elements in $S = \{1, 2, \ldots, n\}$ that are divisible by at least one of $p$, $q$ and $r$.

13.17. Let $S = \{1, 2, \ldots, 100\}$ and let $T = \{f : S \to S\}$ be the set of all functions $f$ from $S$ to $S$. Define $A_i = \{f \in T : i \notin \text{range}(T)\}$, where $1 \leq i \leq 100$. Determine $|A_1 \cup A_2 \cup A_3|$.

13.18. Determine the number of solutions of the equation $x_1 + x_2 + x_3 = 4$ in which $x_1$, $x_2$ and $x_3$ are nonnegative integers and at least one of $x_1$, $x_2$ and $x_3$ is 0.

13.19. Find the number of integers $n$ with $1 \leq n \leq 10^{30}$ such that $n$ is neither a perfect square, a perfect cube nor a perfect fifth power.

13.20. Use the Principle of Inclusion-Exclusion to determine the number of positive integers in the set $S = \{1, 2, \ldots, 210\}$ that are divisible by at least one of 2, 3, 5 and 7.

13.21. A coin is flipped five times, resulting in the sequence $(a_1, a_2, a_3, a_4, a_5)$, where $a_i$ ($1 \leq i \leq 5$) is either H or T, depending on whether heads or tails occurs on the $i$th flip of the coin. Therefore, there are $2^5 = 32$ such sequences. Let $T_1$ be the task of obtaining H on the first and fifth flip of the coin, $T_2$ the task of obtaining H on the second, third and fourth flip of the coin and $T_3$ the task of obtaining H on the first, third and fifth flip of the coin. Let $P$ be the procedure consisting of performing at least one of $T_1$, $T_2$ and $T_3$. In how many ways can $P$ be performed?

13.3 THE PIGEONHOLE PRINCIPLE

Another principle that is encountered often in combinatorics concerns finite sets that are partitioned into a specific number of subsets. Here, at least one of these subsets must contain sufficiently many elements. The principle dealing with this is called the Pigeonhole Principle. The proof given below uses the fact that for a real number $x$, its ceiling $\lceil x \rceil$, which is the smallest integer greater than or equal to $x$, satisfies the inequalities

$$\lceil x \rceil - 1 < x \leq \lceil x \rceil. \quad (13.4)$$

**The Pigeonhole Principle**

If a set $S$ with $n$ elements is partitioned into $k$ subsets, then at least one of these subsets contains at least $\lceil n/k \rceil$ elements.

**Proof** Suppose that there is a partition $P = \{S_1, S_2, \ldots, S_k\}$ of $S$ into $k$ subsets such that every subset contains less than $\lceil n/k \rceil$ elements. Then $|S_i| \leq \lceil n/k \rceil - 1 < n/k$ for each subset $S_i$ ($1 \leq i \leq k$). By the Addition Principle,
The Pigeonhole Principle is believed to have been observed by the mathematician Johann Dirichlet in 1834 and for this reason, it is sometimes called Dirichlet’s principle.

Example 13.10 Each output of a computer program is a randomly selected integer. How many integers must be selected to guarantee that 10 of these integers will have the same remainder when divided by 6?

Solution What we wish to do is to select $n$ integers so that $\lceil n/6 \rceil \geq 10$. Since we want $n$ to be the smallest positive integer satisfying this inequality, it follows that $\lceil (n-1)/6 \rceil < 10$. This implies that $(n-1)/6 = 9$ and so $n-1 = 54$. Hence, $n = 55$.

We now describe three results whose proofs use the Pigeonhole Principle. Recall that every two consecutive integers are relatively prime.

Result 13.11 Let $n \in \mathbb{N}$. Every $(n+1)$-element subset of the $2n$-element set $A = \{1, 2, \ldots, 2n\}$ contains two relatively prime integers.

Proof Let $A_i = \{2i-1, 2i\}$ for $i = 1, 2, \ldots, n$. Thus, $\{A_1, A_2, \ldots, A_n\}$ is a partition of $A$. Since any $(n+1)$-element subset $B$ of $A$ must contain both integers in some set $A_i$, the two integers of $B$ belonging to $A_i$ are relatively prime.

Result 13.12 A total of 101 points $P_1, P_2, \ldots, P_{101}$ are placed in a $6 \times 8$ rectangle $R$. If a circle of radius 1 with center $P_i$ is constructed for each integer $i$ with $1 \leq i \leq 101$, then two of these circles must intersect.

Proof Divide the rectangle $R$ into 100 rectangles, where each is a $0.6 \times 0.8$ rectangle. The length of a diagonal in each of these rectangles is 1. Since there are 101 points and 100 rectangles, it follows by the Pigeonhole Principle that two of the points $P_i$ must lie in the same rectangle and so the circles centered at these two points must intersect.

Result 13.13 Let $a_1, a_2, \ldots, a_{2n}$ be a sequence of $2n \geq 2$ positive integers. If $\sum_{i=1}^{2n} a_i = 3n - 1$, then there is some set of consecutive integers in this sequence whose sum is $n$.

Proof For $j = 1, 2, \ldots, n$, let $s_j = \sum_{i=1}^{j} a_i$. Then

$$1 \leq s_1 < s_2 < \cdots < s_{2n} = 3n - 1.$$
By adding $n$ to each number in these inequalities, we have
\[ n + 1 \leq s_1 + n < s_2 + n < \cdots < s_{2n} + n = 4n - 1. \]

Since each of the $4n$ integers $s_1, s_2, \ldots, s_{2n}, s_1 + n, s_2 + n, \ldots, s_{2n} + n$ belongs to the set $\{1, 2, \ldots, 4n - 1\}$, it follows by the Pigeonhole Principle that two of these $4n$ integers are equal. Because $s_1, s_2, \ldots, s_{2n}$ are distinct as are $s_1 + n, s_2 + n, \ldots, s_{2n} + n$, it follows that $s_t = s_r + n$ where $1 \leq r < t \leq 2n$. Then $s_t - s_r = a_{r+1} + a_{r+2} + \cdots + a_t = n$. \hfill \Box

The following example is a variation of Example 13.10.

**Example 13.14** Each output of a computer program is a randomly selected integer. How many integers must be output to guarantee that either ten integers are multiples of 6, nine integers have a remainder of 1 when divided by 6, eight have a remainder of 2, seven have a remainder of 3, six have a remainder of 4 or five have a remainder of 5?

**Solution** Observe that the largest number of integers that can be output which would fail to satisfy this requirement would occur if we select nine with a remainder 0, eight with a remainder of 1, seven with a remainder of 2, six with a remainder of 3, five with a remainder of 4 and four with a remainder of 5. Thus, the minimum number of integers that can be output to satisfy this requirement is $1 + (9 + 8 + 7 + 6 + 5 + 4) = 40$. \hfill \Box

This example illustrates a principle that is more general than the Pigeonhole Principle.

**The Strong Pigeonhole Principle** If a set $S$ with $n$ elements is partitioned into $k$ subsets $S_1, S_2, \ldots, S_k$, where $|S_i| \geq n_i$ for $1 \leq i \leq k$, then each subset of $S$ with at least
\[ 1 + \sum_{i=1}^{k} (n_i - 1) \]

elements contains at least $n_i$ elements of $S_i$ for some integer $i$ with $1 \leq i \leq k$.

**Proof** Assume, to the contrary, that $S$ contains a subset $T$ with at least $1 + \sum_{i=1}^{k} (n_i - 1)$ elements but $T$ contains less than $n_i$ elements of $S_i$ for each integer $i$ with $1 \leq i \leq k$. Since the set $S$ is partitioned into the $k$ subsets $S_1, S_2, \ldots, S_k$, it follows that
\[ 1 + \sum_{i=1}^{k} (n_i - 1) \leq |T| \leq \sum_{i=1}^{k} (n_i - 1). \]

This is a contradiction. \hfill \Box

**Example 13.15** A box contains $k(k+1)/2$ balls, $k \in \mathbb{N}$, each of which is colored one of the $k$ colors $c_1, c_2, \ldots, c_k$. In particular, there are $i$ balls colored $c_i$ for $i = 1, 2, \ldots, k$. What is the minimum number of balls that must be removed from the box to guarantee that for some color $c_j$ ($1 \leq j \leq k$), all balls colored $c_j$ are removed from the box?
Section 13.3 Exercises

Solution  Since there are \( n_i = i \) balls colored \( c_i \) for \( 1 \leq i \leq k \), it follows by the Strong Pigeonhole Principle that

\[
1 + \sum_{i=1}^{k} (n_i - 1) = 1 + \sum_{i=1}^{k} (i - 1) = 1 + \frac{k(k - 1)}{2} = \frac{k^2 - k + 2}{2}
\]

balls must be removed from the box to guarantee that all balls colored \( c_j \) for some \( j \) (\( 1 \leq j \leq k \)) are removed from the box.

Analysis  Suppose, in the preceding example, that \( k = 3 \). Thus, the box contains six balls, one colored red, say, two colored blue and three colored green. The Strong Pigeonhole Principle tells us that four balls must be removed from the box to be certain that all balls of one of these three colors have been removed. Suppose then that four balls are removed from the box. If one of the four balls is red, then the one ball colored red has been removed. If not, then each of the four balls is colored blue or green. If two blue balls are removed, then all blue balls have been removed. On the other hand, if the two blue balls have not been removed, then at most one blue ball is removed and so the remaining three balls, all colored green, have been removed.

SECTION 13.3 EXERCISES

13.22. How large must the population of a community be to guarantee that two of its residents have the same three initials?

13.23. Suppose that the population of New York City exceeds seven million and that no person has more than one million hairs on his or her head. Show that there are at least eight people with the same number of hairs on their heads.

13.24. Prove that among any \( n + 1 \) people selected from a group of \( n \) women and their husbands, there is a married couple.

13.25. (a) Prove that if 51 integers are selected from the set \( S = \{1, 2, \ldots, 100\} \), then there must be two among these 51 selected integers such that one is divisible by the other.

(b) Show that the statement in (a) is false if only 50 integers are selected from the set \( S \).

13.26. Prove that in a group of 20 people, there are at least two with the same number of acquaintances in the group.

13.27. There are four cities where the distance in miles between every two cities is an integer. If the sum of the distances between all pairs of cities is 103 miles, prove that there exist two cities where the distance between them is at least 18 miles.

13.28. Prove that if 41 numbers are selected from the set \( S = \{1, 2, \ldots, 50\} \), then there must exist two among those chosen whose sum is 80.

13.29. Let \( f : A \to B \) be a function from a set \( A \) to a set \( B \), where \( |A| = m, |B| = n \) and \( m, n \in \mathbb{N} \). Prove that if \( m > kn \) for some \( k \in \mathbb{N} \), then some element of \( B \) is the image of at least \( k + 1 \) elements of \( A \).

13.30. A point \((a, b)\) in the plane is a lattice point if \( a \) and \( b \) are both integers. The midpoint of the line segment joining two lattice points \((a, b)\) and \((c, d)\) is the point \((\frac{a+c}{2}, \frac{b+d}{2})\).

(a) Given five lattice points in the plane, prove that there must exist a pair among them such that the midpoint of the line segment joining them is also a lattice point.

(b) Prove that the statement in (a) is false if only four lattice points are given.
Chapter 13  Proofs in Combinatorics

13.31. Show for every $n$ integers $x_1, x_2, \ldots, x_n$, that there exist integers $x_i$ and $x_j$ among them with $0 \leq i < j \leq n$ such that $x_{i+1} + x_{i+2} + \cdots + x_j \equiv 0 \pmod{n}$.

13.32. Let $S = \{000, 001, 002, \ldots, 999\}$ be the 1000-element set that consists of all 3-digit integers. Prove that every 28-element subset of $S$ contains at least two elements $a_1a_2a_3$ and $b_1b_2b_3$ such that $3 \mid (a_i - b_i)$ for $i = 1, 2, 3$.

13.33. For each positive integer $k$, let $R_k$ denote the $k$-digit integer where each digit is 1. For example, $R_1 = 1$, $R_2 = 11$ and $R_3 = 111$. Prove that there exists a positive integer $k$ such that $R_k$ is divisible by 1099.

13.34. Let $F$ be a collection of subsets of $S = \{1, 2, \ldots, n\}$, $n \geq 2$, such that if $X, Y \in F$, then $X \cap Y \neq \emptyset$. Prove that $|F| \leq 2^{n-1}$.

13.35. (a) Observe that $7^4 = 2401$ is an integer whose digits end with 01. Prove that there exists a power of 7 whose digits end with 001.

(b) Prove that if $p$ is a prime different from 2 and 5, then there exists a power of $p$ whose digits end with 001.

13.36. Prove, for every 7-element set $S$ of integers, that there exist at least five 2-element subsets of $S$ such that the difference of the integers in each set is a multiple of 3.

13.37. Let $n \in \mathbb{N}$. Prove that a sequence $s : a_1, a_2, \ldots, a_{n+1}$ of $n^2 + 1$ distinct real numbers either contains a subsequence of $n + 1$ numbers that is increasing or a subsequence of $n + 1$ numbers that is decreasing. (A sequence $s' : b_1, b_2, \ldots, b_r$ is increasing if $b_1 < b_2 < \cdots < b_r$ and decreasing if $b_1 > b_2 > \cdots > b_r$. A sequence $s''$ of the form $s'' : b_{k_1}, b_{k_2}, \ldots, b_{k_p}$, where $1 \leq k_1 < k_2 < \cdots < k_p \leq r$ is called a subsequence of $s$. For example, $s''' : b_3, b_5, b_6, b_8$ is a subsequence of $s' : b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8$.) [Hint: Use a proof by contradiction and for $1 \leq k \leq n^2 + 1$, let $t_k$ denote the length of a longest increasing subsequence of $s$ beginning with $a_k$.]

13.38. A set $S$ consists of 60 integers, namely ten primes that are at least 5, the integers $2^k$ for $1 \leq k \leq 20$ and the integers $3^k$ for $1 \leq k \leq 30$. How many integers must belong to a subset of $S$ to guarantee that

(a) there are at least ten even integers or at least fifteen integers divisible by 3?
(b) there are at least five primes, at least five even integers and at least five integers divisible by 3?

13.39. If a drawer contains five nickels, ten dimes and 25 quarters, then what is the minimum number of coins that must be selected from the drawer to be certain that all coins of the same denomination have been selected?

13.40. A box contains one red ball, one blue ball, two green balls and two yellow balls. What is the minimum number of balls that must be removed from the box to be certain that all balls of one of the four colors have been removed?

13.4 PERMUTATIONS AND COMBINATIONS

Many of the theorems and problems encountered in combinatorics deal with the number of certain types of subsets that a given set may have or the number of arrangements or ordered lists of their elements. It is questions of this nature that we will consider now. The fundamental concepts concerning this are permutations and combinations.

By a permutation of a nonempty set $S$ is meant an arrangement or ordered list of the elements of $S$.

Example 13.16  Determine the number of permutations of the set $S = \{a, b, c, d\}$.
13.4 Permutations and Combinations

Solution One permutation of $S$ is $a, b, c, d$, which is often written as $abcd$; while another permutation of $S$ is $dcba$. In fact, all permutations of the set $S$ are listed below:

$$\begin{align*}
abcd & \quad bacd & \quad cabd & \quad dabc \\
abdc & \quad badc & \quad cadb & \quad dacb \\
acbd & \quad bcad & \quad cbad & \quad dbac \\
acdb & \quad bcda & \quad cbda & \quad dbca \\
adb & \quad bdac & \quad cdab & \quad dcab \\
adc & \quad bdca & \quad cdba & \quad dcba
\end{align*}$$

Consequently, the total number of permutations of $S$ is 24.

There is, however, a simple method to determine the number of permutations of $S$ without listing all of the permutations and which will be considerably more practical for sets having a larger number of elements. A permutation of $S$ is obtained by ordering the four elements of $S$ in some manner, say

$$\begin{align*}
\quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \quad \ Quad
the number of permutations of $S_2$ is $6! = 720$. For $S_3$, 13579 and 59317 are permutations. Since $|S_3| = 5$, the number of permutations of $S_3$ is $5! = 120$. ♦

The term *permutation* was encountered in Chapter 10, where functions were discussed. In particular, for a nonempty set $A$, a bijective function $f : A \rightarrow A$ was called a permutation on (or of) $A$. For example, suppose that $A$ is a finite set, say $A = \{a, b, c, d, e\}$. Then the function $f : A \rightarrow A$, defined by

$$f(a) = c, \ f(b) = d, \ f(c) = a, \ f(d) = e, \ f(e) = b$$

is a permutation of $A$. This function can also be expressed as

$$f = \{(a, c), (b, d), (c, a), (d, e), (e, b)\}.$$ 

In particular, once we know the images of $a$, $b$, $c$, $d$ and $e$, we know the permutation $f$. In this case, the images are $c$, $d$, $a$, $e$, $b$ (or $cdaeb$), which is, therefore, an arrangement of the elements of $A$. Hence, these two uses of the term “permutation” are equivalent.

Suppose, for a finite nonempty set $A$, that we wish to determine the number of ordered lists of some fixed number of elements of $A$. The next example deals with this situation.

**Example 13.18**

Determine the number of ordered lists of two elements of the set $S = \{1, 2, 3, 4, 5\}$.

**Solution**

Since there are 5 possible choices for the first element in the list, and once this element has been selected, there are 4 possible elements for the second element in the list, it follows by the Multiplication Principle that there are $5 \cdot 4 = 20$ ordered lists of two elements in the set $S$. These 20 lists are shown below:

$$12, 21, 31, 41, 51$$
$$13, 23, 32, 42, 52$$
$$14, 24, 34, 43, 53$$
$$15, 25, 35, 45, 54$$

Of course, we were only asked for the number of such ordered lists, not the lists themselves. ♦

In general, if we want to know the number of ordered lists of $r$ elements of an $n$-element set $S$, where $1 \leq r \leq n$, we are considering sequences

$$\begin{array}{cccccc} \text{term 1} & \text{term 2} & \text{term 3} & \cdots & \text{term } r-1 & \text{term } r \end{array}$$

of length $r$ consisting of all possible orderings for every choice of $r$ elements of $S$. There are $n$ choices for the first term of the sequence. Once the first term has been chosen, there are $n-1$ choices for the second term and $n-2$ choices for the third term. Continuing in this manner, we see that there are $n-(r-1)+1$ choices for term $r-1$ and finally, $n-r+1$ choices for the final term $r$. By the Multiplication Principle, there are

$$n(n-1)(n-2)\cdots(n-r+2)(n-r+1) \quad (13.5)$$
Possible orderings of $r$ elements of $S$. Multiplying the expression in (13.5) by $(n - r)!/(n - r)!$, we have

$$n(n - 1)(n - 2) \cdots (n - r + 2)(n - r + 1) \frac{(n - r)!}{(n - r)!} = \frac{n!}{(n - r)!}.$$  

An ordered list of $r$ elements of an $n$-element set $S$ is referred to as an $r$-permutation of $S$. The number of $r$-permutations of an $n$-element set is commonly denoted by $P(n, r)$. The next theorem summarizes what we just observed.

**Theorem 13.19**

For integers $r$ and $n$ with $1 \leq r \leq n$, the number of $r$-permutations of an $n$-element set is

$$P(n, r) = \frac{n!}{(n - r)!}.$$  

In Example 13.18, we saw that there are 20 ordered lists of two elements in the set $\{1, 2, 3, 4, 5\}$, which illustrates the fact that

$$P(5, 2) = \frac{5!}{(5 - 2)!} = \frac{5!}{3!} = \frac{5 \cdot 4 \cdot 3!}{3!} = 20.$$  

For the case when $r = n$, an $n$-permutation is an ordered list of all $n$ elements of an $n$-element set. In other words, an $n$-permutation of an $n$-element set is simply a permutation of the set. By Theorem 13.19, the number of permutations of an $n$-element set is

$$P(n, n) = \frac{n!}{(n - n)!} = \frac{n!}{0!} = n!,$$

recalling that $0! = 1$.

**Example 13.20**

Let $S = \{1, 2, 3, 4, 5, 6\}$.

(a) Give two examples of permutations of $S$.

(b) How many permutations of $S$ are there?

(c) Give two examples of 2-permutations of $S$.

(d) How many 2-permutations of $S$ are there?

(e) Give two examples of 4-permutations of $S$.

(f) How many 4-permutations of $S$ are there?

**Solution**

(a) 123456 and 256314.

(b) $P(6, 6) = 6! = 720$.

(c) 13 and 63.

(d) $P(6, 2) = 6!/4! = (6 \cdot 5 \cdot 4!)/4! = 30$.

(e) 1256 and 6342.

(f) $P(6, 4) = 6!/2! = 360$.

When discussing permutations or $r$-permutations of a set $S$, we are referring to sequences, arrangements or ordered lists of elements of $S$. That is, the order in which the
Example 13.21 Let $S = \{a, b, c, d, e\}$.

(a) How many subsets of $S$ contain exactly two elements?
(b) How many subsets of $S$ contain exactly three elements?

Solution

(a) The 2-element subsets of $S$ are given below:

$\{a, b\}, \{a, c\}, \{a, d\}, \{a, e\}, \{b, c\}, \{b, d\}, \{b, e\}, \{c, d\}, \{c, e\}, \{d, e\}$.

Therefore, there are ten 2-element subsets of $S$.

(b) The 3-element subsets of $S$ are

$\{a, b, c\}, \{a, b, d\}, \{a, b, e\}, \{a, c, d\}, \{a, c, e\}, \{a, d, e\}, \{b, c, d\}, \{b, c, e\}, \{b, d, e\}, \{c, d, e\}$.

So the number of 3-element subsets of $S$ is 10 as well.

Although we answered the questions asked in Example 13.21 by listing all 2-element subsets and all 3-element subsets of the set $S = \{a, b, c, d, e\}$, this method would not be practical for larger sets. Furthermore, the method we used makes it too easy to make mistakes, as we could inadvertently miss some subset we should have included or perhaps list some subsets more than once. There is, however, another approach to answer these questions.

For integers $r$ and $n$ with $0 \leq r \leq n$, an $r$-element subset of an $n$-element set $S$ is referred to as an $r$-combination or an $r$-selection of $S$. Therefore, an $r$-combination is an unordered list of $r$ elements.

The number of $r$-combinations of an $n$-element set is denoted by $C(n, r)$ or by $\binom{n}{r}$. The notation $\binom{n}{r}$ is ordinarily read as “$n$ choose $r$” as we are selecting or choosing $r$ elements from an $n$-element set. Even though $C(n, r)$ and $\binom{n}{r}$ represent the same number, you should be familiar with both as both are common. The notation $\binom{n}{r}$ is much more common in advanced mathematics, however.

Let $A$ be an $n$-element set for some positive integer $n$ and consider some $r$-element subset $B$, where $1 \leq r < n$, say $A = \{a_1, a_2, \ldots, a_n\}$ and $B = \{a_1, a_2, \ldots, a_r\}$. In this case, the elements $a_{r+1}, a_{r+2}, \ldots, a_n$ do not belong to $B$. Since $B$ is a set, the order in which the $r$ elements of $B$ are listed does not matter. However, every ordering of the elements of $B$ produces a permutation of $B$. Since $|B| = r$, there are $r!$ permutations of $B$. Consequently, since there are $C(n, r)$ $r$-element subsets of $A$, it follows that $r!C(n, r)$ is the total number of $r$-permutations of $A$. Because this number is $P(n, r) = n!/(n - r)!$, it follows that

$$P(n, r) = \frac{n!}{(n - r)!} = r!C(n, r)$$

and so

$$C(n, r) = \frac{n!}{r!(n - r)!}.$$
Therefore,

\[ C(6, 2) = \binom{6}{2} = \frac{6!}{2!4!} = 15 = \frac{6}{4! \cdot 2!} = C(6, 4) \text{ and} \]

\[ C(5, 2) = \binom{5}{2} = \frac{5!}{2!3!} = 10 = \frac{5!}{3! \cdot 2!} = C(5, 3). \]

Thus, it was not surprising that there are both ten 2-element subsets and ten 3-element subsets of the set \( S = \{a, b, c, d, e\} \) in Example 13.21. Furthermore, we see that the questions there can be answered more readily by computing \( C(5, 2) = C(5, 3) \). That \( C(5, 2) = C(5, 3) \) and \( C(6, 2) = C(6, 4) \) are special cases of a more general observation.

**Theorem 13.22** For integers \( r \) and \( n \) with \( 0 \leq r \leq n \),

\[ C(n, r) = C(n, n - r) \text{ or } \binom{n}{r} = \binom{n}{n-r}. \]

**Proof** We give two proofs of this fact. First,

\[ C(n, r) = \frac{n!}{r!(n-r)!} = \frac{n!}{(n-r)!r!} = \frac{n!}{(n-r)!(n-(n-r))!} = C(n, n-r). \]

Second, recall that \( C(n, r) \) represents the number of \( r \)-element subsets of an \( n \)-element set, say \( S \). For each \( r \) elements that are selected for a subset of \( S \), we are selecting \( n-r \) elements that do not belong to this subset. Since the number of ways of selecting \( n-r \) elements of \( S \) is \( C(n, n-r) \), it follows that \( C(n, r) = C(n, n-r) \).

The second proof given in Theorem 13.22 is an example of what is commonly called a combinatorial proof. A combinatorial proof is a proof that depends on counting arguments, often counting the same set of objects in two different ways rather than algebraic manipulation. The following result provides another example of a combinatorial proof.

**Theorem 13.23** For every positive integer \( n \),

\[ \binom{n}{0} + \binom{n}{1} + \binom{n}{2} + \cdots + \binom{n}{n-1} + \binom{n}{n} = 2^n. \]

**Proof** Let \( S \) be an \( n \)-element set. We have already seen that there are \( 2^n \) subsets of \( S \). For each integer \( r \) with \( 0 \leq r \leq n \), \( \binom{n}{r} \) counts the number of \( r \)-element subsets of \( S \). Therefore,

\[ \binom{n}{0} + \binom{n}{1} + \binom{n}{2} + \cdots + \binom{n}{n-1} + \binom{n}{n} \]

counts all subsets of \( S \), which, therefore, equals \( 2^n \). (See Theorem 6.16.)

For integers \( r \) and \( n \) with \( 0 \leq r \leq n \), we have already seen by Theorem 13.22 that \( \binom{n}{r} = \binom{n}{n-r} \). We now make some observations about the numbers \( \binom{n}{r} \) for some specific
values of $r$. Let $S$ be an $n$-element set. First,\
\[
\binom{n}{0} = \binom{n}{n} = \frac{n!}{n!0!} = 1,
\]
which says that there is exactly one subset of $S$ with no elements and exactly one subset of $S$ with $n$ elements. These subsets are, of course, $\emptyset$ and $S$, respectively. Because\
\[
\binom{n}{1} = \frac{n!}{1!(n-1)!} = \frac{n \cdot (n-1)!}{(n-1)!} = n,
\]
there are exactly $n$ 1-element subsets of $S$, as expected. Also, $\binom{n}{n-1}$ and so there are exactly $n$ subsets of $S$ that consist of $n-1$ elements. The numbers $\binom{n}{2}$ occur frequently in combinatorics as well. For $n \geq 2$,\
\[
C(n, 2) = \binom{n}{2} = \frac{n!}{2!(n-2)!} = \frac{n(n-1)(n-2)!}{2 \cdot (n-2)!} = \frac{n(n-1)}{2}.
\]
That is, to compute $C(n, 2)$ for an integer $n \geq 2$, we divide the product of $n$ and $n-1$ by 2. For example,\
\[
\binom{4}{2} = \frac{4 \cdot 3}{2} = 6, \quad \binom{5}{2} = \frac{5 \cdot 4}{2} = 10 \quad \text{and} \quad \binom{6}{2} = \frac{6 \cdot 5}{2} = 15.
\]
Some other specific examples of $\binom{n}{r}$ are\
\[
\binom{6}{3} = \frac{6!}{3!3!} = \frac{6 \cdot 5 \cdot 4 \cdot 3!}{6 \cdot 3!} = 20 \quad \text{and} \quad \binom{8}{5} = \frac{8!}{5!3!} = \frac{8 \cdot 7 \cdot 6 \cdot 5!}{5! \cdot 6} = 56.
\]

**Example 13.24** We saw in Example 13.2(b) that there are $2^{10} = 1024$ 10-bit strings.

*(a)* Give an example of three 10-bit strings containing exactly six 1s.

*(b)* How many 10-bit strings contain exactly six 1s?

**Solution** *(a)* 1011001101, 1110000111, 1100110011.

*(b)* To determine the number of 10-bit strings containing exactly six 1s, it is sufficient to determine the number of possible positions where 1 can be placed. For example, in the first 10-bit string in (a), the 1s are placed in terms 1, 3, 4, 7, 8 and 10. Hence, the number of 10-bit strings containing exactly six 1s is\
\[
C(10, 6) = \binom{10}{6} = \frac{10!}{6!4!} = \frac{10 \cdot 9 \cdot 8 \cdot 7 \cdot 6!}{6!4!} = \frac{10 \cdot 9 \cdot 8 \cdot 7}{4 \cdot 3 \cdot 2 \cdot 1} = 210.
\]

The following example uses both permutations and combinations.

**Example 13.25** A computer program randomly outputs an ordered list $L$ of four elements from the set $S = \{1, 2, \ldots, 10\}$ followed by a 3-element subset of the elements of $S$ not in $L$. What is the number of possible outputs of this program?

**Solution** This number is $P(10, 4) \cdot C(6, 3) = (5040)(20) = 100,800.$
SECTION 13.4 EXERCISES

13.41. Let \( S = \{1, 2, \ldots, 12\} \).

(a) Determine the number of 8-permutations of \( S \) in which 7 and 8 do not appear.

(b) Determine the number of 8-permutations of \( S \) in which 7 and 8 do not appear consecutively in either order.

(c) Determine the number of 9-permutations of \( S \) that contain 6.

13.42. (a) Express the number of one-to-one functions from \( A = \{1, 2, \ldots, 6\} \) to \( B = \{1, 2, \ldots, 10\} \) as \( P(n, r) \) for some integers \( n \) and \( r \).

(b) For positive integers \( a \) and \( b \) with \( a \leq b \), determine a generalization of the problem in (a) by expressing the number of one-to-one functions from a set \( A \) to a set \( B \) where \( |A| = a \) and \( |B| = b \).

13.43. By an \( n \)-letter word is meant a sequence of length \( n \), each term of which is one of the 26 letters of the English alphabet. Here we assume that a, e, i, o, u are the five and only vowels, while the remaining 21 letters are consonants. Determine the number of 15-letter words that contain exactly two, three or five distinct vowels but where consonants may be repeated.

13.44. (a) Determine the number of 17-letter words (see Exercise 13.43) with distinct letters containing \( x \), \( y \) and \( z \).

(b) How many of the 17-letter words in (a) have \( x \), \( y \) and \( z \) appearing in three consecutive positions in some order?

(c) How many of the 17-letter words in (a) do not have \( x \), \( y \) and \( z \) occupying three consecutive positions?

13.45. Let \( S = \{1, 2, \ldots, n\} \), where \( n \in \mathbb{N} \).

(a) Determine \( n \) if one-fifth of the 4-element subsets of \( S \) contain \( n \).

(b) Determine \( n \) if one-eleventh of the 4-element subsets of \( S \) contain both 1 and 2.

13.46. How many triangles are determined by \( n \geq 3 \) points in the plane, no three of which lie on the same line?

13.47. Let \( S = \{1, 2, \ldots, n\} \) and let \( m \) and \( r \) be integers such that \( 1 \leq r < m < n \). For an \( r \)-element subset \( A \) of \( S \), determine the number of \( m \)-permutations of \( S \) in which all elements of \( A \) appear.

13.48. Let \( S = \{1, 2, 3, 4, 5\} \). Recall that a bijection \( f : S \rightarrow S \) is called a permutation of \( S \). A permutation \( f \) of \( S \) is said to fix \( i \in S \) if \( f(i) = i \). How many permutations of \( S \) fix exactly one element of \( S \)?

13.49. An experiment consists of tossing an ordinary coin \( n \) times in succession and recording the resulting sequence of outcomes.

(a) In how many ways can exactly \( k \) heads occur?

(b) In how many ways can at most \( k \) heads occur, where \( 1 \leq k \leq n \)?

(c) In how many ways can more than \( k \) heads occur, where \( 1 \leq k \leq n \)?

13.50. Prove that \( \left( \frac{2n}{n} \right) < 4^n \) for every positive integer \( n \).

13.51. Prove that \( \left( \frac{2}{2} \right) + \left( \frac{2}{5} \right) + \left( \frac{2}{8} \right) + \cdots + \left( \frac{2}{x} \right) = \frac{n(n+1)(4n-1)}{6} \) for every positive integer \( n \). (See Results 6.4 and 6.5.)

13.52. Let \( A = \{1, 2, \ldots, m\} \) and \( B = \{1, 2, \ldots, n\} \), where \( n > m \).

(a) How many \( m \)-element subsets of \( A \times B \) contain no elements (ordered pairs) with the same first coordinate?

(b) How many \( m \)-element subsets of \( A \times B \) contain no elements with the same second coordinate?

(c) How many \( m \)-element subsets of \( A \times B \) contain no elements with the same first coordinate or the same second coordinate?
13.53. Let $A$, $B$ and $C$ be pairwise disjoint sets where $|A| = 10$, $|B| = 8$ and $|C| = 6$. Determine the number of 10-permutations of $A \cup B \cup C$ that contain exactly eight elements of $A$.

13.54. Let $A = \{1, 2, \ldots, 10\}$ and $B = \{11, 12, \ldots, 25\}$. Determine the number of 15-permutations of $A \cup B$ in which five elements belong to $A$ and ten belong to $B$.

13.55. Let $k$, $r$ and $n$ be nonnegative integers such that $k + r \leq n$. Give a combinatorial proof of each of the following.

(a) \((n+r)\binom{k}{r} = \binom{n}{2r}\binom{k}{r}\)

(b) \(\binom{n}{k+r} = \binom{n}{k}\binom{n-k}{r}\)

13.5 THE PASCAL TRIANGLE

Blaise Pascal (1623–1662) was a French mathematician and scientist who made important contributions to a variety of scholarly areas during the 17th century. He, along with Pierre de Fermat, have been credited with developing probability as a theoretical area of mathematics. As a teenager, Pascal became interested in calculating machines, which led to his invention of a mechanical calculator. In fact, the computer programming language Pascal, named for him, was popular and widely used during the late 1970s and 1980s.

What Pascal may be best known for, however, is a table of numbers expressed in a triangular manner that he described in his work Treatise on the Arithmetical Triangle (English translation from French). The first several numbers in Pascal’s triangular array are shown in Figure 13.3.

```
1 1 1 1 1 1
1 2 3 4 5 6 ...
1 3 6 10 15 ...
1 4 10 20 ...
1 5 15 ...
1 ...
```

Figure 13.3 Pascal’s triangular array of numbers

Although Pascal described these numbers as they appear in Figure 13.3, these are typically displayed as shown in Figure 13.4, which is referred to as the Pascal triangle (also commonly called Pascal’s triangle). While this triangular array of numbers is named for the 17th century mathematician Pascal, he was not the first to recognize this “triangle.” There are, in fact, references to portions of this triangle during the 11th century. In fact, Pascal was not the first European to study these numbers and never claimed to be. The numbers in the Pascal triangle are believed to have entered Europe by way of Arabia from China.

You may recognize some of the numbers in the Pascal triangle in Figure 13.4 as those you have seen recently. For example, the numbers in row 4 are

\[1 = \binom{4}{0}, \quad 4 = \binom{4}{1}, \quad 6 = \binom{4}{2}, \quad 4 = \binom{4}{3}, \quad 1 = \binom{4}{4}.\]

In fact, for $r = 0, 1, \ldots, n$, the $(r + 1)$st number in row $n$ is $\binom{n}{r} = C(n, r)$. Therefore, the Pascal triangle can be expressed as shown in Figure 13.5.
The Pascal Triangle

13.5 The Pascal Triangle

row 0  1
row 1  1  1
row 2  1  2  1
row 3  1  3  3  1
row 4  1  4  6  4  1
row 5  1  5  10  10  5  1
row 6  1  6  15  20  15  6  1

... ... ... ... ... ...

Figure 13.4 The Pascal triangle

row 0  \binom{0}{0}
row 1  \binom{1}{0} \binom{1}{1}
row 2  \binom{2}{0} \binom{2}{1} \binom{2}{2}
row 3  \binom{3}{0} \binom{3}{1} \binom{3}{2} \binom{3}{3}
row 4  \binom{4}{0} \binom{4}{1} \binom{4}{2} \binom{4}{3} \binom{4}{4}
row 5  \binom{5}{0} \binom{5}{1} \binom{5}{2} \binom{5}{3} \binom{5}{4} \binom{5}{5}
row 6  \binom{6}{0} \binom{6}{1} \binom{6}{2} \binom{6}{3} \binom{6}{4} \binom{6}{5} \binom{6}{6}

... ... ... ... ... ...

Figure 13.5 Another view of the Pascal triangle

Returning to the Pascal triangle as shown in Figure 13.4, you might notice that each interior number of the triangle (those not along the edges of the triangle) is the sum of the two numbers just above it. Expressing the numbers as given in Figure 13.5, this suggests that

\[ \binom{n}{r} = \binom{n-1}{r-1} + \binom{n-1}{r}. \]

We show that this statement (named for Pascal) is, in fact, true in general.

**Theorem 13.26 (Pascal’s Identity)** For every two integers \( r \) and \( n \) with \( 1 \leq r \leq n - 1 \),

\[ \binom{n}{r} = \binom{n-1}{r-1} + \binom{n-1}{r}. \]

**Proof** We provide a combinatorial proof of this statement. Let \( A \) be an \( n \)-element set, say \( A = \{a_1, a_2, \ldots, a_n\} \). Then \( \binom{n}{r} \) represents the number of \( r \)-element subsets of \( A \). Next, let
Chapter 13 Proofs in Combinatorics

$A' = \{a_1, a_2, \ldots, a_{n-1}\}$. Then $A = A' \cup \{a_n\}$. Of the \(\binom{n}{r}\) $r$-element subsets of $A$, some do not contain $a_n$, while others do. Since $|A'| = n - 1$, there are $\binom{n-1}{r}$ $r$-element subsets of $A$ that do not contain $a_n$. For those $r$-element subsets of $A$ that contain $a_n$, $r - 1$ of the elements belong to $A'$. Since there are $\binom{n-1}{r-1}$ $(r - 1)$-element subsets of $A'$, it follows by the Addition Principle that the number of $r$-element subsets of $S$ is $\binom{n-1}{r-1} + \binom{n-1}{r}$ and so $\binom{n}{r} = \binom{n-1}{r-1} + \binom{n-1}{r}$.

The Pascal triangle has a number of interesting features. For example, returning to Figure 13.3, we might observe that each number not in the first row is the sum of the number immediately above it and the numbers to the left of this. For example, the number 20 in the 4th row equals $1 + 3 + 6 + 10$. In the Pascal triangle expressed in Figure 13.5, this says that

$$\binom{6}{3} = \binom{2}{0} + \binom{3}{1} + \binom{4}{2} + \binom{5}{3} \quad (13.6)$$

or, by Theorem 13.22,

$$\binom{6}{3} = \binom{2}{2} + \binom{3}{2} + \binom{4}{2} + \binom{5}{2}. \quad (13.7)$$

These are the numbers in the Pascal triangle shown in Figure 13.6. Because of the pattern of this list of numbers in (13.6) and (13.7), this illustrates what is commonly called the Hockey Stick Theorem.

Theorem 13.27 (The Hockey Stick Theorem) For every two integers $r$ and $n$ with $0 \leq r \leq n$,

$$\binom{n+1}{r+1} = \binom{n}{r} + \binom{n+1}{r+1} + \binom{n+2}{r} + \cdots + \binom{n}{r}. \quad (13.7)$$
13.5  The Pascal Triangle  351

**Proof**  The number of bit strings of length \( n + 1 \) (sequences with \( n + 1 \) terms, each of which is 0 or 1) containing exactly \( r + 1 \) 1s is \( \binom{n+1}{r+1} \). Each such string therefore has the appearance shown below

\[
\begin{array}{ccccccc}
\text{term 1} & \text{term 2} & \cdots & \text{term } r+1 & \cdots & \text{term } n & \text{term } n+1 \\
\end{array}
\]

where there is either 0 or 1 at each position. Because there are \( r + 1 \) 1s in the sequence, the last 1 appears either at position \( r + 1 \) or to the right of that position. If the final 1 should happen to appear at position \( r + 1 \), then the remaining \( r \) 1s appear in positions 1 through \( r \). Then the number of ways of selecting \( r \) of these \( r \) positions for the \( r \) 1s is \( \binom{r}{r} \). If the final 1 appears in position \( r + 2 \), then the remaining \( r \) 1s appear in positions 1 through \( r + 1 \) and the number of ways of selecting \( r \) of these \( r + 1 \) positions for the remaining \( r \) 1s is \( \binom{r+1}{r} \). Continuing in this manner, we obtain the desired conclusion that

\[
\binom{n+1}{r+1} = \binom{r}{r} + \binom{r+1}{r} + \binom{r+2}{r} + \cdots + \binom{n}{r}.
\]

Applying the Hockey Stick Theorem for the case \( r = 1 \), we have

\[
\binom{n+1}{2} = \binom{1}{1} + \binom{2}{1} + \binom{3}{1} + \cdots + \binom{n}{1}
\]
or

\[
\frac{n(n+1)}{2} = 1 + 2 + 3 + \cdots + n,
\]

a statement we earlier verified by induction (see Chapter 6).

Another interesting feature of the Pascal triangle is shown in Figure 13.7. Suppose that we start with the leftmost element of row \( n \), namely \( \binom{n}{0} \). We now move three places to the right, from a blank space to \( \binom{n}{1} \) to another blank space. The element just above this is \( \binom{n-1}{1} \). We continue this, adding these numbers until we have moved off the triangle, obtaining either \( \binom{n}{0} + \binom{n-1}{1} + \cdots + \binom{k}{1} \) if \( n = 2k \) or \( \binom{n}{0} + \binom{n}{1} + \cdots + \binom{k+1}{1} \) if \( n = 2k + 1 \). This resulting sum is the \((n+1)\)st Fibonacci number \( F_{n+1} \) (see Exercise 13.62).

352 Chapter 13 Proofs in Combinatorics

SECTION 13.5 EXERCISES

13.56. Use an appropriate identity to simplify the following.
(a) \( \binom{12}{4} + \binom{12}{5} \)
(b) \( \binom{5}{5} + \binom{6}{5} + \binom{7}{5} + \cdots + \binom{11}{5} \)
(c) \( \binom{10}{0} + \binom{10}{1} + \binom{10}{2} + \cdots + \binom{10}{10} \).

13.57. Consider the third diagonal of the Pascal Triangle in Figure 13.4 that proceeds downward from right to left. The sums of the first three successive pairs of terms are \( 1 + 3 = 2^2 \), \( 3 + 6 = 3^2 \) and \( 6 + 10 = 4^2 \).
(a) Express each of these sums using the notation of combinations.
(b) Show that \( \binom{n}{2} + \binom{n+1}{2} = \binom{n}{1} \) for every integer \( n \geq 2 \).
(c) Explain why \( \binom{n}{2} + \binom{n+1}{2} = \binom{2n+1}{2} - n(n+1) \) for every integer \( n \geq 2 \).

13.58. Prove that \( \sum_{k=0}^{n} \binom{n}{k} = \binom{n+1}{k+1} \) for all integers \( k \) and \( n \) with \( 0 \leq k \leq n \).

13.59. Prove, for all integers \( n \geq 3 \), that
\[ \sum_{k=3}^{n} k(k-1)(k-2) = 3! \binom{n+1}{4}. \]

13.60. Prove, for nonnegative integers \( k \) and \( n \), that
\[ \sum_{k=0}^{n} \frac{(k+n)!}{k!} = \frac{(2n+1)!}{(n+1)!} \]

13.61. (a) For an integer \( k \geq 3 \), show that \( k^3 \) can be expressed as a linear combination of \( \binom{3}{3} \), \( \binom{3}{2} \) and \( \binom{3}{1} \). That is, find integers \( a \), \( b \) and \( c \) such that \( k^3 = a \binom{3}{3} + b \binom{3}{2} + c \binom{3}{1} \).
(b) Use the result in (a) and the Hockey Stick Theorem to determine a formula for the sum
\[ 1^3 + 2^3 + \cdots + n^3 \]
for each positive integer \( n \).
(c) Use the result in (b) to show that \( 6 \binom{n+2}{4} = \binom{n+4}{2} - \binom{n+1}{2} \).

13.62. It was illustrated for \( n = 0, 1, \ldots, 6 \) in Figure 13.7 that the sum
\[ \binom{n}{0} + \binom{n-1}{1} + \cdots + \binom{3}{3} \]
according to whether \( n \) is even or \( n \) is odd (and so \( n = 2k \) or \( n = 2k + 1 \), respectively) is the \( (n+1) \)st Fibonacci number \( F_{n+1} \). Verify this for every nonnegative integer \( n \).

13.6 THE BINOMIAL THEOREM

One of the most common expressions encountered in elementary algebra is
\[ (x + y)^2 = x^2 + 2xy + y^2. \]

You may also recall that
\[ (x + y)^3 = x^3 + 3x^2y + 3xy^2 + y^3 \]
\[ (x + y)^4 = x^4 + 4x^3y + 6x^2y^2 + 4xy^3 + y^4. \]
As the expressions above suggest, expanding the binomial \( x + y \) to the positive integer power \( n \) results in \( n + 1 \) terms, the first being \( x^n \) and the last \( y^6 \). The remaining \( n - 1 \) terms in \((x + y)^n\) are of the form \( x^{n-k}y^k \) where \( 1 \leq k \leq n - 1 \). The only question concerns the coefficient of each term \( x^{n-k}y^k \). Notice that the coefficients of the terms in the expansion of \((x + y)^n\) for \( n = 2, 3, 4 \) above are

\[
\begin{align*}
(x + y)^2 & = 1 \cdot 1 \quad \text{or} \quad \binom{2}{0} \binom{1}{1} \binom{2}{2} \\
(x + y)^3 & = 1 \cdot 3 \cdot 1 \quad \text{or} \quad \binom{3}{0} \binom{3}{1} \binom{3}{3} \\
(x + y)^4 & = 1 \cdot 4 \cdot 6 \cdot 1 \quad \text{or} \quad \binom{4}{0} \binom{4}{1} \binom{4}{2} \binom{4}{4}
\end{align*}
\]

all of which are rows in the Pascal triangle. That this represents the coefficients of all terms in the expansion of \((x + y)^n\) for every positive integer \( n \) is a consequence of one of the most famous theorems in combinatorics. We provide a combinatorial proof of this theorem.

**Theorem 13.28 (The Binomial Theorem)** For every positive integer \( n \),

\[
(x + y)^n = \binom{n}{0} x^n + \binom{n}{1} x^{n-1}y + \binom{n}{2} x^{n-2}y^2 + \cdots + \binom{n}{n-1} xy^n + \binom{n}{n} y^n.
\]

**Proof** Observe that

\[
(x + y)^n = (x + y)(x + y) \cdots (x + y)
\]

is the product of \( n \) binomials, each \( x + y \). To obtain a term in the expansion of \((x + y)^n\), either \( x \) or \( y \) is selected in each of these binomials \( x + y \) and these \( n \) terms are then multiplied. For example, if \( x \) is selected in each of the \( n \) binomials, we obtain \( x^n \). If \( y \) is selected in exactly one of the \( n \) binomials \( x + y \) and \( x \) in the remaining \( n - 1 \) binomials, we obtain \( x^{n-1}y \). Since there are \( n \) binomials in which \( y \) can be selected, the term containing \( x^{n-1}y \) in the expansion \((x + y)^n\) has the coefficient \( n \). More generally, to determine the coefficient of the term containing \( x^{n-k}y^k \) for \( 0 \leq k \leq n \) in the expansion of \((x + y)^n\), observe that there are \( \binom{n}{k} \) possible choices for \( k \) of the \( n \) binomials in which \( y \) is selected, with \( x \) selected in the remaining \( n - k \) binomials, giving us \( \binom{n}{k} x^{n-k}y^k \) for this term.

The following example illustrates the Binomial Theorem.

**Example 13.29** Expand \((x + y)^6\).

**Solution** By the Binomial Theorem,

\[
(x + y)^6 = \binom{6}{0} x^6 + \binom{6}{1} x^5y + \binom{6}{2} x^4y^2 + \binom{6}{3} x^3y^3 + \binom{6}{4} x^2y^4 + \binom{6}{5} xy^5 + \binom{6}{6} y^6 = x^6 + 6x^5y + 15x^4y^2 + 20x^3y^3 + 15x^2y^4 + 6xy^5 + y^6.
\]

In Example 13.29, observe that the coefficients in the expansion of \((x + y)^6\) are

\[1 \ 6 \ 15 \ 20 \ 15 \ 6 \ 1.\]
That is, the first coefficient is 1 and the coefficients increase until we reach the middle term 20 and then these coefficients are repeated in reverse order as they decrease back to 1. This is a consequence of the fact that

\[
{n \choose k} = {n \choose n - k},
\]

which we observed earlier. In the expansion of \((x + y)^5\), the coefficients are

\[
1 5 10 10 5 1
\]

and so there are two middle terms 10 in this case. In general, if \(n\) is an even integer, say \(n = 2k\), then there is exactly one middle term in the expansion of \((x + y)^n\), namely \({n \choose k}x^k y^{n-k}\); while if \(n\) is odd, say \(n = 2k + 1\), then there are two middle terms in the expansion of \((x + y)^n\), namely \({n \choose k}x^k y^{n-k}\) and \({n \choose k+1}x^{k+1} y^{n-k-1}\). (See Exercise 13.74.)

In the expansion of \((x + y)^n\) for a positive integer \(n\), we have seen that the first and last coefficients are 1, while the second and next-to-last coefficients are \({n \choose 1} = {n \choose n-1} = n\). That is, these four coefficients are easy to determine. Furthermore, the third coefficient is \({n \choose 2} = n(n-1)/2\), which, as noted earlier, is the product of \(n\) and \(n-1\) divided by 2. Therefore, the third coefficient from the end, namely \({n \choose n-2}\), is also \(n(n-1)/2\). These two coefficients can therefore usually be computed quite quickly as well. To compute other coefficients mentally, at least when \(n\) is not too large, the following theorem can be helpful.

**Theorem 13.30** For integers \(k\) and \(n\) with \(0 \leq k < n\),

\[
{n \choose k+1} = \frac{n}{k+1} \cdot \frac{n-k}{k+1} = \frac{n}{k+1} \cdot \frac{1}{(n-k-1)!}.
\]

**Proof** Observe that

\[
{n \choose k+1} = \frac{n!}{(n-k-1)!} \cdot \frac{1}{(n-k)!} \cdot \frac{1}{(k+1)!} = \frac{n!}{(k+1)! (n-k-1)!} = {n \choose k+1}.
\]

We now see how Theorem 13.30 and the Binomial Theorem can be used to expand \((x + y)^7\).

**Example 13.31** Expand \((x + y)^7\).

**Solution** We have seen that the expansion of \((x + y)^7\) begins with \(x^7 + 7x^6y + \binom{7}{2}x^5y^2\). Since \(\binom{7}{2} = 7 \cdot 6/2 = 21\), we have \(x^7 + 7x^6y + 21x^5y^2\). By Theorem 13.30, the next coefficient is obtained by multiplying the current coefficient 21 by the exponent 5 of \(x\) and dividing by 3 (since we are currently in the 3rd term), giving us 21 \cdot 5/3 = 35. We therefore have \(35x^4y^3\). Since this is a middle term, we can complete the expansion, arriving at

\[
(x + y)^7 = x^7 + 7x^6y + 21x^5y^2 + 35x^4y^3 + 35x^3y^4 + 21x^2y^5 + 7xy^6 + y^7.
\]

**Example 13.32** Expand \((x - y)^6\).
The Binomial Theorem

**Solution** By the Binomial Theorem,

\[(x - y)^6 = (x + (-y))^6 = x^6 + 6x^5(-y) + 15x^4(-y)^2 + 20x^3(-y)^3 +
\]
\[+ 15x^2(-y)^4 + 6x(-y)^5 + (-y)^6 = x^6 - 6x^5y + 15x^4y^2 - 20x^3y^3 + 15x^2y^4 - 6xy^5 + y^6. \]

\[\blacksquare\]

**Example 13.33** Expand \((2a + 3b)^5\).

**Solution** By the Binomial Theorem,

\[(2a + 3b)^5 = (2a)^5 + 5(2a)^4(3b) + 10(2a)^3(3b)^2 + 10(2a)^2(3b)^3 +
\]
\[+ 5(2a)(3b)^4 + (3b)^5 = 32a^5 + 5 \cdot 16 \cdot 3a^4b + 10 \cdot 8 \cdot 9a^3b^2 + 10 \cdot 4 \cdot 27a^2b^3 +
\]
\[+ 5 \cdot 2 \cdot 81ab^4 + 243b^5 = 32a^5 + 240a^4b + 720a^3b^2 + 1080a^2b^3 + 810ab^4 + 243b^5. \]

Letting \(x = y = 1\) in the Binomial Theorem yields a familiar fact (see Theorem 13.23).

**Example 13.34** Use the Binomial Theorem to show that

\[\binom{n}{0} + \binom{n}{1} + \binom{n}{2} + \cdots + \binom{n}{n} = 2^n.\]

**Solution** Letting \(x = y = 1\) in the Binomial Theorem, we have

\[(x + y)^n = (1 + 1)^n = 2^n = \binom{n}{0} + \binom{n}{1} + \binom{n}{2} + \cdots + \binom{n}{n}. \]

\[\blacksquare\]

Since \(\binom{n}{k}\) represents the number of \(k\)-element subsets in an \(n\)-element set, the left-hand expression in the statement of Example 13.34 represents the total number of subsets in an \(n\)-element set, which we know to be \(2^n\). We also saw this in Theorem 13.23.

Even in the case \(n = 2\), the Binomial Theorem can provide some interesting information.

**Example 13.35** For a positive integer \(n\), compute \((10n + 5)^2\).

**Solution** Observe that

\[(10n + 5)^2 = 100n^2 + 2 \cdot 5 \cdot 10n + 25 = 100n^2 + 100n + 25 = 100n(n + 1) + 25. \]

For example, if \(n = 8\), then Example 13.35 tells us that \((85)^2 = 100 \cdot 8 \cdot 9 + 25 = 7225\). That is, to compute \((85)^2\), we need only multiply 8 and 9, obtaining 72, and write 25 after this. Similarly, \((25)^2 = 625\) and \((95)^2 = 9025\).
SECTION 13.6 EXERCISES

13.63. (a) Expand \((3x - 5y)^4\).
   For parts (b)–(d), determine the coefficient of the power of \(x\) in the given expansion.
   (b) \(x^4\) in the expansion of the product \((2 + x + x^2)(1 - 2x)^6\).
   (c) \(x^{12}\) in the expansion of the product \((2x + 5)(3x + 4)^8\).
   (d) \(x^5\) in the expansion of \((x^3 - \frac{1}{2})^8\).

13.64. Prove that if the coefficient of \(x^0\) exists in the expansion of \((x^5 + \frac{3}{2})^n\), then \(7 \mid n\). What is the coefficient in this case?

13.65. For a real number \(r\), determine a formula for the sum \(\sum_{k=0}^{n} \binom{n}{k} r^k\).

13.66. Expand \((x^2 + 3xy + y^2)^4\) by first observing that \(x^2 + 2xy + y^2 = (x + y)^2\).

13.67. Compute \((1.1)^4\) without the aid of a calculator by first observing that \(1.1 = 1 + .1\).

13.68. For \(n \in \mathbb{N}\), let \(S\) be a set with \(n\) elements. Prove that the number of subsets of \(S\) having an even number of elements equals the number of subsets of \(S\) having an odd number of elements.

13.69. Recall from calculus that for a real number constant \(c\) and an integer \(n \geq 2\), the derivative of \((c + x)^n\) is \(\frac{d}{dx} (c + x)^n = n(c + x)^{n-1}\).
   (a) Use this result to prove that \(n2^{n-1} = \sum_{k=1}^{n} k\binom{n}{k}\) for each integer \(n \geq 2\).
   (b) Prove that \(\sum_{k=1}^{n} (-1)^{k-1} k\binom{n}{k} = 0\) for each integer \(n \geq 2\).
   (c) Prove that \(\binom{n}{1} + 3\binom{n}{2} + \cdots = 2\binom{n}{1} + 4\binom{n}{3} + \cdots\) for each integer \(n \geq 2\).
   (d) Determine a formula for the sum \(\sum_{k=0}^{n} (2k + 1)\binom{n}{k} = \binom{n}{0} + 3\binom{n}{1} + 5\binom{n}{2} + \cdots + (2n + 1)\binom{n}{n}\).

13.70. Observe that \(2 \mid \binom{2}{0}\), \(3 \mid \binom{3}{0}\), \(3 \mid \binom{3}{1}\), \(4 \mid \binom{4}{0}\) and \(5 \mid \binom{5}{0}\) for every integer \(k\) with \(1 \leq k \leq 4\). Prove for an integer \(p \geq 2\) that \(p \mid \binom{p}{k}\) for every integer \(k\) with \(1 \leq k \leq p - 1\) if and only if \(p\) is prime.

13.71. Prove that if \(p\) is a prime, then \((a + b)^p \equiv a^p + b^p \pmod{p}\). (See Exercise 13.70.)

13.72. Let \(r, m, n \in \mathbb{Z}\) where \(0 \leq r \leq m \leq n\). Prove that
   \[\sum_{k=0}^{r} \binom{m}{k}\binom{n}{r-k} = \binom{m+n}{r}\]
   by using
   (a) a combinatorial argument.
   (b) the Binomial Theorem and the identity \((1 + x)^m(1 + x)^n = (1 + x)^{m+n}\).

13.73. We saw in Exercise 13.72, for integers \(r, m\) and \(n\) with \(0 \leq r \leq m \leq n\), that
   \[\sum_{k=0}^{r} \binom{m}{k}\binom{n}{r-k} = \binom{m+n}{r}\] \hspace{1cm} (13.8)
   (a) Find a formula for \(\sum_{k=0}^{n} \binom{n}{k}\binom{n}{n-k}\) for every positive integer \(n\).
   (b) Prove for every positive integer \(n\) that \(\sum_{k=0}^{n} \binom{n}{k}^2 = \binom{2n}{n}\).
   (c) Use the identity in (13.8) to prove Pascal’s Identity: For integers \(r\) and \(n\) with \(1 \leq r \leq n\),
   \[\binom{n}{r-1} + \binom{n}{r} = \binom{n+1}{r}\].
13.7 Permutations and Combinations with Repetition

13.74. A finite sequence $a_1, a_2, \ldots, a_n$ of real numbers is unimodal if $a_1 < a_2 < \cdots < a_i = a_{i+1} = \cdots = a_j > a_{j+1} > \cdots > a_n$ for some integers $i$ and $j$ with $1 \leq i \leq j \leq n$. Prove the following.

(a) $\binom{n}{k} < \binom{n}{k+1}$ for $0 < k < (n - 1)/2$.
(b) $\binom{n}{k} > \binom{n}{k+1}$ for $k > (n - 1)/2$.
(c) $\binom{n}{k} = \binom{n}{k+1}$ if and only if $k = (n - 1)/2$.
(d) Use (a) and (b) to show that the sequence $\binom{n}{0}, \binom{n}{1}, \ldots, \binom{n}{n}$ is unimodal. In particular, show that if $n$ is odd and so $n = 2r + 1$ for some integer $r$, then

$$
\binom{n}{0} < \binom{n}{1} < \cdots < \binom{n}{r} = \binom{n}{r+1} > \cdots > \binom{n}{n};
$$

while if $n$ is even and so $n = 2s$ for some integer $s$, then

$$
\binom{n}{0} < \binom{n}{1} < \cdots < \binom{n}{s} > \binom{n}{s+1} > \cdots > \binom{n}{n}.
$$

(Consequently, $\binom{n}{r}$ are the largest terms in the sequence when $n = 2r + 1$ and $\binom{n}{r}$ is the largest term in the sequence when $n = 2s$.)

13.75. Let $n \in \mathbb{N}$ and let $a$ and $b$ be nonnegative integers such that $a < b$. Use Exercise 13.74 to prove that $\binom{n}{a} < \binom{n}{b}$ if and only if $a + b = n$.

13.76. Let $A$ and $B$ be disjoint sets with $|A| = m$ and $|B| = n$ and let $r$ be an integer with $0 \leq r < n \leq m$.

(a) Establish a formula for the number of $r$-permutations of $A \cup B$, expressing the formula in the notation of $r$-permutations as well as the notation of combinations.
(b) Establish a formula for the number of $r$-permutations of $A \cup B$, where an $r$-permutation is obtained by first selecting $k$ elements from $A$ and then selecting $r - k$ elements from $B$, where $0 \leq k \leq r$.
(c) What equality is obtained as a result of (a) and (b)?

13.7 PERMUTATIONS AND COMBINATIONS WITH REPETITION

One ordered list of the elements of the set $S = \{1, 2, \ldots, 9\}$ is the natural one: 1 2 3 4 5 6 7 8 9. This, of course, is an example of a permutation of $S$. We have seen that there is a total of $9! = 362,880$ permutations of $S$. Three other permutations of $S$ are

$$
1 2 3 4 5 6 7 9 8 \quad 1 2 3 4 5 7 8 6 9 \quad 1 2 3 4 5 9 8 7 6.
$$

In the first of these, only the last two terms are interchanged. Suppose, however, that we were to begin with the sequence 1 2 3 4 5 6 6 6 6. If the last two terms were to be interchanged in this sequence, then we would obtain exactly the same sequence of numbers. Therefore, the number of different ordered lists of these nine integers, only six of which are distinct, is not $9!$. In fact, this number is less than $9!$. Such ordered lists are called permutations with repetition. This suggests that when there is a repetition of some sort among $n$ elements, the number of distinct permutations is less than $n!$.

Suppose that we were to replace the last three terms of the sequence 1 2 3 4 5 6 6 6 6 by 6', 6'', 6''', arriving at 1 2 3 4 5 6 6' 6'' 6'''. Since all nine terms are now distinct, the number of permutations of these nine elements is $9!$. For each such permutation, there are $4!$ permutations of the elements of {6, 6', 6'', 6'''} that is, the number of distinct permutations of the integers in the list 1 2 3 4 5 6 6 6 6 is $9!/4!$. For the same reason, the number of distinct permutations of the terms in the list 1 2 3 3 3 6 6 6 6 is $9!/4!3!$ and the number of distinct permutations of the terms in the list 1 1 3 3 3 6 6 6 6 is

$$
\frac{9!}{4!3!2!} = 1260.
$$
This suggests the following theorem. Although a proof of the type described above could be given, we provide another method of proof.

**Theorem 13.36 (The Number of Distinct Permutations with Repetition)** Suppose that among \( n \) objects, there are exactly \( k \) distinct objects, namely \( n_1 \) of type 1, \( n_2 \) of type 2 and so on, up to \( n_k \) of type \( k \). Then the total number of distinct permutations of these \( n \) objects is

\[
\frac{n!}{n_1! n_2! \cdots n_k!}.
\]

**Proof**

Of the \( n \) positions for a permutation of these \( n \) objects, there are \( \binom{n}{n_1} \) possible locations for the \( n_1 \) elements of type 1. Of the remaining \( n - n_1 \) positions, there are \( \binom{n-n_1}{n_2} \) possible locations for the \( n_2 \) elements of type 2. Continuing in this manner, we see by the Multiplication Principle that the total number of distinct permutations of these \( n \) objects is

\[
\left( \frac{n}{n_1} \right) \left( \frac{n-n_1}{n_2} \right) \left( \frac{n-n_1-n_2}{n_3} \right) \cdots \left( \frac{n-n_1-n_2-\cdots-n_{k-1}}{n_k} \right) = \frac{n!}{n_1! (n-n_1)!} \cdot \frac{(n-n_1)!}{n_2! (n-n_1-n_2)!} \cdot \frac{(n-n_1-n_2)!}{n_3! (n-n_1-n_2-n_3)!} \cdots \frac{(n-n_1-n_2-\cdots-n_{k-1})!}{n_k! 0!} = \frac{n!}{n_1! n_2! \cdots n_k!}.
\]

**Example 13.37** Determine the number of distinct permutations of the elements in the list 1 1 1 2 2 2 3 3.

**Solution** By Theorem 13.36, this number is \( \frac{8!}{3!3!2!} = 560 \).

**Example 13.38** A mathematics professor has authored three books, namely one on calculus, one on linear algebra and one on mathematical proofs. He has four copies of the first book, two copies of the second book and one copy of the third book lined upon a shelf. In how many ways can these seven books be placed on the shelf?

**Solution** By Theorem 13.36, these books can placed on the shelf in \( \frac{7!}{4!2!1!} = 105 \) ways.

In all of the problems that we have encountered involving combinations, the elements involved have always been distinct. We now investigate the situation where repetition among the elements can occur. First, recall that the number of \( k \)-element subsets of an \( n \)-element set, \( 0 \leq k \leq n \), is

\[
C(n, k) = \binom{n}{k} = \frac{n!}{k! (n-k)!}.
\]

**Example 13.39** Suppose that three sets \( A \), \( B \) and \( C \) all have the property that they contain only duplicates of a particular element, say each element in \( A \) is \( a \), each element in \( B \) is \( b \), each element in \( C \) is \( c \) and the elements \( a \), \( b \) and \( c \) are distinct. Three elements are selected from \( A \cup B \cup C \). How many outcomes are possible?
solution One outcome is to have a selected for each element, which we denote by $aaa$ and another outcome occurs when one element $b$ is selected and two elements $c$ are selected, which we can denote by $bcc$. In fact, all possible outcomes are listed below:

$$aaa\,\ bbb\,\ ccc\,\ aab\,\ aac$$
$$abb\,\ bbc\,\ acc\,\ bcc\,\ abc.$$ 

Consequently, there are ten possible outcomes.

Sometimes, outcomes in which there is repetition of elements, as in Example 13.39, are expressed using set notation, that is,

$$\{a, a, a\}\quad\{b, b, b\}\quad\{c, c, c\}\quad\{a, a, b\}\quad\{a, a, c\}\quad\{a, b, b\}\quad\{b, b, c\}\quad\{a, c, c\}\quad\{b, c, c\}\quad\{a, b, c\}.$$ 

In this case, these are referred to as multiset.

The question in Example 13.39, however, asks for the number of possible outcomes when three elements are selected from $A \cup B \cup C$, not the actual outcomes themselves. It would not be practical to attempt to answer a question in this manner if there were a large number of different types of elements involved or a large number of elements selected. Problems of this nature can be looked at in another manner, however.

When an element of $A \cup B \cup C$ is selected, the element belongs to $A, B$ or $C$. So we can think of $A \cup B \cup C$ divided as follows.

$$A \mid B \mid C$$

The ten possible outcomes obtained in Example 13.39 can therefore be represented in the diagram below.

$$\begin{array}{ccc}
A & B & C \\
\text{aaa} & \bullet \bullet \bullet & | \mid \\
\text{bbb} & | \bullet \bullet \bullet & | \mid \\
\text{ccc} & | \mid | \bullet \bullet \bullet \\
\text{aab} & \bullet \bullet & | \mid \\
\text{aac} & \bullet \bullet & | \mid \\
\text{abb} & \bullet & | \bullet \bullet \mid \\
\text{bbc} & | \bullet \bullet \bullet & | \\
\text{acc} & | \mid \bullet \bullet \bullet \\
\text{bcc} & \bullet & | \bullet \bullet \bullet \\
\text{abc} & \bullet & | \bullet \bullet \mid \\
\end{array}$$

Observe that for each of the ten outcomes, there are five symbols, namely three symbols $\bullet$ used to denote the three elements selected and two symbols $|$ (vertical lines) used to denote how the three elements are divided among $A, B$ and $C$. So, in each case, we have five symbols

where two symbols are vertical separator lines and the remaining three symbols indicate how many elements belong to $A, B$ and $C$. Since there are $\binom{3}{3}$ places where the three symbols $\bullet$ can be located or, equivalently, $\binom{3}{2}$ places where the two separator lines $|$ can be located, the total number of outcomes is $\binom{3}{3} = \binom{3}{2} = 10$. 
This illustrates a general theorem concerning selections (or combinations) with repetition.

**Theorem 13.40** (The Number of Distinct Combinations with Repetition) Let \( A \) be a set containing \( t \) different kinds of elements, where there are at least \( s \) elements of each kind in \( A \). The number of different selections of \( s \) elements from \( A \) is

\[
\binom{s+t-1}{s}
\]

**Proof** Each selection of \( s \) elements from \( A \) corresponds to a sequence of \( s + t - 1 \) symbols

\[
\text{term 1} \quad \text{term 2} \quad \text{term 3} \quad \cdots \quad \text{term } s + t - 2 \quad \text{term } s + t - 1
\]

where \( s \) terms in the sequence correspond to the \( s \) elements selected from \( A \) and the remaining \( t - 1 \) terms in the sequence correspond to \( t - 1 \) separator lines, which are used to separate the \( s \) elements into the \( t \) different kinds. Since there are \( \binom{s+t-1}{s} \) locations in the sequence for the \( s \) elements, this is the number of different selections of \( s \) elements from \( A \).

**Example 13.41** A set \( A \) consists of 25 elements, 5 each of 5 different types. How many outcomes are possible when 4 elements are selected from \( A \)?

**Solution** Since there are \( t = 5 \) different types of elements in \( A \) and \( s = 4 \) elements are being selected from \( A \), it follows by Theorem 13.40 that the number of different outcomes is

\[
\binom{4+5-1}{4} = \binom{8}{4} = 70.
\]

Theorem 13.40 can also be used to determine the number of solutions of a certain type of equation.

**Example 13.42** Determine the number of nonnegative integer solutions of the equation \( x_1 + x_2 + x_3 = 6 \).

**Solution** Here we can use \( \ast \) to represent the integer 1. What we wish to do here is to distribute \( s = 6 \) symbols \( \ast \) and \( 3 - 1 = 2 \) vertical separator lines \( | \) for the values of the \( t = 3 \) variables. The number of ways to do this is

\[
\binom{6+3-1}{6} = \binom{8}{6} = \binom{8}{2} = 28
\]

and so there are 28 nonnegative integer solutions of this equation.

We next consider a related problem.

**Example 13.43** Determine the number of positive integer solutions of the equation \( x_1 + x_2 + x_3 = 6 \).

**Solution** Here we begin by assigning 1 to each of the three variables. This immediately guarantees that each of \( x_1, x_2 \) and \( x_3 \) will be a positive integer. It remains only to distribute the three
remaining 1s among the three variables and so \( s = 3 \). Since there are two separator lines \( | \) for the \( t = 3 \) variables, the number of such solutions is

\[
\binom{s + t - 1}{s} = \binom{3 + 3 - 1}{3} = \binom{5}{3} = \binom{5}{2} = 10.
\]

Actually, it is not that difficult to find all ten solutions in Example 13.43. They are

<table>
<thead>
<tr>
<th>( x_1 = 4, x_2 = x_3 = 1 )</th>
<th>( x_1 = 1, x_2 = 4, x_3 = 1 )</th>
<th>( x_1 = x_2 = 1, x_3 = 4 )</th>
</tr>
</thead>
<tbody>
<tr>
<td>( x_1 = 3, x_2 = 2, x_3 = 1 )</td>
<td>( x_1 = 3, x_2 = 1, x_3 = 2 )</td>
<td>( x_1 = 1, x_2 = 3, x_3 = 2 )</td>
</tr>
<tr>
<td>( x_1 = 2, x_2 = 3, x_3 = 1 )</td>
<td>( x_1 = 1, x_2 = 2, x_3 = 3 )</td>
<td>( x_1 = 2, x_2 = 1, x_3 = 3 )</td>
</tr>
<tr>
<td>( x_1 = x_2 = x_3 = 2 )</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

These solutions can be expressed more simply as follows:

\[
4 + 1 + 1 | 1 + 4 + 1 | 1 + 1 + 4 | 1 + 2 + 1 | 3 + 2 + 1 | 3 + 1 + 2
\]

\[
1 + 3 + 2 | 2 + 3 + 1 | 1 + 2 + 3 | 2 + 1 + 3 | 2 + 2 + 2.
\]

What these solutions provide are all ten ways to express the number 6 as an ordered sum of three positive integers. These are called the ordered partitions of 6 into three positive integers. This concept was described in Exercise 8.5. For example, all ordered partitions of 3 are \( 3, 1 + 2, 2 + 1 \) and \( 1 + 1 + 1 \). Thus, there are four ordered partitions of 3. This illustrates a theorem concerning this concept.

**Theorem 13.44** The number of ordered partitions of a positive integer \( n \) is \( 2^{n-1} \).

**Proof** First, observe that there is only one ordered partition of \( n \) as a sum of one positive integer \((n = n)\) and one ordered partition of \( n \) as a sum of \( n \) positive integers \((n = 1 + 1 + \cdots + 1, n \text{ terms})\) and that \( 1 = \binom{n-1}{0} = \binom{n-1}{1} \). Suppose then that we consider the number of ordered partitions of \( n \) as a sum of \( k \) positive integers for \( 2 \leq k \leq n - 1 \). Here we seek the number of positive integer solutions of the equation

\[
x_1 + x_2 + \cdots + x_k = n.
\]

We begin by assigning 1 to each of these \( k \) variables. It remains therefore to distribute \( n - k \) 1s among these \( k \) variables. This can be done by selecting \( n - k \) locations in a sequence with \((n - k) + (k - 1) = n - 1 \) terms, where \( n - k \) terms represent 1 and \( k - 1 \) terms represent separator lines. This number is \( \binom{n-1}{n-k} = \binom{n-1}{k-1} \). Hence, the total number of ordered partitions of \( n \) is

\[
\binom{n-1}{0} + \binom{n-1}{1} + \binom{n-1}{2} + \cdots + \binom{n-1}{n-2} + \binom{n-1}{n-1} = 2^{n-1}.
\]

We present one additional example dealing with combinations with repetition.

**Example 13.45** In how many ways can ten identical elements be divided among three sets \( S_1, S_2 \) and \( S_3 \) if \( |S_i| \geq i \) for \( i = 1, 2, 3 \)?

**Solution** We begin by assigning one element to \( S_1 \), two elements to \( S_2 \) and three elements to \( S_3 \). It remains therefore to determine the number of ways that the remaining \( 10 - 6 = 4 \)
elements can be divided among these three sets. Applying Theorem 13.44 with \( s = 4 \) and \( t = 3 \), we see that the number of ways to do this is
\[
\binom{s + t - 1}{s} = \binom{4 + 3 - 1}{4} = \binom{6}{4} = \binom{6}{2} = 15.
\]

**SECTION 13.7 EXERCISES**

13.77. For the list \( s, s, t, t, t, u, u, i, o, n, b \) of 13 letters, determine
(a) the number of permutations of these letters.
(b) the number of permutations of these letters in which the three letters \( s \) occupy positions 1, 4 and 10.
(c) the number of 12-permutations of these letters.

13.78. Determine the number of 4-permutations of the letters in the word CHATTER.

13.79. How many positive integers each digit of which is 8 or 6 contain exactly five 8s and at most three 6s?

13.80. Twelve donuts are to be chosen from 15 varieties of donuts, each in good supply.
   (a) In how many ways can this be done?
   (b) In how many ways can this be done if all twelve donuts are selected from only eight of the 15 varieties and at least one donut of each type is selected?

13.81. Let \( m, n \in \mathbb{Z} \). Determine the number of nonnegative integer solutions of the equation
\[ x_1 + x_2 + \cdots + x_n = m. \]

13.82. The \( m \) employees of an organization are to be assigned to \( n \) different offices (numbered 1, 2, \ldots, \( n \)) where \( m \geq n \). Some offices may be left empty and each office is large enough to accommodate all \( m \) employees.
   (a) In how many ways can this be done?
   (b) In how many ways can this be done if we are only concerned with the number of employees assigned to each office?
   (c) If \( m = 10 \) and \( n = 5 \), determine the number of ways of assigning offices to the ten employees if each office is to have an equal number (2) of employees.

13.83. In how many ways can three gold coins and ten silver coins be placed in four boxes of different colors?

13.84. Let \( S = \{2, 3, 5, 7\} \) and \( M = \{n \in \mathbb{N} : n = q_1q_2q_3q_4q_5q_6 \text{ where } q_i \in S \text{ for } 1 \leq i \leq 6\} \).
   (a) Determine \( |M| \).
   (b) Determine the number of elements of \( M \) that are divisible by at least one of 2, 3 and 7.
   (c) How many elements of \( M \) have 0 as their last digit?

13.85. Expand the following.
   (a) \((x + y + z)^2\).
   (b) \((x + y + z)^3\).

13.86. What is the coefficient of \( x^2y^2z^2 \) in the expansion of \((x + y + z)^6\)?

13.87. For an integer \( n \geq 2 \), let \( S = \{(i, j, k) : i, j, k \in \mathbb{N} \cup \{0\} \text{ and } i + j + k = n\} \).
   (a) Determine \( |S| \).
   (b) For \((i, j, k) \in S\), determine the coefficient of \( x^iy^jz^k \) in the expansion of \((x + y + z)^n\).
   (c) How many terms are there in the expansion of \((x + y + z)^n\)?
   (d) State the "trinomial theorem."
   (e) What is the sum of the coefficients in the expansion of \((x + y + z)^n\)?
13.88. Let \( f : A \rightarrow B \) where \( A = \{1, 2, \ldots, m\} \) and \( B = \{1, 2, \ldots, n\} \). How many different possibilities are there for the sequence \(|f^{-1}(\{1\})|, |f^{-1}(\{2\})|, \ldots, |f^{-1}(\{n\})|\)?

13.89. Let \( m, n \in \mathbb{N} \) where \( m > \binom{n+1}{2} = \sum_{i=1}^{n} i \). Determine the number of integer solutions of the equation \( x_1 + x_2 + \cdots + x_n = m \) for which \( x_i \geq i \) for each \( 1 \leq i \leq n \).

13.90. Determine the number of integer solutions of the equation \( x_1 + x_2 + x_3 + x_4 = 20 \) where \( 1 \leq x_1 \leq 4 \) and \( x_i \geq 0 \) for \( i = 2, 3, 4 \).

13.91. (a) Which pairs \( a, b \) of integers can be removed from the sequence \( 1, 2, 3, 4, 5, 6 \) where \( a < b \) and \( b \neq a + 1 \)?

(b) In how many ways can six integers be removed from the sequence \( 1, 2, 3, \ldots, 14 \) if no two of the six integers are consecutive?

### Chapter 13 Supplemental Exercises

13.92. Determine the number of \( m \)-digit positive integers that do not contain the digit 1.

(Thus, the first digit is neither 0 nor 1.)

13.93. Determine the number of ways to express 100,000 as an ordered product of two positive integers. For example, the two products 100 \( \cdot \) 1000 and 1000 \( \cdot \) 100 are different ordered products.

13.94. (a) Let \( p_1, p_2, p_3, p_4 \) be distinct primes and let \( a_1, a_2, a_3, a_4 \) be positive integers. Determine the number of distinct positive divisors of \( n = p_1^{a_1} p_2^{a_2} p_3^{a_3} p_4^{a_4} \).

(b) Prove that the integer \( n \) in (a) has an odd number of positive divisors if and only if \( n \) is a perfect square.

13.95. Let \( S = \{1, 3, 4, 5, 7, 9\} \).

(a) How many 4-digit positive integers are there where each digit belongs to \( S \)?

(b) How many of the numbers in (a) are divisible by 5?

13.96. Let \( P = \{2, 3, 5, 7\}, M = \{n \in \mathbb{N} : n \text{ is a product of 10 elements in } P\} \) and \( A_k = \{a \in M : 3^k \mid a \text{ but } 3^{k+1} \nmid a\} \) for \( k \in S = \{0, 1, \ldots, 10\} \).

(a) Determine \( |A_k| \) for each \( k \in S \)

(b) Show that the sets \( A_0, A_1, \ldots, A_k \) are pairwise disjoint.

(c) Determine the number of integers in \( M \) that are not divisible by \( 3^5 \).

13.97. Determine the number of surjective functions from the set \( A = \{1, 2, \ldots, 10\} \) to the set \( B = \{1, 2, 3, 4\} \).

13.98. How many positive integers less than 850 have no repeated digits?

13.99. Let \( A = \{1, 2, \ldots, 25\}, A_1 = \{1, 2, \ldots, 5\}, A_2 = \{6, 7, \ldots, 15\} \) and \( A_3 = \{16, 17, \ldots, 25\} \). A function \( f : A \rightarrow A \) satisfies \( f(A_i) \subseteq A_i \) for each \( i = 1, 2, 3 \).

(a) How many such functions are there?

(b) How many such functions are injective?

(c) How many such functions are there such that \( f(A_i) \) consists of exactly one element for each \( i = 1, 2, 3 \)?

13.100. Let \( n \in \mathbb{N} \). Prove that if \( a_1, a_2, \ldots, a_{n+1} \) are \( n + 1 \) distinct integers, then there exist two among them whose difference is divisible by \( n \).
13.101. Let \( a, n \in \mathbb{N} \). Prove that if \( n + 1 \) elements are selected from the set 
\( S = \{ a + 1, a + 2, \ldots, a + 2n \} \), then there exist two elements of \( S \) that differ by \( n \).

13.102. Prove for any nine integers in the set \( S = \{ 1, 2, \ldots, 19 \} \) that there exist three pairs among them having the same positive difference.

13.103. In preparation for a forthcoming concert, a violinist plans to practice one or more blocks of one-hour sessions each day for two weeks for a total of 20 hours. Show that during some set of consecutive days, the violinist will have practiced exactly seven hours.

13.104. Let \( k, r \) and \( n \) be integers with \( 0 \leq k \leq r \leq n \). Use a combinatorial proof to show that 
\[
\binom{n}{r} = \sum_{i=0}^{k} \binom{k}{i} \binom{n-k}{r-i}.
\]

13.105. Let \( a_1, a_2, \ldots, a_{56} \) be integers with \( 1 \leq a_1 < a_2 < \cdots < a_{56} \leq 100 \). Prove for each integer \( k \) with \( 1 \leq k \leq 11 \) that there exist two terms in the sequence that differ by \( k \).

13.106. Let \( n \in \mathbb{N} \). Prove that if more than half of the subsets of an \( n \)-element set are chosen, then there are two among them such that one is a subset of the other.

13.107. A derangement of a set \( S = \{ 1, 2, \ldots, n \} \) is a permutation \( f \) of \( S \) such that \( f(k) \neq k \) for each \( k \in S \). The number of derangements of \( S \) is denoted by \( D(n) \). Therefore, \( D(1) = 0, D(2) = 1 \) and \( D(3) = 2 \).

(a) What are the derangements of \( \{ 1, 2, 3, 4 \} \)?
(b) Use the Principle of Inclusion-Exclusion to determine \( D(4) \).
(c) Use a combinatorial argument to prove that for \( n \geq 3 \), \( D(n) \) satisfies the recurrence relation \( D(n) = (n-1)(D(n-1) + D(n-2)) \). [Hint: If \( f : S \to S \) is a derangement of \( S \), then \( f(1) = a \) for some \( a \neq 1 \) and either \( f(a) = 1 \) or \( f(a) \neq 1 \).]

13.108. Recall from calculus that for a positive integer \( n \), 
\[
\int (1 + x)^n \, dx = \frac{(1 + x)^{n+1}}{n+1} + C
\]
and therefore, 
\[
\int_0^1 (1 + x)^n \, dx = \frac{2^{n+1} - 1}{n+1}.
\]
Prove that 
\[
\sum_{k=0}^{n} \frac{1}{k+1} \binom{n}{k} = \frac{2^{n+1} - 1}{n+1}
\]
for every positive integer \( n \).

13.109. Let \( S = \{ 1, 2, \ldots, 3n \} \) where \( n \in \mathbb{N} \).
(a) Show for any \( (2n + 1) \)-element subset \( T \) of \( S \) that there exist \( a, b \in T \) such that \( a = 3s \) and \( b = 3t \) where \( r < s \) and \( 3 \nmid t \).
(b) Show that the statement in (a) is false for \( (2n) \)-element subsets of \( S \).
14

Proofs in Calculus

Your introduction to calculus most certainly included a study of limits -- both limits of sequences (including infinite series) and limits of functions (including continuity and differentiability). While we learned methods for computing limits in these areas, the methods presented were most likely based on facts that were not carefully verified. In this chapter, some of the proofs of fundamental results from calculus will be presented. The proofs that occur in calculus are considerably different from any of those we have seen thus far. The functions encountered in calculus are real-valued functions defined on sets of real numbers. That is, each function that we study in calculus is of the type \( f : X \rightarrow \mathbb{R} \), where \( X \subseteq \mathbb{R} \). In the study of limits, we are often interested in such functions having the property that either (1) \( X = \mathbb{N} \) and increasing values in the domain \( \mathbb{N} \) result in functional values approaching some real number \( L \) or (2) the function is defined for all real numbers near some specified real number \( a \) and domain values approaching \( a \) result in functional values approaching some real number \( L \). We begin with (1), where \( X = \mathbb{N} \).

14.1 LIMITS OF SEQUENCES

A sequence (of real numbers) is a real-valued function defined on the set of natural numbers; that is, a sequence is a function \( f : \mathbb{N} \rightarrow \mathbb{R} \). If \( f(n) = a_n \) for each \( n \in \mathbb{N} \), then \( f = \{(1, a_1), (2, a_2), (3, a_3), \ldots \} \). Since only the numbers \( a_1, a_2, a_3, \ldots \) are relevant in \( f \), this sequence is often denoted only by \( a_1, a_2, a_3, \ldots \) or by \( \{a_n\} \). The numbers \( a_1, a_2, a_3, \) etc. are called the terms of the sequence \( \{a_n\} \), with \( a_1 \) being the first term, \( a_2 \) the second term, etc. Thus, \( a_n \) is the \( n \)th term of the sequence. Hence, \( \left\{ \frac{1}{n} \right\} \) is the sequence \( 1, 1/2, 1/3, \ldots \); while \( \left\{ \frac{n}{2n+1} \right\} \) is the sequence \( 1/3, 2/5, 3/7, \ldots \). In these two examples, the \( n \)th term of a sequence is given and, from this, we can easily find the first few terms and, in fact, any particular term. On the other hand, finding the \( n \)th term of a sequence whose first few terms are given can be challenging. For example, the \( n \)th term of the sequence

\[
\frac{1}{2} \cdot \frac{1}{4} \cdot \frac{1}{6} \cdot \ldots
\]
366 Chapter 14 Proofs in Calculus

is \( \frac{1}{2^n} \); the \( n \)th term of the sequence

\[
1 + \frac{1}{2}, 1 + \frac{1}{4}, 1 + \frac{1}{8}, \ldots
\]
is \( 1 + 1/2^n \); the \( n \)th term of the sequence

\[
1, \frac{3}{5}, 1, \frac{5}{11}, 1, \frac{7}{17}, \ldots
\]
is \((n + 1)/(3n - 1)\); the \( n \)th term of the sequence

\[
1, -1, 1, -1, 1, -1, \ldots
\]
is \((-1)^{n+1}\); while the \( n \)th term of the sequence \( 1, 4, 9, 16, \ldots \) is \( n^2 \).

For the sequence \( \{\frac{1}{n}\} \), the larger the integer \( n \), the closer \( 1/n \) is to 0; and for the sequence \( \{\frac{n}{2n + 1}\} \), the larger the integer \( n \), the closer \( n/(2n + 1) \) is to 1/2. On the other hand, for the sequence \( \{n^2\} \), as the integer \( n \) become larger, \( n^2 \) becomes increasingly large and does not approach any real number.

When we discuss how close two numbers are to each other, we are actually considering the distance between them. We saw in Chapter 9 that the distance between two real numbers \( a \) and \( b \) is defined as \( |a - b| = |b - a| \). Recall that the absolute value of a real number \( x \) is

\[
|x| = \begin{cases} 
  x & \text{if } x \geq 0 \\
  -x & \text{if } x < 0.
\end{cases}
\]

Hence, the distance between \( a = 3 \) and \( b = 5 \) is \(|3 - 5| = |5 - 3| = 2\), while the distance between 0 and \( 1/n \), where \( n \in \mathbb{N} \), is

\[
\left| 0 - \frac{1}{n} \right| = \left| \frac{1}{n} - 0 \right| = \frac{1}{n}.
\]

For a fixed positive real number \( r \), the inequality \(|x| < r \) is equivalent to the inequalities \(-r < x < r\). Hence, \(|x| < 3\) is equivalent to \(-3 < x < 3\), while \(|x - 2| < 4\) is equivalent to \(-4 < x - 2 < 4\). Adding 2 throughout these inequalities, we obtain \(-4 + 2 < (x - 2) + 2 < 4 + 2\) and so, \(-2 < x < 6\). We have seen in Exercise 4.30 and Theorem 4.17 that for real numbers \( x \) and \( y \),

\[
|x| = |x||y| \quad \text{and} \quad |x + y| \leq |x| + |y|.
\]

Both of these properties are useful throughout calculus.

We mentioned that for some sequences \( \{a_n\} \), there is a real number \( L \) (or at least there appears to be a real number \( L \)) such that the larger the integer \( n \) becomes, the closer \( a_n \) is to \( L \). We have now arrived at an important and fundamental idea in the study of sequences and are prepared to introduce a concept that describes this situation.

A sequence \( \{a_n\} \) of real numbers is said to converge to a real number \( L \) if the larger the integer \( n \), the closer \( a_n \) is to \( L \). Since the words “larger” and “closer” are vague and consequently are open to interpretation, we need to make these words considerably more precise.

What we want to say then is that we can make \( a_n \) as close to \( L \) as we wish (that is, we can make \(|a_n - L| \) as small as we wish) provided that \( n \) is large enough. Let \( \epsilon \) (the Greek letter epsilon) denote how small we want \(|a_n - L| \) to be; that is, we want \(|a_n - L| < \epsilon \) by choosing \( n \) large enough. This is equivalent to \(-\epsilon < a_n - L < \epsilon \), that is,
Let \( L - \epsilon < a_n < L + \epsilon \). Hence, we require that \( a_n \) be a number in the open interval \((L - \epsilon, L + \epsilon)\) when \( n \) is large enough. Now we need to know what we mean by “large enough.” What we mean by this is that there is some positive integer \( N \) such that if \( n \) is any integer greater than \( N \), then \( a_n \in (L - \epsilon, L + \epsilon) \). If such a positive integer \( N \) can be found for every positive number \( \epsilon \), regardless of how small \( \epsilon \) might be, then we say that \( \{a_n\} \) converges to \( L \). This is illustrated in Figure 14.1.

Formally then, a sequence \( \{a_n\} \) of real numbers is said to converge to the real number \( L \) if for every real number \( \epsilon > 0 \), there exists a positive integer \( N \) such that if \( n \) is an integer with \( n > N \), then \( |a_n - L| < \epsilon \). As we indicated, the number \( \epsilon \) is a measure of how close the terms \( a_n \) are required to be to the number \( L \) and \( N \) indicates a position in the sequence beyond which the required condition is satisfied. If a sequence \( \{a_n\} \) converges to \( L \), then \( \{a_n\} \) is a convergent sequence and \( L \) is referred to as the limit of \( \{a_n\} \) and we write \( \lim_{n \to \infty} a_n = L \). If a sequence does not converge, it is said to diverge. Consequently, if a sequence \( \{a_n\} \) diverges, then there is no real number \( L \) such that \( \lim_{n \to \infty} a_n = L \).

Before looking at a few examples, let’s recall a concept that’s been encountered before. For a real number \( x \), the ceiling \([x]\) of \( x \) is the smallest integer greater than or equal to \( x \). Consequently, \([8/3] = 3\), \(\sqrt{2} \approx 1.414 \approx 1.6\), \(\left[-1.6\right] = -1\) and \([5] = 5\). By the definition of \([x]\), it follows that if \( x \) is an integer, then \([x] = x\), while if \( x \) is not an integer, then \([x] > x\). In particular, if \( n \) is an integer such that \( n > [x]\), then \( n > x \) as well.

We now show how the definition of convergent sequence is used to prove that a sequence converges to some number.

**Result to Prove**  
The sequence \( \left\{\frac{1}{n}\right\} \) converges to 0.

**Proof Strategy**  
Here we are required to show, for a given real number \( \epsilon > 0 \), that there is a positive integer \( N \) such that if \( n > N \), then \( \left|\frac{1}{n} - 0\right| = \frac{1}{n} < \epsilon \). The inequality \( \frac{1}{n} < \epsilon \) is equivalent to \( n > 1/\epsilon \). Hence, if we let \( N = \lceil 1/\epsilon \rceil \) and take \( n \) to be an integer greater than \( N \), then \( n > \frac{1}{\epsilon} \). We can now present a formal proof.
368 Chapter 14 Proofs in Calculus

Result 14.1 The sequence \( \left\{ \frac{1}{n} \right\} \) converges to 0.

Proof Let \( \epsilon > 0 \). Choose \( N = \lceil 1/\epsilon \rceil \) and let \( n \) be any integer such that \( n > N \). Thus, \( n > 1/\epsilon \) and so \( \left| \frac{1}{n} - 0 \right| = \frac{1}{n} < \epsilon \).

PROOF ANALYSIS Although the proof of Result 14.1 is quite short, the real work in constructing the proof occurred in the proof strategy (our “scratch paper” work) that preceded the proof, but which is not part of the proof. This explains why we chose \( N \) as we did and why this choice of \( N \) was successful. In the proof of Result 14.1, we chose \( N = \lceil 1/\epsilon \rceil \) and showed that with this value of \( N \), every integer \( n \) with \( n > N \) yields \( \left| \frac{1}{n} - 0 \right| < \epsilon \), which, of course, was our goal. There is nothing unique about this choice of \( N \), however. Indeed, we could have chosen \( N \) to be any integer greater than \( \lceil 1/\epsilon \rceil \) or, equivalently, any integer greater than \( 1/\epsilon \) and reached the desired conclusion as well. We could not, however, choose \( N \) to be an integer smaller than \( \lceil 1/\epsilon \rceil \). We cannot in general choose \( N = 1/\epsilon \) since there is no guarantee that \( N \) is an integer.

We now consider another illustration of a convergent sequence.

Result to Prove The sequence \( \left\{ 3 + \frac{2}{n^2} \right\} \) converges to 3.

PROOF STRATEGY Here we are required to show, for a given \( \epsilon > 0 \), that there exists a positive integer \( N \) such that if \( n > N \), then

\[
\left| \left( 3 + \frac{2}{n^2} \right) - 3 \right| = \left| \frac{2}{n^2} \right| = \frac{2}{n^2} < \epsilon.
\]

The inequality \( \frac{2}{n^2} < \epsilon \) is equivalent to \( \frac{n^2}{2} > \frac{1}{\epsilon} \) and \( n > \sqrt{2}/\epsilon \). Therefore, if we let \( N = \lceil \sqrt{2}/\epsilon \rceil \) and choose \( n \) to be an integer greater than \( N \), then \( n > \sqrt{2}/\epsilon \). We can now give a proof.

Result 14.2 The sequence \( \left\{ 3 + \frac{2}{n^2} \right\} \) converges to 3.

Proof Let \( \epsilon > 0 \). Choose \( N = \lceil \sqrt{2}/\epsilon \rceil \) and let \( n \) be any integer such that \( n > N \). Thus, \( n > \sqrt{2}/\epsilon \) and \( n^2 > 2/\epsilon \). So \( \frac{1}{n^2} < \frac{\epsilon}{2} \) and \( \frac{2}{n^2} < \epsilon \). Therefore,

\[
\left| \left( 3 + \frac{2}{n^2} \right) - 3 \right| = \left| \frac{2}{n^2} \right| = \frac{2}{n^2} < \epsilon.
\]

We now consider a somewhat more complicated example.
Result to Prove  The sequence $\left\{ \frac{n}{2n + 1} \right\}$ converges to $\frac{1}{2}$.

PROOF STRATEGY  Observe that

$$\left| \frac{n}{2n + 1} - \frac{1}{2} \right| = \left| \frac{2n - 2n - 1}{2(2n + 1)} \right| = \left| -\frac{1}{4n + 2} \right| = \frac{1}{4n + 2}.$$ 

The inequality $\frac{1}{4n + 2} < \epsilon$ is equivalent to $4n + 2 > \frac{1}{\epsilon}$, which, in turn, is equivalent to $n > \frac{1}{4\epsilon} - \frac{1}{2}$. It may appear that the proper choice for $N$ is $\lceil \frac{1}{4\epsilon} - \frac{1}{2} \rceil$; but if $\epsilon \geq \frac{1}{2}$, then $N = 0$, which is not acceptable since $N$ is required to be a positive integer. However, notice that $\frac{1}{4\epsilon} > \frac{1}{4\epsilon} - \frac{1}{2}$. So if $n > \frac{1}{4\epsilon}$, then $n > \frac{1}{4\epsilon} - \frac{1}{2}$ as well. Hence, if we choose $N = \lceil \frac{1}{4\epsilon} \rceil$, then we can obtain the desired inequality. ♦

Result 14.3  The sequence $\left\{ \frac{n}{2n + 1} \right\}$ converges to $\frac{1}{2}$.

Proof  Let $\epsilon > 0$ be given. Choose $N = \lceil \frac{1}{4\epsilon} \rceil$ and let $n > N$. Then $n > \frac{1}{4\epsilon} > \frac{1}{4\epsilon} - \frac{1}{2}$ and so $4n > 1\epsilon - 2$ and $4n + 2 > 1/\epsilon$. Hence, $\frac{1}{4n + 2} < \epsilon$. Thus

$$\left| \frac{n}{2n + 1} - \frac{1}{2} \right| = \left| \frac{2n - 2n - 1}{2(2n + 1)} \right| = \left| -\frac{1}{4n + 2} \right| = \frac{1}{4n + 2} < \epsilon.$$ 

Again, the choice made for $N$ in the proof of Result 14.3 is not unique. We could choose $N$ to be any integer greater than $\frac{1}{4\epsilon}$.

We mentioned that a sequence $\{a_n\}$ is said to diverge if it does not converge. To prove that a sequence $\{a_n\}$ diverges, a proof by contradiction would be anticipated. We would begin such a proof by assuming, to the contrary, that $\{a_n\}$ converges, say to some real number $L$. We know that for every $\epsilon > 0$, there is a positive integer $N$ such that if $n > N$, then $|a_n - L| < \epsilon$. If we could show even for one choice of $\epsilon > 0$ that no such positive integer $N$ exists, then we would have produced a contradiction and the desired result would be proved. Let’s see how this works in two examples.

Result to Prove  The sequence $\left\{ (-1)^{n+1} \right\}$ is divergent.

PROOF STRATEGY  First, let’s be certain we know what the sequence $\left\{ (-1)^{n+1} \right\}$ is. It could also be written as $1, -1, 1, -1, \ldots$. Initially, one might think that this sequence converges either to 1 or to $-1$. However, such is not the case. In a proof by contradiction, we begin by assuming that $\left\{ (-1)^{n+1} \right\}$ converges, to the limit $L$ say. Our goal is to show that there is some value of $\epsilon > 0$ for which there is no positive integer $N$ that satisfies the requirement. We choose $\epsilon = 1$. According to the definition of what it means for $\left\{ (-1)^{n+1} \right\}$ to converge
to \( L \), there must exist a positive integer \( N \) such that if \( n \) is an integer with \( n > N \), then 
\[
|(-1)^{n+1} - L| < \epsilon = 1.
\]
Let \( k \) be an odd integer such that \( k > N \). Then
\[
|(-1)^k - L| = |1 - L| = |L - 1| < 1.
\]
Therefore, \(-1 < L - 1 < 1\) and \( 0 < L < 2 \). Now let \( \ell \) be an even integer such that \( \ell > N \). Then
\[
|(-1)^{\ell+1} - L| = |-1 - L| = |L + 1| < 1.
\]
Thus, \(-1 < L + 1 < 1\) and \(-2 < L < 0 \). So, \( L < 0 < L\), which, of course, is impossible. We now repeat what we have just said in a formal proof.

\[\Box\]

Result 14.4 The sequence \( \{(-1)^{n+1}\} \) is divergent.

**Proof** Assume, to the contrary, that the sequence \( \{(-1)^{n+1}\} \) converges. Then 
\[
\lim_{n \to \infty} (-1)^{n+1} = L \text{ for some real number } L.
\]
Let \( \epsilon = 1 \). Then there exists a positive integer \( N \) such that if \( n > N \), then
\[
|(-1)^{n+1} - L| < \epsilon = 1.
\]
Let \( k \) be an odd integer such that \( k > N \). Then
\[
|(-1)^k - L| = |1 - L| = |L - 1| < 1.
\]
Therefore, \(-1 < L - 1 < 1\) and \( 0 < L < 2 \). Next, let \( \ell \) be an even integer such that \( \ell > N \). Then
\[
|(-1)^{\ell+1} - L| = |-1 - L| = |L + 1| < 1.
\]
So \(-1 < L + 1 < 1\) and \(-2 < L < 0 \). Therefore, \( L < 0 < L\), which is a contradiction.

**Proof Analysis** One question that now occurs is how we knew to choose \( \epsilon = 1 \). If \( \epsilon \) denotes an arbitrary positive integer, then both inequalities \(|L - 1| < \epsilon\) and \(|L + 1| < \epsilon\) must be satisfied, but these result in the inequalities
\[
1 - \epsilon < L < 1 + \epsilon \text{ and } -1 - \epsilon < L < -1 + \epsilon.
\]
In particular, \(1 - \epsilon < L < -1 + \epsilon\) and so \(1 - \epsilon < -1 + \epsilon\). This is only possible if \(2\epsilon > 2\) or \(\epsilon > 1\). Hence, if we choose \( \epsilon \) to be any number such that \(0 < \epsilon \leq 1\), a contradiction will be produced. We decided to choose \( \epsilon = 1 \).

\[\Box\]

Result to Prove The sequence \( \{(−1)^{n+1}\frac{n}{n+1}\} \) is divergent.

**Proof Strategy** As expected, we will attempt a proof by contradiction and assume that \( \{(−1)^{n+1}\frac{n}{n+1}\} \) is a convergent sequence, with limit \( L \) say. For \( \epsilon > 0 \), there is a positive integer \( N \) then such that
\[
|(-1)^{n+1}\frac{n}{n+1} - L| < \epsilon
\]
for each integer \( n \) such that \( n > N \). There are some useful observations.

First, if \( n > N \) and \( n \) is odd, then
\[
|\frac{n}{n+1} - L| < \epsilon \text{ and so } -\epsilon < \frac{n}{n+1} - L < \epsilon.
\]
Hence,\[L - \epsilon < \frac{n}{n + 1} < L + \epsilon.\]

Second, if \(n > N\) and \(n\) is even, then
\[
\left|\frac{n}{n + 1} - L\right| < \epsilon \quad \text{and so} \quad -\epsilon < -\frac{n}{n + 1} - L < \epsilon.
\]

Hence,\[L - \epsilon < -\frac{n}{n + 1} < L + \epsilon.\]

Also, since \(n > 1\), we have \(n + n > n + 1\) and so \(2n > n + 1\). Hence, \(\frac{n}{n + 1} > \frac{1}{2}\).

Depending on whether \(L = 0\), \(L > 0\) or \(L < 0\), we are faced with the decision as to how to choose \(\epsilon\) in each case to produce a contradiction. ♦

**Result 14.5** The sequence \(\{(-1)^{n+1} \cdot \frac{n}{n+1}\}\) is divergent.

**Proof** Assume, to the contrary, that \(\{(-1)^{n+1} \cdot \frac{n}{n+1}\}\) converges. Then \(\lim_{n \to \infty} (-1)^{n+1} \cdot \frac{n}{n+1} = L\) for some real number \(L\). We consider three cases, depending on whether \(L = 0\), \(L > 0\) or \(L < 0\).

**Case 1.** \(L = 0\). Let \(\epsilon = \frac{1}{2}\). Then there exists a positive integer \(N\) such that if \(n > N\),
then \(\left|(-1)^{n+1} \cdot \frac{n}{n+1} - 0\right| < \frac{1}{2}\) or \(\frac{n}{n + 1} < \frac{1}{2}\). Then \(2n < n + 1\) and so \(n < 1\), which is a contradiction.

**Case 2.** \(L > 0\). Let \(\epsilon = \frac{L}{2}\). Then there exists a positive integer \(N\) such that if \(n > N\), then \(\left|(-1)^{n+1} \cdot \frac{n}{n+1} - L\right| < \frac{L}{2}\). Let \(n\) be an even integer such that \(n > N\). Then
\[
-\frac{L}{2} < -\frac{n}{n + 1} - L < \frac{L}{2}.
\]

Hence, \(\frac{L}{2} < -\frac{n}{n + 1} < \frac{3L}{2}\), which is a contradiction.

**Case 3.** \(L < 0\). Let \(\epsilon = -\frac{L}{2}\). Then there exists a positive integer \(N\) such that if \(n > N\),
then \(\left|(-1)^{n+1} \cdot \frac{n}{n+1} - L\right| < -\frac{L}{2}\). Let \(n\) be an odd integer such that \(n > N\). Then
\[
\frac{L}{2} < \frac{n}{n + 1} - L < -\frac{L}{2},
\]
and so \(\frac{3L}{2} < \frac{n}{n + 1} < \frac{L}{2}\). This is a contradiction. ■
Chapter 14  Proofs in Calculus

A sequence \( \{a_n\} \) may diverge because as \( n \) becomes larger, \( a_n \) becomes larger and eventually exceeds any given real number. If a sequence has this property, then \( \{a_n\} \) is said to diverge to infinity. More formally, a sequence \( \{a_n\} \) diverges to infinity, written \( \lim_{n \to \infty} a_n = \infty \), if for every positive number \( M \), there exists a positive integer \( N \) such that if \( n \) is an integer such that \( n > N \), then \( a_n > M \). The sequence \( \{-1\}^{n+1} \) encountered in Result 14.4, although divergent, does not diverge to infinity. However, the sequence \( \{n^2 + \frac{1}{n}\} \) does diverge to infinity.

Result to Prove \[ \lim_{n \to \infty} \left( n^2 + \frac{1}{n} \right) = \infty. \]

PROOF STRATEGY For a given positive number \( M \), we are required to show the existence of a positive integer \( N \) such that if \( n > N \), then \( n^2 + \frac{1}{n} > M \). Notice that if \( n^2 > M \), then \( n^2 + \frac{1}{n} > n^2 > M \). Since \( M > 0 \), it follows that \( n^2 > M \) is equivalent to \( n > \sqrt{M} \). A formal proof can now be constructed.

Result 14.6 \[ \lim_{n \to \infty} \left( n^2 + \frac{1}{n} \right) = \infty. \]

Proof Let \( M \) be a positive number. Choose \( N = \lceil \sqrt{M} \rceil \) and let \( n \) be any integer such that \( n > N \). Hence, \( n > \sqrt{M} \) and so \( n^2 > M \). Thus \( n^2 + \frac{1}{n} > n^2 > M \).

SECTION 14.1 EXERCISES

14.1. Give an example of a sequence that is not expressed in terms of trigonometry but whose terms are exactly those of the sequence \( \{\cos(n\pi)\} \).

14.2. Give an example of two sequences different from the sequence \( \{n^2 - n! + |n - 2|\} \) whose first three terms are the same as those of \( \{n^2 - n! + |n - 2|\} \).

14.3. Prove that the sequence \( \{\frac{1}{2^n}\} \) converges to 0.

14.4. Prove that the sequence \( \{\frac{1}{n+1}\} \) converges to 0.

14.5. Prove that the sequence \( \{1 + \frac{1}{n}\} \) converges to 1.

14.6. Prove that the sequence \( \{\frac{n+2}{2n+3}\} \) converges to \( \frac{1}{2} \).

14.7. By definition, \( \lim_{n \to \infty} a_n = L \) if for every \( \epsilon > 0 \), there exists a positive integer \( N \) such that if \( n \) is an integer with \( n > N \), then \( |a_n - L| < \epsilon \). By taking the negation of this definition, write out the meaning of \( \lim_{n \to \infty} a_n \neq L \) using quantifiers. Then write out the meaning of \( \{a_n\} \) diverges using quantifiers.

14.8. Show that the sequence \( \{n^4\} \) diverges to infinity.

14.9. Show that the sequence \( \left\{ \frac{n^4 + 2n}{n^2} \right\} \) diverges to infinity.

14.10. (a) Prove that \( 1 + \frac{1}{2} + \frac{1}{3} + \ldots + \frac{1}{n} < 2\sqrt{n} \) for every positive integer \( n \).

(b) Let \( s_n = \frac{1}{2} + \frac{1}{3} + \ldots + \frac{1}{n} \) for each \( n \in \mathbb{N} \). Prove that the sequence \( \{s_n\} \) converges to 0.

14.11. Prove that if a sequence \( \{s_n\} \) converges to \( L \), then the sequence \( \{s_{n^2}\} \) also converges to \( L \).
14.2 INFINITE SERIES

An important concept in calculus involving sequences is infinite series. For real numbers 
\(a_1, a_2, a_3, \ldots\), we write 
\[ \sum_{k=1}^{\infty} a_k = a_1 + a_2 + a_3 + \cdots \]
to denote an infinite series (often simply called a series). For example,
\[ \sum_{k=1}^{\infty} \frac{1}{k^2} = 1 + \frac{1}{2^2} + \frac{1}{3^2} + \cdots \]
and
\[ \sum_{k=1}^{\infty} \frac{k}{2k^2 + 1} = \frac{1}{3} + \frac{2}{9} + \frac{3}{19} + \cdots \]
are infinite series.

The numbers \(a_1, a_2, a_3, \ldots\) are called the terms of the series 
\[ \sum_{k=1}^{\infty} a_k = a_1 + a_2 + a_3 + \cdots \].

The notation certainly seems to suggest that we are adding the terms \(a_1, a_2, a_3, \ldots\). But what does it mean to add infinitely many numbers? A meaning must be given to this. For this reason, we construct a sequence \(\{s_n\}\), called the sequence of partial sums of the series. Here 
\[ s_1 = a_1, s_2 = a_1 + a_2, s_3 = a_1 + a_2 + a_3 \text{ and, in general, for } n \in \mathbb{N}, \]
\[ s_n = a_1 + a_2 + \cdots + a_n = \sum_{k=1}^{n} a_k. \]

Because \(s_n\) is determined by adding a finite number of terms, there is no confusion in understanding the terms of the sequence \(\{s_n\}\). If the sequence \(\{s_n\}\) converges, say to the number \(L\), then the series \(\sum_{k=1}^{\infty} a_k\) is said to converge to \(L\) and we write \(\sum_{k=1}^{\infty} a_k = L\). This number \(L\) is called the sum of \(\sum_{k=1}^{\infty} a_k\). If \(\{s_n\}\) diverges, then \(\sum_{k=1}^{\infty} a_k\) is said to diverge.

The French mathematician Augustin-Louis Cauchy was one of the most productive mathematicians of the 19th century. Among his many accomplishments was his definition of convergence of infinite series, a definition which is still used today. In his work *Cours d’Analyse*, Cauchy considered the sequence \(\{s_n\}\) of partial sums of a series. He stated the following:

If, for increasing values of \(n\), the sum \(s_n\) approaches indefinitely a certain limit \(s\), the series will be called convergent and this limit in question will be called the sum of the series.

We consider an example of a convergent series.

**Result to Prove** The infinite series \(\sum_{k=1}^{\infty} \frac{1}{k(k+1)}\) converges to 1.

**Proof Strategy** First, we consider the sequence \(\{s_n\}\) of partial sums for this series. Since
\[ \sum_{k=1}^{\infty} \frac{1}{k(k+1)} = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots, \]
Chapter 14  Proofs in Calculus

it follows that \( s_1 = \frac{1}{1 \cdot 2} = \frac{1}{2} \), \( s_2 = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} = \frac{1}{2} + \frac{1}{6} = \frac{2}{3} \) and

\[
s_3 = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} = \frac{1}{2} + \frac{1}{6} + \frac{1}{12} = \frac{3}{4}.
\]

Based on these three terms, it \textit{appears} that \( s_n = \frac{n}{n+1} \) for every positive integer \( n \). We prove that this is indeed the case.

\textbf{Lemma 14.7}  For every positive integer \( n \),

\[
s_n = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{n(n+1)} = \frac{n}{n+1}.
\]

\textbf{Proof of Lemma 14.7}  We proceed by induction. For \( n = 1 \), we have \( s_1 = \frac{1}{1 \cdot 2} = \frac{1}{1+1} \) and the result holds.

Assume that \( s_k = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{k(k+1)} = \frac{k}{k+1} \), where \( k \) is a positive integer. We show that

\[
s_{k+1} = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{k(k+1)} + \frac{1}{(k+1)(k+2)} = \frac{k+1}{k+2}.
\]

Observe that

\[
s_{k+1} = \left[ \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{k(k+1)} \right] + \frac{1}{(k+1)(k+2)}
\]

\[
= \frac{k}{k+1} + \frac{1}{(k+1)(k+2)} = \frac{k(k+2) + 1}{(k+1)(k+2)} = \frac{k^2 + 2k + 1}{(k+1)(k+2)}
\]

\[
= \frac{(k+1)^2}{(k+1)(k+2)} = \frac{k+1}{k+2}.
\]

By the Principle of Mathematical Induction, \( s_n = \frac{n}{n+1} \) for every positive integer \( n \).  

\hfill \blacksquare

There is another way that we might have been able to see that \( s_n = \frac{n}{n+1} \). If we had observed that

\[
a_n = \frac{1}{n(n+1)} = \frac{1}{n} - \frac{1}{n+1},
\]

then \( a_1 = \frac{1}{1 \cdot 2} = 1 - \frac{1}{2}, a_2 = \frac{1}{2 \cdot 3} = \frac{1}{2} - \frac{1}{3}, \) etc. In particular,

\[
s_n = a_1 + a_2 + a_3 + \cdots + a_n
\]

\[
= \left( 1 - \frac{1}{2} \right) + \left( \frac{1}{2} - \frac{1}{3} \right) + \left( \frac{1}{3} - \frac{1}{4} \right) + \cdots + \left( \frac{1}{n} - \frac{1}{n+1} \right)
\]

\[
= 1 - \frac{1}{n+1} = \frac{n}{n+1}.
\]
In any case, since we now know that $s_n = \frac{n}{n+1}$, it remains only to prove that

$$\lim_{n \to \infty} s_n = \lim_{n \to \infty} \frac{n}{n+1} = 1.$$ 

**Lemma to Prove** \( \lim_{n \to \infty} \frac{n}{n+1} = 1. \)

**Proof Strategy** For a given \( \epsilon > 0 \), we are required to find a positive integer \( N \) such that if \( n > N \), then

$$\left| \frac{n}{n+1} - 1 \right| < \epsilon.$$ 

Now,

$$\left| \frac{n}{n+1} - 1 \right| = \left| \frac{n-n-1}{n+1} \right| = \left| \frac{-1}{n+1} \right| = \frac{1}{n+1}.$$ 

The inequality \( \frac{1}{n+1} < \epsilon \) is equivalent to \( n+1 > \frac{1}{\epsilon} \), which in turn is equivalent to \( n > \frac{1}{\epsilon} - 1 \). If \( n > \frac{1}{\epsilon} - 1 \), then \( n > \frac{1}{\epsilon} - 1 \). We can now present a proof of this lemma.

\[ \Box \]

**Lemma 14.8** \( \lim_{n \to \infty} \frac{n}{n+1} = 1. \)

**Proof of Lemma 14.8** Let \( \epsilon > 0 \) be given. Choose \( N = \lceil 1/\epsilon \rceil \) and let \( n > N \). Then \( n > \frac{1}{\epsilon} > \frac{1}{\epsilon} - 1 \). So \( n > \frac{1}{\epsilon} - 1 \). Thus, \( n+1 > \frac{1}{\epsilon} \) and \( \frac{1}{n+1} < \epsilon \). Hence,

$$\left| \frac{n}{n+1} - 1 \right| = \left| \frac{-1}{n+1} \right| = \frac{1}{n+1} < \epsilon.$$ 

\[ \blacksquare \]

We are now prepared to give a proof of the result.

**Result 14.9** The infinite series \( \sum_{k=1}^{\infty} \frac{1}{k(k+1)} \) converges to 1.

**Proof** The \( n \)th term of the sequence \( \{s_n\} \) of partial sums of the series \( \sum_{k=1}^{\infty} \frac{1}{k(k+1)} \) is

$$s_n = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{n(n+1)}.$$ 

By Lemma 14.7,

$$s_n = \frac{1}{1 \cdot 2} + \frac{1}{2 \cdot 3} + \frac{1}{3 \cdot 4} + \cdots + \frac{1}{n(n+1)} = \frac{n}{n+1}.$$
376 Chapter 14 Proofs in Calculus

and so \( s_n = \frac{n}{n+1} \). By Lemma 14.8,

\[
\lim_{n \to \infty} \frac{n}{n+1} = 1.
\]

Since \( \lim_{n \to \infty} s_n = 1 \), it follows that

\[
\sum_{k=1}^{\infty} \frac{1}{k(k+1)} = 1.
\]

We now turn to a divergent series. The series \( \sum_{k=1}^{\infty} \frac{1}{k} = 1 + \frac{1}{2} + \frac{1}{3} + \ldots \) is famous and is called the harmonic series. Indeed, it is probably the best known divergent series.

Result 14.10 The harmonic series \( \sum_{k=1}^{\infty} \frac{1}{k} \) diverges.

**Proof** Assume, to the contrary, that \( \sum_{k=1}^{\infty} \frac{1}{k} \) converges, say to the number \( L \). For each positive integer \( n \), let \( s_n = \sum_{k=1}^{n} \frac{1}{k} \). Hence, the sequence \( \{s_n\} \) of partial sums converges to \( L \).

Therefore, for each \( \epsilon > 0 \), there exists a positive integer \( N \) such that if \( n > N \), then \( |s_n - L| < \epsilon \). Let’s consider \( \epsilon = 1/4 \) and let \( n \) be an integer with \( n > N \). Then

\[
-\frac{1}{4} < s_n - L < \frac{1}{4}.
\]

Since \( 2n > N \), it is also the case that \( |s_{2n} - L| < \frac{1}{4} \) and so \( -\frac{1}{4} < s_{2n} - L < \frac{1}{4} \). Observe that

\[
s_{2n} = s_n + \frac{1}{n+1} + \frac{1}{n+2} + \ldots + \frac{1}{2n} > s_n + n \left( \frac{1}{2n} \right) = s_n + \frac{1}{2}.
\]

Hence,

\[
\frac{1}{4} > s_{2n} - L > s_n + \frac{1}{2} - L = (s_n - L) + \frac{1}{2} > -\frac{1}{4} + \frac{1}{2} = \frac{1}{4},
\]

which is impossible.

**PROOF ANALYSIS** In Result 14.10, we showed that a certain series diverges, that is, it does not converge. Consequently, it is not surprising that we proved this by contradiction. By assuming that the sequence \( \{s_n\} \) converges, this meant that the sequence has a limit \( L \). This tells us that an inequality of the type \( |s_n - L| < \epsilon \) exists for every positive number \( \epsilon \) and for sufficiently large integers \( n \) (which depend on \( \epsilon \)). The goal, of course, was to obtain a contradiction. We did this by making a choice of \( \epsilon \) (\( \epsilon = 1/4 \) worked!) that eventually produced a mathematical impossibility.

\[\Box\]
The harmonic series \( \sum_{k=1}^{\infty} \frac{1}{k} \) not only diverges, it diverges to infinity; that is, if \( \{s_n\} \) is the sequence of partial sums for the harmonic series, then \( \lim_{n \to \infty} s_n = \infty \). We also establish this fact. First, we verify a lemma, which shows once again that mathematical induction can be a useful proof technique in calculus.

**Lemma 14.11** Let \( s_n = \sum_{k=1}^{n} \frac{1}{k} = 1 + \frac{1}{2} + \cdots + \frac{1}{n} \), where \( n \in \mathbb{N} \). Then \( s_{2n} \geq 1 + \frac{n}{2} \) for every positive integer \( n \).

**Proof** We proceed by induction. For \( n = 1 \), \( s_2 = 1 + \frac{1}{2} \) and so the result holds for \( n = 1 \). Assume that \( s_{2k} \geq 1 + \frac{k}{2} \), where \( k \in \mathbb{N} \). We show that \( s_{2k+1} \geq 1 + \frac{k+1}{2} \). Now observe that

\[
\begin{align*}
s_{2k+1} &= 1 + \frac{1}{2} + \cdots + \frac{1}{2k+1} \\
&= s_{2k} + \frac{1}{2k+1} + \frac{1}{2k+2} + \cdots + \frac{1}{2k+1} \\
&\geq s_{2k} + \frac{1}{2k+1} + \frac{1}{2k+2} + \cdots + \frac{1}{2k+1} \\
&= s_{2k} + \frac{2k}{2k+1} = s_{2k} + \frac{1}{2} \\
&\geq 1 + \frac{k}{2} + \frac{1}{2} = 1 + \frac{k+1}{2}.
\end{align*}
\]

By the Principle of Mathematical Induction, \( s_{2n} \geq 1 + \frac{n}{2} \) for every positive integer \( n \).

**Result 14.12** The harmonic series \( \sum_{k=1}^{\infty} \frac{1}{k} \) diverges to infinity.

**Proof** For \( n \in \mathbb{N} \), let \( s_n = \sum_{k=1}^{n} \frac{1}{k} \). Thus, \( \{s_n\} \) is the sequence of partial sums for the harmonic series. We show that \( \lim_{n \to \infty} s_n = \infty \). Let \( M \) be a positive integer and choose \( N = 2^{2M} \). Let \( n > N \). Then, using Lemma 14.11, we have

\[
\begin{align*}
s_n &= 1 + \frac{1}{2} + \cdots + \frac{1}{N} + \frac{1}{N+1} + \cdots + \frac{1}{n} \\
&= s_N + \frac{1}{N+1} + \frac{1}{N+2} + \cdots + \frac{1}{n} \\
&> s_N = s_{2^M} \geq 1 + \frac{2M}{2} > M.
\end{align*}
\]
SECTION 14.2 EXERCISES

14.12. Prove that the series \( \sum_{k=1}^{\infty} \frac{1}{(3k-2)(3k+1)} \) converges and determine its sum by
   (a) computing the first few terms of the sequence \( \{s_n\} \) of partial sums and conjecturing a formula for \( s_n \);
   (b) using mathematical induction to verify that your conjecture in (a) is correct;
   (c) completing the proof.

14.13. Prove that the series \( \sum_{k=1}^{\infty} \frac{1}{2^k} \) converges and determine its sum by
   (a) computing the first few terms of the sequence \( \{s_n\} \) of partial sums and conjecturing a formula for \( s_n \);
   (b) using mathematical induction to verify that your conjecture in (a) is correct;
   (c) completing the proof.

14.14. The terms \( a_1, a_2, a_3, \ldots \) of the series \( \sum_{k=1}^{\infty} a_k \) are defined recursively by
   \[ a_1 = \frac{1}{6}, \quad a_n = a_{n-1} - \frac{2}{n(n+1)(n+2)} \]
   for \( n \geq 2 \). Prove that \( \sum_{k=1}^{\infty} a_k \) converges and determine its value.

14.15. Prove that the series \( \sum_{k=1}^{\infty} \frac{k+3}{(k+1)^2} \) diverges to infinity.

14.16. (a) Prove that if \( \sum_{k=1}^{\infty} a_k \) is a convergent series, then \( \lim_{n \to \infty} a_n = 0 \).
   (b) Show that the converse of the result in (a) is false.

14.17. Let \( \sum_{k=1}^{\infty} a_k \) be an infinite series whose sequence of partial sums is \( \{s_n\} \) where \( s_n = \frac{3n}{4n^2+1} \).
   (a) What is the series \( \sum_{k=1}^{\infty} a_k \)?
   (b) Determine the sum \( s \) of \( \sum_{k=1}^{\infty} a_k \) and prove that \( \sum_{k=1}^{\infty} a_k = s \).

14.3 LIMITS OF FUNCTIONS

We now turn to another common type of limit problem (perhaps the most common). Here we consider functions \( f : X \to \mathbb{R} \), where \( X \subseteq \mathbb{R} \), and study the behavior of such a function \( f \) near some real number (point) \( a \). For the present, we are not concerned whether \( a \in X \), but since we are concerned about the numbers \( f(x) \) for real numbers \( x \) near \( a \), it is necessary that \( f \) is defined in some “deleted neighborhood” of \( a \). By a deleted neighborhood of \( a \), we mean a set of the type \((a - \delta, a) \cup (a, a + \delta) = (a - \delta, a + \delta) - \{a\} \subseteq X \) for some positive real number \( \delta \) (the Greek letter delta). (See Figure 14.2.) It may actually be the case that \((a - \delta, a + \delta) \subseteq X \) for some \( \delta > 0 \). For example, if \( f : X \to \mathbb{R} \) is defined by \( f(x) = \frac{|x|}{x} \) and we are interested in the behavior of \( f \) near 0, then \( 0 \notin X \). In fact, it might very well be that \( X = \mathbb{R} - \{0\} \), in which case, \((-\delta, 0) \cup (0, \delta) \subseteq X \) for every positive real number \( \delta \). On the other hand, if \( f : X \to \mathbb{R} \) is defined by \( f(x) = \frac{x}{x^2 - 1} \) and, once again, we are interested in the behavior of \( f \) near 0, then \( 1, -1 \notin X \). A natural choice for \( X \) is \( \mathbb{R} - \{1, -1\} \), in which case \((-\delta, \delta) \subseteq X \) for every real number \( \delta \) such that \( 0 < \delta \leq 1 \).
We are now prepared to present the definition of the limit of a function. Let \( f \) be a real-valued function defined on a set \( X \) of real numbers. Also, let \( a \in \mathbb{R} \) such that \( f \) is defined in some deleted neighborhood of \( a \). Then we say that the real number \( L \) is the limit of \( f(x) \) as \( x \) approaches \( a \), written \( \lim_{x \to a} f(x) = L \), if the closer \( x \) is to \( a \), the closer \( f(x) \) is to \( L \). The vagueness of the word “closer” here too requires a considerably more precise definition. Let the positive number \( \varepsilon \) indicate how close \( f(x) \) is required to be to \( L \), that is, we require that \( |f(x) - L| < \varepsilon \). Then the claim is that if \( x \) is sufficiently close to \( a \), then \( |f(x) - L| < \varepsilon \). We use the positive number \( \delta \) to represent how close \( x \) must be to \( a \) in order for the inequality \( |f(x) - L| < \varepsilon \) to be satisfied, recalling that we are not concerned about how, or even if, \( f \) is defined at \( a \).

More precisely then, \( L \) is the limit of \( f(x) \) as \( x \) approaches \( a \), written \( \lim_{x \to a} f(x) = L \), if for every real number \( \varepsilon > 0 \), there exists a real number \( \delta > 0 \) such that for every real number \( x \) with \( 0 < |x - a| < \delta \), it follows that \( |f(x) - L| < \varepsilon \). This implies that if \( 0 < |x - a| < \delta \), then certainly \( f(x) \) is defined. If there exists a number \( L \) such that \( \lim_{x \to a} f(x) = L \), then we say that the limit \( \lim_{x \to a} f(x) \) exists and is equal to \( L \); otherwise, this limit does not exist. Thus, to show that \( \lim_{x \to a} f(x) = L \), it is necessary to specify \( \varepsilon > 0 \) first and then show the existence of a real number \( \delta > 0 \). Ordinarily, the smaller the value of \( \varepsilon \), the smaller the value of \( \delta \). However, we must be certain that the number \( \delta \) selected satisfies the requirement regardless of how small (or large) \( \varepsilon \) may be. Even though our choice of \( \delta \) depends on \( \varepsilon \), it should not depend on which real number \( x \) with \( 0 < |x - a| < \delta \) is being considered.

Accordingly, if \( \lim_{x \to a} f(x) = L \), then for a given \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that if \( x \) is any number in the open interval \( (a - \delta, a + \delta) \) that is different from \( a \), then \( f(x) \) is a number in the interval \( (L - \varepsilon, L + \varepsilon) \). This geometric interpretation of the definition of limit is illustrated in Figure 14.3.

We illustrate these ideas with an example.

\[
\begin{array}{c}
L - \varepsilon & f(x) & L \\
\downarrow & \bullet & \downarrow \\
\hline
\hline
a - \delta & x & a + \delta \\
\hline
\end{array}
\]

\( \Rightarrow \) \( y \)-axis

\( \Rightarrow \) \( x \)-axis

**Figure 14.3** A geometric interpretation of \( \lim_{x \to a} f(x) = L \).

**Result to Prove** \( \lim_{x \to 4} (3x - 7) = 5 \).
Chapter 14  Proofs in Calculus

PROOF STRATEGY  Before giving a formal proof of this limit, let’s discuss the procedure we will use. The proof begins by letting \( \varepsilon > 0 \) be given. What we are required to do is to find a number \( \delta > 0 \) such that if \( 0 < |x - 4| < \delta \), then \( |(3x - 7) - 5| < \varepsilon \) or, equivalently, \( |3(x - 4)| < \varepsilon \). This is also equivalent to \( |3| \cdot |x - 4| < \varepsilon \) and to \( |x - 4| < \varepsilon /3 \). This suggests our choice of \( \delta \). We can now give a proof.

♦

Result 14.13  \( \lim_{x \to 4} (3x - 7) = 5 \).

Proof  Let \( \varepsilon > 0 \) be given. Choose \( \delta = \varepsilon /3 \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 4| < \delta = \varepsilon /3 \). Then

\[
|(3x - 7) - 5| = |3x - 12| = |3(x - 4)| < 3(\varepsilon /3) = \varepsilon .
\]

Let’s consider another example.

Result to Prove  \( \lim_{x \to -3} (-2x + 1) = 7 \).

PROOF STRATEGY  First we do some preliminary algebra. The inequality \(|(-2x + 1) - 7| < \varepsilon \) is equivalent to \(|2x - 6| < \varepsilon \) and to \(2|x + 3| < \varepsilon \). This suggests a desired value of \( \delta \). We can now give a proof.

♦

Result 14.14  \( \lim_{x \to -3} (-2x + 1) = 7 \).

Proof  Let \( \varepsilon > 0 \) be given and choose \( \delta = \varepsilon /2 \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - (-3)| < \delta = \varepsilon /2 \), so \( 0 < |x + 3| < \varepsilon /2 \). Then

\[
|(-2x + 1) - 7| = |2x - 6| = |2(x + 3)| = 2|x + 3| < 2(\varepsilon /2) = \varepsilon .
\]

The two examples that we have seen thus far should tell us how to proceed when the function is linear (that is, \( f(x) = ax + b \), where \( a, b \in \mathbb{R} \)). We now present a slight variation of this.

Result to Prove  \( \lim_{x \to \frac{3}{2}} \frac{4x^2 - 9}{2x - 3} = 6 \).

PROOF STRATEGY  In this example, \(|f(x) - L| < \varepsilon \) becomes \( \frac{|4x^2 - 9|}{2x - 3} < \varepsilon \) or, after simplifying,

\[
\frac{|(2x + 3)(2x - 3)|}{2x - 3} - 6 < \varepsilon .
\]

However, since the numbers \( x \) are in a deleted neighborhood of \( \frac{3}{2} \), it follows that \( x \neq \frac{3}{2} \) and thus \( 2x - 3 \neq 0 \). Thus,

\[
\frac{|(2x + 3)(2x - 3)|}{2x - 3} - 6 < \varepsilon \text{ becomes } |(2x + 3) - 6| < \varepsilon \text{ or } |2x - 3| < \varepsilon .
\]

Therefore, \( 2|x - 3/2| < \varepsilon \) and \( |x - 3/2| < \varepsilon /2 \). We are now prepared to give a proof.

♦

Result 14.15  \( \lim_{x \to \frac{3}{2}} \frac{4x^2 - 9}{2x - 3} = 6 \).
Let $\epsilon > 0$ be given and choose $\delta = \epsilon/2$. Let $x \in \mathbb{R}$ such that $0 < |x - 3/2| < \delta = \epsilon/2$. So $2|x - 3/2| < \epsilon$ and $|2x - 3| < \epsilon$. Hence, $|(2x + 3) - 6| < \epsilon$. Since $2x - 3 \neq 0$, it follows that \[
\left\lvert \frac{(2x + 3)(2x - 3)}{2x - 3} - 6 \right\rvert < \epsilon \text{ and so } \left\lvert \frac{4x^2 - 9}{2x - 3} - 6 \right\rvert < \epsilon. \]

We now turn to a limit of a quadratic function.

**Result to Prove**  
\[
\lim_{x \to 3} x^2 = 9.
\]

**Proof**  
Once again for a given $\epsilon > 0$, we are required to find $\delta > 0$ such that if $0 < |x - 3| < \delta$, then $|x^2 - 9| < \epsilon$. To find an appropriate choice of $\delta$ in terms of $\epsilon$, we begin with $|x^2 - 9| < \epsilon$. We wish to work the expression $|x - 3|$ into this inequality. Actually, this is quite easy since $|x^2 - 9| < \epsilon$ is equivalent to $|x - 3||x + 3| < \epsilon$. This might make us think of writing $|x - 3| < \frac{\epsilon}{|x + 3|}$ and choosing $\delta = \frac{\epsilon}{|x + 3|}$. However, $\delta$ is required to be a positive number (a constant) that depends on $\epsilon$ but is not a function of $x$. The expression $|x + 3|$ can be eliminated though, as we now show. Since it is our choice how to select $\delta$, we can certainly require $\delta \leq 1$, which we do. Thus, $|x - 3| < 1$ and so $-1 < x - 3 < 1$. Hence, $2 < x < 4$. Thus, $5 < x + 3 < 7$ and so $|x + 3| < 7$. So, under this restriction for $\delta$, it follows that $|x - 3||x + 3| < 7|x - 3|$. Now if $7|x - 3| < \epsilon$, that is, if $|x - 3| < \epsilon/7$, then it will certainly follow that $|x - 3||x + 3| < \epsilon$. Arriving at this inequality required that both $|x - 3| < 1$ and $|x - 3| < \epsilon/7$. This suggests an appropriate choice of $\delta$.

**Result 14.16**  
\[
\lim_{x \to 3} x^2 = 9.
\]

**Proof**  
Let $\epsilon > 0$ be given and choose $\delta = \min(1, \epsilon/7)$. Let $x \in \mathbb{R}$ such that $0 < |x - 3| < \delta = \min(1, \epsilon/7)$. Since $|x - 3| < 1$, it follows that $-1 < x - 3 < 1$ and so $5 < x + 3 < 7$. In particular, $|x + 3| < 7$. Because $|x - 3| < \epsilon/7$, it follows that $|x^2 - 9| = |x - 3||x + 3| < |x - 3| \cdot 7 < (\epsilon/7) \cdot 7 = \epsilon$.

We have now seen four proofs of limits of type $\lim f(x) = L$. In Result 14.13, we chose $\delta = \epsilon/3$ for the given $\epsilon > 0$ and in Result 14.14, we chose $\delta = \epsilon/2$. In each case, if we had considered a different value of $a$ for the same function, then the same choice of $\delta$ would be successful. This is because the function is linear in each case. In Result 14.15, for a given $\epsilon > 0$, the selection of $\delta = \epsilon/2$ would also be successful if $a \neq 3/2$, provided $3/2 \neq (a - \delta, a + \delta)$. This is because the function $f$ in Result 14.15 defined by $f(x) = (4x^2 - 9)/(2x - 3)$ is “nearly linear,” that is, $f(x) = 2x + 3$ if $x \neq 3/2$ and $f(3/2)$ is not defined. However, our choice of $\delta = \epsilon/7$ in the proof of Result 14.16 depended on $a = 3$; that is, if $a \neq 3$, a different choice of $\delta$ is needed. For example, if we were to prove that $\lim x^2 = 16$, then for a given $\epsilon > 0$, an appropriate choice for $\delta$ is $\min(1, \epsilon/9)$.

Next, we consider a limit involving a polynomial function of a higher degree.

**Result to Prove**  
\[
\lim_{x \to 2} (x^3 - 2x^3 - 3x - 7) = 3.
\]
For a given \( \epsilon > 0 \), we are required to show that \(|(x^5 - 2x^3 - 3x - 7) - 3| < \epsilon \) if \( 0 < |x - 2| < \delta \) for a suitable choice of \( \delta > 0 \). We then need to work \(|x - 2|\) into the expression \(|x^5 - 2x^3 - 3x - 10|\). Dividing \( x^5 - 2x^3 - 3x - 10 \) by \( x - 2 \), we obtain \( x^5 - 2x^3 - 3x - 10 = (x - 2)(x^4 + 2x^3 + 2x^2 + 4x + 5) \). Hence, we have
\[
|x^5 - 2x^3 - 3x - 10| = |x - 2||x^4 + 2x^3 + 2x^2 + 4x + 5|.
\]
Thus, we seek an upper bound for \(|x^4 + 2x^3 + 2x^2 + 4x + 5|\). To do this, we impose a restriction on \( \delta \); namely, we require that \( \delta \leq 1 \). Thus, \(|x - 2| < \delta \leq 1 \). So, \(-1 < x - 2 < 1 \) and \( 1 < x < 3 \). Hence,
\[
|x^4 + 2x^3 + 2x^2 + 4x + 5| \leq |x^4| + |2x^3| + |2x^2| + |4x| + |5| < 170.
\]
We are now prepared to prove Result 14.17.

**Result 14.17**
\[
\lim_{x \to 2} (x^5 - 2x^3 - 3x - 7) = 3.
\]

**Proof**
Let \( \epsilon > 0 \) be given and choose \( \delta = \min(1, \epsilon/170) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 2| < \delta = \min(1, \epsilon/170) \). Since \(|x - 2| < 1\), it follows that \( 1 < x < 3 \) and so
\[
|x^4 + 2x^3 + 2x^2 + 4x + 5| \leq |x^4| + |2x^3| + |2x^2| + |4x| + |5| < 170.
\]
Since \(|x - 2| < \epsilon/170\), we have
\[
|(x^5 - 2x^3 - 3x - 7) - 3| = |x^5 - 2x^3 - 3x - 10| = |x - 2||x^4 + 2x^3 + 2x^2 + 4x + 5| < (\epsilon/170) \cdot 170 = \epsilon.
\]

Our next example involves a rational function (the ratio of two polynomials).

**Result to Prove**
\[
\lim_{x \to 1} \frac{x^2 + 1}{x^2 + 4} = \frac{2}{5}.
\]

**Proof Strategy**
First observe that
\[
\left| \frac{x^2 + 1}{x^2 + 4} - \frac{2}{5} \right| = \left| \frac{5(x^2 + 1) - 2(x^2 + 4)}{5(x^2 + 4)} \right| = \left| \frac{3x^2 - 3}{5(x^2 + 4)} \right| = \frac{3|x - 1||x + 1|}{5(x^2 + 4)}.
\]
Hence, it is necessary to find an upper bound for \( \frac{3|x + 1|}{5(x^2 + 4)} \). Once again we restrict \( \delta \) so that \( \delta \leq 1 \). Then \(|x - 1| < 1 \) or \( 0 < x < 2 \). Hence, \( 1 < x + 1 < 3 \) and so \( 3|x + 1| < 9 \). Also, since \( x > 0 \), it follows that \( 5(x^2 + 4) > 20 \). Thus, \( \frac{1}{5(x^2 + 4)} < \frac{1}{20} \) and so
\[
\frac{3|x + 1|}{5(x^2 + 4)} < 9 \left( \frac{1}{20} \right) = \frac{9}{20}.
\]
We now present a proof of this result.

**Result 14.18**
\[
\lim_{x \to 1} \frac{x^2 + 1}{x^2 + 4} = \frac{2}{5}.
\]
14.3 Limits of Functions

**Proof** Let $\epsilon > 0$ be given and choose $\delta = \min(1, 20\epsilon/9)$. Let $x \in \mathbb{R}$ such that $0 < |x - 1| < \delta$. Since $|x - 1| < 1$, we have $0 < x < 2$ and $1 < x + 1 < 3$. Hence, $3|x + 1| \leq 3 \cdot 3 = 9$ and $5(x^2 + 4) > 20$, so $\frac{1}{5(x^2 + 4)} < \frac{1}{20}$. Therefore, $\frac{3|x + 1|}{5(x^2 + 4)} < 9/20$. Since $|x - 1| < 20\epsilon/9$, it follows that

$$
\frac{|x^2 + 1|}{x^2 + 4} - 2 \left| \frac{5(x^2 + 1) - 2(x^2 + 4)}{5(x^2 + 4)} \right| = \frac{|3x^2 - 3|}{5(x^2 + 4)}
$$

$$
\leq \frac{3|x - 1||x + 1|}{5(x^2 + 4)} < \frac{20\epsilon}{9} \cdot \frac{9}{20} = \epsilon.
$$

We now present one additional example on this topic.

**Example 14.19** What would be a reasonable conjecture for $\lim_{x \to 1} \frac{x^2 - 1}{2x - 1}$?

**Solution** Since it appears that $\lim_{x \to 1}(x^2 - 1) = 0$ and $\lim_{x \to 1}(2x - 1) = 1$, we would expect that $\lim_{x \to 1} \frac{x^2 - 1}{2x - 1} = 0/1 = 0$.

Let’s now give a formal proof of this, beginning with a plan for a proof.

**PROOF STRATEGY** To verify that the limit in Example 14.19 is 0, we show for a given $\epsilon > 0$ that there exists $\delta > 0$ such that if $0 < |x - 1| < \delta$, then

$$
\left| \frac{x^2 - 1}{2x - 1} - 0 \right| = \left| \frac{x^2 - 1}{2x - 1} \right| < \epsilon.
$$

Observe that

$$
\left| \frac{x^2 - 1}{2x - 1} \right| = \left| \frac{(x - 1)(x + 1)}{2x - 1} \right| = \frac{|x + 1|}{|2x - 1|}|x - 1|.
$$

Proceeding as before, we find an upper bound for $\frac{|x + 1|}{|2x - 1|}$. Ordinarily, we might restrict $\delta \leq 1$, as before, but in this situation, we have a problem. If $\delta \leq 1$, then $0 < |x - 1| < \delta$ and so $|x - 1| < 1$. Thus, $0 < x < 2$ or $x \in (0, 2)$. However, this interval of real numbers includes $1/2$ and $|x + 1|/|2x - 1|$ is not defined when $x = 1/2$. Thus, we place a tighter restriction on $\delta$. The restriction $\delta \leq 1/2$ is not suitable either, for if $|x - 1| < \delta \leq 1/2$, then $1/2 < x < 3/2$. Even though $|x + 1|/|2x - 1|$ is defined for all real numbers $x$ in this interval, this expression becomes arbitrarily large if $x$ is arbitrarily close to $1/2$, allowing $|2x - 1|$ to be arbitrarily close to 0. That is, we cannot find an upper bound for $|x + 1|/|2x - 1|$ if $\delta = 1/2$. Hence, we require that $\delta \leq 1/4$, say, and so $|x - 1| < \delta \leq 1/4$. Thus, $3/4 < x < 5/4$. Hence, $|x + 1| < 9/4$. Also, $|2x - 1| > 2(\frac{3}{4}) - 1 = 1/2$ and so $\frac{1}{|2x - 1|} < 2$. Therefore, $\frac{|x + 1|}{|2x - 1|} < \frac{9}{4} \cdot \frac{9}{2} = \frac{9}{2}$. 

$\blacksquare$
Chapter 14  Proofs in Calculus

Result 14.20 \( \lim_{x \to 1} \frac{x^2 - 1}{2x - 1} = 0. \)

Proof Let \( \epsilon > 0 \) be given and choose \( \delta = \min(1/4, 2\epsilon/9) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 1| < \delta \). Since \( \delta \leq 1/4 \), it follows that \( |x - 1| < 1/4 \) and so \( 3/4 < x < 5/4 \). Hence, \( |x + 1| < 5/4 + 1 = 9/4 \). Also, \( |2x - 1| > 2 \left( \frac{3}{4} \right) - 1 = 1/2 \) and so \( \frac{1}{|2x - 1|} < 2 \). Therefore, \( \frac{|x^2 - 1|}{|2x - 1|} = \frac{|x + 1|}{|2x - 1|} |x - 1| < \frac{2\epsilon}{9} \cdot \frac{9}{2} = \epsilon. \)

Next we consider a limit problem where the limit does not exist.

Result to Prove \( \lim_{x \to 0} \frac{1}{x} \) does not exist.

Proof Strategy As expected, we will give a proof by contradiction. If \( \lim_{x \to 0} \frac{1}{x} \) does exist, then there exists a real number \( L \) such that \( \lim_{x \to 0} \frac{1}{x} = L \). Hence, for every \( \epsilon > 0 \), there exists \( \delta > 0 \) such that if \( 0 < |x| < \delta \), then \( \left| \frac{1}{x} - L \right| < \epsilon \). For numbers \( x \) “close” to 0, it certainly appears that \( \frac{1}{x} \) is “large” (in absolute value). Hence, regardless of the value of \( \epsilon \), it seems that there should be a real number \( x \) with \( 0 < |x| < \delta \) such that \( \left| \frac{1}{x} - L \right| \geq \epsilon \). It is our plan to show that this is indeed the case. Thus, we choose \( \epsilon = 1 \), for example, and show that no desired \( \delta \) can be found.

Result 14.21 \( \lim_{x \to 0} \frac{1}{x} \) does not exist.

Proof Assume, to the contrary, that \( \lim_{x \to 0} \frac{1}{x} \) exists. Then there exists a real number \( L \) such that \( \lim_{x \to 0} \frac{1}{x} = L \). Let \( \epsilon = 1 \). Then there exists \( \delta > 0 \) such that if \( x \) is a real number for which \( 0 < |x| < \delta \), then \( \left| \frac{1}{x} - L \right| < \epsilon = 1 \). Choose an integer \( n \) such that \( n > \lceil 1/\delta \rceil \geq 1 \). Since \( n > 1/\delta \), it follows that \( 0 < 1/n < \delta \). We consider two cases.

Case 1. \( L \leq 0 \). Let \( x = 1/n \). So \( 0 < |x| < \delta \). Since \( -L \geq 0 \), it follows that

\[ \left| \frac{1}{x} - L \right| = \left| n - L \right| = n - L \geq n > 1 = \epsilon, \]

which is a contradiction.
Case 2. Let \( x = -1/n \). So, 0 < \(|x| < \delta \). Thus,

\[
\left| \frac{1}{x} - L \right| = \left| -n - L \right| = \left| - (n + L) \right| = n + L > n > 1 = \epsilon,
\]

producing a contradiction in this case as well.

**Result to Prove** Let \( f(x) = |x|/x \), where \( x \in \mathbb{R} \) and \( x \neq 0 \). Then \( \lim_{x \to 0} f(x) \) does not exist.

**Proof Strategy** The graph of this function is shown in Figure 14.4. If \( x > 0 \), then \( f(x) = |x|/x = x/x = 1 \); while if \( x < 0 \), then \( f(x) = |x|/x = -x/x = -1 \). Hence, there are numbers \( x \) that are “near” 0 such that \( f(x) = 1 \) and numbers \( x \) that are “near” 0 such that \( f(x) = -1 \). This suggests a proof.

![Figure 14.4](image-url) The graph of the function \( f(x) = |x|/x \)

**Result 14.22** Let \( f(x) = |x|/x \), where \( x \in \mathbb{R} \) and \( x \neq 0 \). Then \( \lim_{x \to 0} f(x) \) does not exist.

**Proof** Assume, to the contrary, that \( \lim_{x \to 0} f(x) \) exists. Then there exists a real number \( L \) such that \( \lim_{x \to 0} f(x) = L \). Let \( \epsilon = 1 \). Then there exists \( \delta > 0 \) such that if \( x \) is a real number satisfying \( 0 < |x - 0| = |x| < \delta \), then \( |f(x) - L| < \epsilon = 1 \). We consider two cases.

**Case 1.** \( L \geq 0 \). Consider \( x = -\delta/2 \). Then \( |x| = \delta/2 < \delta \). However, \( f(x) = f(-\delta/2) = (\delta/2)/(-\delta/2) = -1 \). So \( |f(x) - L| = |-1 - L| = 1 + L \geq 1 \), a contradiction.

**Case 2.** \( L < 0 \). Let \( x = \delta/2 \). Then \( |x| = \delta/2 < \delta \). Also, \( f(x) = f(\delta/2) = (\delta/2)/\delta/2 = 1 \). So \( |f(x) - L| = |1 - L| = 1 - L > 1 \), a contradiction.

**SECTION 14.3 EXERCISES**

14.18. Give an \( \epsilon - \delta \) proof that \( \lim_{x \to 2} (\frac{3}{2} x + 1) = 4 \).

14.19. Give an \( \epsilon - \delta \) proof that \( \lim_{x \to -1} (3x - 5) = -8 \).

14.20. Give an \( \epsilon - \delta \) proof that \( \lim_{x \to 2} (2x^2 - x - 5) = 1 \).
386 Chapter 14 Proofs in Calculus

14.21. Give an \(\varepsilon - \delta\) proof that \(\lim_{x \to 2} x^3 = 8\).
14.22. Determine \(\lim_{x \to -1} \frac{1}{3x^3}\) and verify that your answer is correct with an \(\varepsilon - \delta\) proof.
14.23. Give an \(\varepsilon - \delta\) proof that \(\lim_{x \to 3} \frac{3x+1}{4x+3} = \frac{2}{3}\).
14.24. Determine \(\lim_{x \to -3} \frac{x^2-2x-3}{x^2-8x+15}\) and verify that your answer is correct with an \(\varepsilon - \delta\) proof.
14.25. Show that \(\lim_{x \to 0} \frac{1}{x}\) does not exist.
14.26. The function \(f : \mathbb{R} \to \mathbb{R}\) is defined by

\[ f(x) = \begin{cases} 
1 & x < 3 \\
1.5 & x = 3 \\
2 & x > 3.
\end{cases} \]

(a) Determine whether \(\lim_{x \to 3} f(x)\) exists and verify your answer.
(b) Determine whether \(\lim_{x \to \frac{1}{2}} f(x)\) exists and verify your answer.

14.27. A function \(g : \mathbb{R} \to \mathbb{R}\) is bounded if there exists a positive real number \(B\) such that \(|g(x)| < B\) for each \(x \in \mathbb{R}\).

(a) Let \(g : \mathbb{R} \to \mathbb{R}\) be a bounded function and suppose that \(f : \mathbb{R} \to \mathbb{R}\) and \(a \in \mathbb{R}\) such that \(\lim_{x \to a} f(x) = 0\). Prove that \(\lim_{x \to a} f(x)g(x) = 0\).
(b) Use the result in (a) to determine \(\lim_{x \to 0} x^2 \sin \left(\frac{1}{x}\right)\).

14.28. Suppose that \(\lim_{x \to a} f(x) = L\), where \(L > 0\). Prove that \(\lim_{x \to a} \sqrt{f(x)} = \sqrt{L}\).

14.29. Suppose that \(f : \mathbb{R} \to \mathbb{R}\) is a function such that \(\lim_{x \to 0} f(x) = L\).

(a) Let \(c \in \mathbb{R}\). Prove that \(\lim_{x \to c} f(x - c) = L\).
(b) Suppose that \(f\) has the property that \(f(a + b) = f(a) + f(b)\) for all \(a, b \in \mathbb{R}\). Use the result in (a) to prove that \(\lim_{x \to c} f(x)\) exists for all \(c \in \mathbb{R}\).

14.30. Let \(f : \mathbb{R} \to \mathbb{R}\) be a function.

(a) Prove that if \(\lim_{x \to a} f(x) = L\), then \(\lim_{x \to a} |f(x)| = |L|\).
(b) Prove or disprove: If \(\lim_{x \to a} |f(x)| = |L|\), then \(\lim_{x \to a} f(x)\) exists.

14.4 Fundamental Properties of Limits of Functions

If we were to continue computing limits, then it would be essential to have some theorems at our disposal that would allow us to compute limits more rapidly. We now present some theorems that will allow us to determine limits more easily. We begin with a standard theorem on limits of sums of functions.

**Theorem to Prove**

If \(\lim_{x \to a} f(x) = L\) and \(\lim_{x \to a} g(x) = M\), then

\[ \lim_{x \to a} (f(x) + g(x)) = L + M. \]

**Proof Strategy**

In this case, we are required to show, for a given \(\varepsilon > 0\), that \(|(f(x) + g(x)) - (L + M)| < \varepsilon\) if \(0 < |x - a| < \delta\) for a suitable choice of \(\delta > 0\). Now,

\[ |(f(x) + g(x)) - (L + M)| = |(f(x) - L) + (g(x) - M)| \leq |f(x) - L| + |g(x) - M|. \]
Hence, if we can show that both \(|f(x) - L| < \epsilon/2\) and \(|g(x) - M| < \epsilon/2\), for example, then we will have obtained the desired inequality. However, because of the hypothesis, this can be accomplished. We now make all of this precise.

**Theorem 14.23** If \(\lim_{x \to a} f(x) = L\) and \(\lim_{x \to a} g(x) = M\), then

\[
\lim_{x \to a} (f(x) + g(x)) = L + M.
\]

**Proof** Let \(\epsilon > 0\). Since \(\epsilon/2 > 0\), there exists \(\delta_1 > 0\) such that if \(0 < |x - a| < \delta_1\), then \(|f(x) - L| < \epsilon/2\). Also, there exists \(\delta_2 > 0\) such that if \(0 < |x - a| < \delta_2\), then \(|g(x) - M| < \epsilon/2\). Choose \(\delta = \min(\delta_1, \delta_2)\) and let \(x \in \mathbb{R}\) such that \(0 < |x - a| < \delta\). Since \(0 < |x - a| < \delta\), it follows that both \(0 < |x - a| < \delta_1\) and \(0 < |x - a| < \delta_2\). Therefore,

\[
|(f(x) + g(x)) - (L + M)| = |(f(x) - L) + (g(x) - M)|
\]

\[
\leq |f(x) - L| + |g(x) - M| < \epsilon/2 + \epsilon/2 = \epsilon.
\]

Theorem 14.23 states that the limit of the sum of two functions is the sum of their limits. Next we show that this is also true for products. Before getting to this theorem, let’s see what would be involved to prove it. Let \(\lim_{x \to a} f(x) = L\) and \(\lim_{x \to a} g(x) = M\). This means that we can make the expressions \(|f(x) - L|\) and \(|g(x) - M|\) as small as we wish. Our goal is to show that we can make \(|f(x) \cdot g(x) - LM|\) as small as we wish, say less than \(\epsilon\) for every given \(\epsilon > 0\). The question then becomes how to use what we know about \(|f(x) - L|\) and \(|g(x) - M|\) as we consider \(|f(x) \cdot g(x) - LM|\). A common way to do this is to add and subtract the same quantity to and from \(f(x) \cdot g(x) - LM\). For example,

\[
|f(x) \cdot g(x) - LM| = |f(x) \cdot g(x) - f(x) \cdot M + f(x) \cdot M - LM|
\]

\[
= |f(x)(g(x) - M) + (f(x) - L)M|.
\]

If we can make each of \(|f(x)||g(x) - M|\) and \(|f(x) - L||M|\) less than \(\epsilon/2\), say, then we will have accomplished our goal. Since \(|M|\) is a nonnegative constant and \(|f(x) - L|\) and \(|g(x) - M|\) can be made arbitrarily small, only \(|f(x)|\) is in question. In fact, all that is required to show is that \(f(x)\) can be bounded in a deleted neighborhood of \(a\), that is, \(|f(x)| \leq B\) for some constant \(B > 0\).

**Lemma 14.24** Suppose that \(\lim_{x \to a} f(x) = L\). Then there exists \(\delta > 0\) such that if \(0 < |x - a| < \delta\), then \(|f(x)| < 1 + |L|\).

**Proof** Let \(\epsilon = 1\). Then there exists \(\delta > 0\) such that if \(0 < |x - a| < \delta\), then \(|f(x) - L| < 1\). Thus

\[
|f(x)| = |f(x) - L + L| \leq |f(x) - L| + |L| < 1 + |L|.
\]

We are now prepared to show that the limit of the product of two functions is the product of their limits.

**Theorem to Prove** If \(\lim_{x \to a} f(x) = L\) and \(\lim_{x \to a} g(x) = M\), then \(\lim_{x \to a} f(x) \cdot g(x) = LM\).
As we discussed earlier,

\[ |f(x) \cdot g(x) - LM| = |f(x) \cdot g(x) - f(x) \cdot M + f(x) \cdot M - LM| \]
\[ = |f(x)(g(x) - M) + (f(x) - L)M| \]
\[ \leq |f(x)||g(x) - M| + |f(x) - L||M|. \]

For a given \( \epsilon > 0 \), we show that each of \( |f(x)||g(x) - M| \) and \( |f(x) - L||M| \) can be made less than \( \epsilon/2 \), which will give us a proof of the result. Of course, this follows immediately for \( |f(x) - L||M| \) if \( M = 0 \). Otherwise, we can make \( |f(x) - L| \) less than \( \epsilon/(2|M|) \). By Lemma 14.24, we can make \( |f(x)| \) less than \( 1 + |L| \). Thus, we make \( |g(x) - M| < \epsilon/(2(1 + |L|)) \). Now, let’s put all of the pieces together.

**Theorem 14.25**

If \( \lim_{x \to a} f(x) = L \) and \( \lim_{x \to a} g(x) = M \), then \( \lim_{x \to a} f(x) \cdot g(x) = LM \).

**Proof**

Let \( \epsilon > 0 \) be given. By Lemma 14.24, there exists \( \delta_1 > 0 \) such that if \( 0 < |x - a| < \delta_1 \), then \( |f(x)| < 1 + |L| \). Since \( \lim_{x \to a} g(x) = M \), there exists \( \delta_2 > 0 \) such that if \( 0 < |x - a| < \delta_2 \), then \( |g(x) - M| < \epsilon/(2(1 + |L|)) \). We consider two cases.

**Case 1.** \( M = 0 \). Choose \( \delta = \min(\delta_1, \delta_2) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Then

\[ |f(x) \cdot g(x) - LM| = |f(x) \cdot g(x) - f(x) \cdot M + f(x) \cdot M - LM| \]
\[ = |f(x)(g(x) - M) + (f(x) - L)M| \]
\[ \leq |f(x)||g(x) - M| + |f(x) - L||M| \]
\[ < (1 + |L|)\epsilon/(2(1 + |L|)) + 0 = \epsilon/2 < \epsilon. \]

**Case 2.** \( M \neq 0 \). Since \( \lim_{x \to a} f(x) = L \), there exists \( \delta_3 > 0 \) such that if \( 0 < |x - a| < \delta_3 \), then \( |f(x) - L| < \epsilon/(2|M|) \). In this case, we choose \( \delta = \min(\delta_1, \delta_2, \delta_3) \). Now let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Then

\[ |f(x) \cdot g(x) - LM| = |f(x) \cdot g(x) - f(x) \cdot M + f(x) \cdot M - LM| \]
\[ = |f(x)(g(x) - M) + (f(x) - L)M| \]
\[ \leq |f(x)||g(x) - M| + |f(x) - L||M| \]
\[ < (1 + |L|)\epsilon/(2(1 + |L|)) + (\epsilon/(2|M|))|M| \]
\[ = \epsilon/2 + \epsilon/2 = \epsilon. \]

Next, we consider the limit of the quotient of two functions. As before, let \( \lim_{x \to a} f(x) = L \) and \( \lim_{x \to a} g(x) = M \). Our goal is to show that \( \lim_{x \to a} \frac{f(x)}{g(x)} = \frac{L}{M} \). Of course, this is not true if \( M = 0 \); so we will need to assume that \( M \neq 0 \). Since \( \lim_{x \to a} g(x) = M \neq 0 \), it follows not only that \( g(x) \neq 0 \) in some deleted neighborhood of \( a \) but that there is a properly chosen deleted neighborhood of \( a \) on which \( 1/|g(x)| \) is bounded. This is accomplished in the following lemma.

**Lemma 14.26**

If \( \lim_{x \to a} g(x) = M \neq 0 \), then \( 1/|g(x)| < 2/|M| \) for all \( x \) in some deleted neighborhood of \( a \).
\textbf{Proof} \ Let \( \epsilon = |M|/2 \). Then there exists \( \delta > 0 \) such that if \( 0 < |x - a| < \delta \), then \( |g(x) - M| < |M|/2 \). Therefore,

\[ |M| = |M - g(x) + g(x)| \leq |M - g(x)| + |g(x)|. \]

Hence, \( |g(x)| \geq |M| - |M - g(x)| > |M| - |M|/2 = |M|/2 \). Thus, \( 1/|g(x)| < 2/|M| \). \( \square \)

\textbf{Theorem to Prove} \ If \( \lim_{x \to a} f(x) = L \) and \( \lim_{x \to a} g(x) = M \neq 0 \), then \( \lim_{x \to a} \frac{f(x)}{g(x)} = \frac{L}{M} \).

\textbf{PROOF STRATEGY} \ To prove that \( \lim_{x \to a} \frac{f(x)}{g(x)} = \frac{L}{M} \), we are required to show that \( \left| \frac{f(x)}{g(x)} - \frac{L}{M} \right| \) can be made arbitrarily small. Observe that

\[ \left| \frac{f(x)}{g(x)} - \frac{L}{M} \right| = \left| \frac{f(x) \cdot M - L \cdot g(x)}{g(x) \cdot M} \right| = \left| \frac{f(x) \cdot M - LM + LM - L \cdot g(x)}{g(x) \cdot M} \right| \]

\[ = \left| \frac{(f(x) - L)M + LM - g(x)}{g(x) \cdot M} \right| \leq \frac{|f(x) - L||M| + |L||M - g(x)|}{|g(x)||M|} \]

\[ \leq \frac{|f(x) - L|}{|g(x)||M|} + \frac{|L||M - g(x)|}{|g(x)||M|}. \]

Thus, to show that \( \left| \frac{f(x)}{g(x)} - \frac{L}{M} \right| \) can be made less than \( \epsilon \) for any given positive number \( \epsilon \), it is sufficient to show that each of \( \frac{|f(x) - L|}{|g(x)||M|} \) and \( \frac{|L||M - g(x)|}{|g(x)||M|} \) can be made less than \( \epsilon/2 \). With the aid of Lemma 14.26, we now have

\[ \left| \frac{f(x)}{g(x)} - \frac{L}{M} \right| \leq \frac{|f(x) - L|}{|g(x)||M|} + \frac{|L||M - g(x)|}{|g(x)||M|} \]

\[ < |f(x) - L| \cdot \frac{2}{|M|} + |L||M - g(x)| \cdot \frac{2}{|M|}. \]

This suggests how small we must make \( |f(x) - L| \) and \( |g(x) - M| = |M - g(x)| \) to accomplish our goal. \( \diamond \)

\textbf{Theorem 14.27} \ If \( \lim_{x \to a} f(x) = L \) and \( \lim_{x \to a} g(x) = M \neq 0 \), then \( \lim_{x \to a} \frac{f(x)}{g(x)} = \frac{L}{M} \).

\textbf{Proof} \ Let \( \epsilon > 0 \) be given. By Lemma 14.26, there exists \( \delta_1 > 0 \) such that if \( 0 < |x - a| < \delta_1 \), then \( 1/|g(x)| < 2/|M| \). Since \( \lim_{x \to a} f(x) = L \), there exists \( \delta_2 > 0 \) such that if \( 0 < |x - a| < \delta_2 \), then \( |f(x) - L| < |M|\epsilon/4 \). We consider two cases.

\textit{Case 1.} \( L = 0 \). Define \( \delta = \min(\delta_1, \delta_2) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Then

\[ \left| \frac{f(x)}{g(x)} - \frac{L}{M} \right| \leq \frac{|f(x) - L|}{|g(x)||M|} + \frac{|L||M - g(x)|}{|g(x)||M|} \]

\[ < \frac{|M|\epsilon}{4} \cdot \frac{2}{|M|} + 0 = \frac{\epsilon}{2} < \epsilon. \]
Chapter 14  Proofs in Calculus

Case 2. \( L \neq 0 \). Since \( \lim_{x \to a} g(x) = M \), there exists \( \delta_3 > 0 \) such that if \( 0 < |x - a| < \delta_3 \), then \( |g(x) - M| < |M|^2 \epsilon / (4 |L|) \). In this case, define \( \delta = \min(\delta_1, \delta_2, \delta_3) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Then

\[
\left| \frac{f(x) - L}{g(x)} \right| \leq \frac{|f(x) - L|}{|g(x)|} + \frac{|L||M - g(x)|}{|g(x)||M|} < \frac{|M|\epsilon}{4} + \frac{2|L|}{|M|} \frac{|M|^2 \epsilon}{|L|} = \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon.
\]

Now, with the aid of Theorems 14.23, 14.25, 14.27 and a few other general results, it is possible to give simpler arguments for some of the limits we have discussed. First, we present some additional results, beginning with an observation concerning constant functions and followed by limits of polynomial functions defined by \( f(x) = x^n \) for some \( n \in \mathbb{N} \).

Theorem 14.28  Let \( a, c \in \mathbb{R} \). If \( f(x) = c \) for all \( x \in \mathbb{R} \), then \( \lim_{x \to a} f(x) = c \).

Proof  Let \( \epsilon > 0 \) be given and choose \( \delta \) to be any positive number. Let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Since \( f(x) = c \) for all \( x \in \mathbb{R} \), it follows that \( |f(x) - c| = |c - c| = 0 < \epsilon \).

Theorem 14.29  Let \( f(x) = x \) for all \( x \in \mathbb{R} \). For each \( a \in \mathbb{R} \), \( \lim_{x \to a} f(x) = a \).

Proof  Let \( \epsilon > 0 \) be given and choose \( \delta = \epsilon \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Then \( |f(x) - a| = |x - a| < \delta = \epsilon \).

We now extend the result in Theorem 14.29.

Theorem 14.30  Let \( n \in \mathbb{N} \) and let \( f(x) = x^n \) for all \( x \in \mathbb{R} \). Then for each \( a \in \mathbb{R} \), \( \lim_{x \to a} f(x) = a^n \).

Proof  We proceed by induction. The statement is true for \( n = 1 \) since if \( f(x) = x \), then \( \lim_{x \to a} f(x) = a \) by Theorem 14.29. Assume that \( \lim_{x \to a} x^k = a^k \), where \( k \in \mathbb{N} \). We show that \( \lim_{x \to a} x^{k+1} = a^{k+1} \). Observe that \( x^{k+1} = \lim_{x \to a} (x^k \cdot x) \). By Theorems 14.25 and 14.29 and the induction hypothesis,

\[
\lim_{x \to a} x^{k+1} = \lim_{x \to a} (x^k \cdot x) = (\lim_{x \to a} x^k) (\lim_{x \to a} x) = (a^k)(a) = a^{k+1}.
\]

By the Principle of Mathematical Induction, \( \lim_{x \to a} x^n = a^n \) for every \( n \in \mathbb{N} \).

It is possible to prove the following theorem by induction as well. We leave its proof as an exercise (Exercise 14.32).

Theorem 14.31  Let \( f_1, f_2, \ldots, f_n \) be functions \((n \in \mathbb{N})\) such that \( \lim_{x \to a} f_i(x) = L_i \) for \( 1 \leq i \leq n \). Then

\[
\lim_{x \to a} (f_1(x) + f_2(x) + \cdots + f_n(x)) = L_1 + L_2 + \cdots + L_n.
\]
Section 14.4 Exercises

With the results we have now presented, it is possible to prove that if \( p(x) = c_nx^n + \cdots + c_1x + c_0 \) is a polynomial, then

\[
\lim_{x \to a} p(x) = c_n a^n + \cdots + c_1 a + c_0 = p(a).
\] (14.1)

For example, applying this to Result 14.13, we have

\[
\lim_{x \to 4} (3x - 7) = 3 \cdot 4 - 7.
\]

Similarly, Result 14.14 can be established. Result 14.15 cannot be established directly since \( \lim_{x \to \frac{3}{2}} (2x - 3) = 0 \). Applying what we now know to Result 14.16, we have \( \lim_{x \to 3} x^2 = 3^2 = 9 \) and in Result 14.17,

\[
\lim_{x \to 2} (x^5 - 2x^3 - 3x - 7) = 2^5 - 2 \cdot 2^3 - 3 \cdot 2 - 7 = 3.
\]

Also, if \( r \) is a rational function, that is, if \( r(x) = \frac{p(x)}{q(x)} \) of two polynomials \( p(x) \) and \( q(x) \) such that \( q(a) \neq 0 \) for \( a \in \mathbb{R} \), then by Theorem 14.27,

\[
\lim_{x \to a} r(x) = \lim_{x \to a} \frac{p(x)}{q(x)} = \frac{\lim_{x \to a} p(x)}{\lim_{x \to a} q(x)} = \frac{p(a)}{q(a)} = r(a).
\] (14.2)

So, in Result 14.18, we have

\[
\lim_{x \to 1} \frac{x^2 + 1}{x^2 + 4} = \frac{1^2 + 1}{1^2 + 4} = \frac{2}{5}.
\]

Although it is simpler and certainly less time-consuming to verify certain limits with the aid of these theorems, we should also know how to verify limits by the \( \epsilon - \delta \) definition.

SECTION 14.4 EXERCISES

14.31. Use limit theorems to determine the following:

(a) \( \lim_{x \to 1} (x^3 - 2x^2 - 5x + 8) \)
(b) \( \lim_{x \to 1} (4x + 7)(3x^2 - 2) \)
(c) \( \lim_{x \to 2} \frac{2x^2 + 1}{x + 1} \)

14.32. Use induction to prove Theorem 14.31: For every integer \( n \geq 2 \) and every \( n \) functions \( f_1, f_2, \ldots, f_n \) such that \( \lim_{x \to a} f_i(x) = L_i \) for \( 1 \leq i \leq n \),

\[
\lim_{x \to a} (f_1(x) + f_2(x) + \cdots + f_n(x)) = L_1 + L_2 + \cdots + L_n.
\]

14.33. Use Exercise 14.32 to prove that \( \lim_{x \to a} p(x) = p(a) \) for every polynomial \( p(x) = c_nx^n + c_{n-1}x^{n-1} + \cdots + c_1x + c_0 \).

14.34. Prove that if \( f_1, f_2, \ldots, f_n \) are any \( n \geq 2 \) functions such that \( \lim_{x \to a} f_i(x) = L_i \) for \( 1 \leq i \leq n \), then

\[
\lim_{x \to a} (f_1(x) \cdot f_2(x) \cdots f_n(x)) = L_1 \cdot L_2 \cdots L_n.
\]
392 Chapter 14 Proofs in Calculus

14.5 CONTINUITY

Once again, let \( f : X \to \mathbb{R} \) be a function, where \( X \subseteq \mathbb{R} \), and let \( a \) be a real number such that \( f \) is defined in some deleted neighborhood of \( a \). Recall that \( \lim_{x \to a} f(x) = L \) if for every \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that if \( x \in (a - \delta, a + \delta) \) and \( x \neq a \), then \( |f(x) - L| < \varepsilon \). If \( f \) is defined at \( a \) and \( f(a) = L \), then \( f \) is said to be continuous at \( a \). That is, \( f \) is continuous at \( a \) if \( \lim_{x \to a} f(x) = f(a) \). Therefore, a function \( f \) is continuous at \( a \) if for every \( \varepsilon > 0 \), there exists \( \delta > 0 \) such that if \( |x - a| < \delta \), then \( |f(x) - f(a)| < \varepsilon \). (Notice that in this instance, \( 0 < |x - a| < \delta \) is being replaced by \( |x - a| < \delta \).) Thus, for \( f \) to be continuous at \( a \), three conditions must be satisfied:

(1) \( f \) is defined at \( a \); 
(2) \( \lim_{x \to a} f(x) \) exists; 
(3) \( \lim_{x \to a} f(x) = f(a) \).

We now illustrate this.

**Example 14.32** A function \( f \) is defined by \( f(x) = (x^2 - 3x + 2)/(x^2 - 1) \) for all \( x \in \mathbb{R} - \{-1, 1\} \). Is \( f \) continuous at 1 under any of the following circumstances: (a) \( f \) is not defined at 1; (b) \( f(1) = 0 \); (c) \( f(1) = -1/2 \)?

**Solution** For \( f \) to be continuous at 1, the function \( f \) must be defined at 1. So, we can answer question (a) immediately. The answer is no. In order to answer questions (b) and (c), we must first determine whether \( \lim_{x \to 1} f(x) \) exists. Observe that

\[
 f(x) = \frac{x^2 - 3x + 2}{x^2 - 1} = \frac{(x-1)(x-2)}{(x-1)(x+1)} = \frac{x-2}{x+1}
\]

since \( x \neq 1 \). Because \( f(x) = \frac{x-2}{x+1} \) is a rational function, we can apply (14, 2) to obtain

\[
 \lim_{x \to 1} \frac{x-2}{x+1} = \lim_{x \to 1} \frac{x-2}{x+1} = \frac{-1}{2} = -\frac{1}{2}.
\]

Hence, if \( f(1) = -1/2 \), then \( f \) is continuous at 1. Therefore, the answer to question (b) is no and the answer to (c) is yes.

For additional practice, we present an \( \varepsilon - \delta \) proof that \( \lim_{x \to 1} \frac{x^2 - 3x + 2}{x^2 - 1} = -\frac{1}{2} \).

**Result to Prove** \( \lim_{x \to 1} \frac{x^2 - 3x + 2}{x^2 - 1} = -\frac{1}{2} \).

**PROOF STRATEGY** Observe that

\[
 \left| \frac{x^2 - 3x + 2}{x^2 - 1} - \left( -\frac{1}{2} \right) \right| = \left| \frac{(x-1)(x-2)}{(x-1)(x+1)} + \frac{1}{2} \right| = \left| \frac{x-2}{x+1} + \frac{1}{2} \right| = \left| \frac{2(x-2) + (x+1)}{2(x+1)} \right| = \frac{3x - 3}{2(x+1)} = \frac{3}{2} \cdot \frac{|x-1|}{|x+1|}.
\]
If $|x - 1| < 1$, then $0 < x < 2$ and $|x + 1| > 1$, so $1/|x + 1| < 1$. We are now prepared to prove that $\lim_{x \to 1} f(x) = -1/2$. ♦

**Result 14.33**

$$\lim_{x \to 1} \frac{x^2 - 3x + 2}{x^2 - 1} = -\frac{1}{2}.$$  

**Proof**

Let $\epsilon > 0$ and choose $\delta = \min(1, 2\epsilon/3)$. Let $x \in \mathbb{R}$ such that $|x - 1| < \delta$. Since $|x - 1| < 1$, it follows that $0 < x < 2$. So, $|x + 1| > 1$ and $1/|x + 1| < 1$. Hence,

$$\left| x^2 - 3x + 2 - \frac{(x - 1)(x - 2)}{(x - 1)(x + 1)} - \frac{1}{2} \right| = \left| \frac{(x - 1)(x - 2) + 1}{(x - 1)(x + 1)} + 1 \right| = \left| \frac{(x - 2) + 1}{(x + 1)} + 1 \right|$$

$$= \left| \frac{3x - 3}{2(x + 1)} \right| = \frac{3|x - 1|}{2|x + 1|} < \frac{3}{2} \cdot \frac{2\epsilon}{3} = \epsilon.$$

Indeed, (14.2) states that if a rational function $r$ is defined by $r(x) = p(x)/q(x)$, where $p(x)$ and $q(x)$ are polynomials such that $q(a) \neq 0$, then $r$ is continuous at $a$. Also, (14.1) implies that if $p$ is a polynomial function defined by $p(x) = c_nx^n + c_{n-1}x^{n-1} + \cdots + c_1x + c_0$, then $p$ is continuous at every real number $a$.

We now present some examples concerning continuity for functions that are neither polynomials nor rational functions.

**Result to Prove**

The function $f$ defined by $f(x) = \sqrt{x}$ for $x \geq 0$ is continuous at 4.

**Proof Strategy**

Because $f(4) = 2$, it suffices to show that $\lim_{x \to 4} \sqrt{x} = 2$. Thus, $|f(x) - L| = |\sqrt{x} - 2|$. To work $x - 4$ into the expression $\sqrt{x} - 2$, we multiply $\sqrt{x} - 2$ by $(\sqrt{x} + 2)/(\sqrt{x} + 2)$, obtaining

$$\left| \sqrt{x} - 2 \right| = \left| \frac{(\sqrt{x} - 2)(\sqrt{x} + 2)}{\sqrt{x} + 2} \right| = \frac{|x - 4|}{\sqrt{x} + 2}.$$  

First we require that $\delta \leq 1$, that is, $|x - 4| < 1$, so $3 < x < 5$. Since $\sqrt{x} + 2 > 3$, it follows that $1/(\sqrt{x} + 2) < 1/3$. Hence,

$$\left| \sqrt{x} - 2 \right| = \frac{|x - 4|}{\sqrt{x} + 2} < \frac{|x - 4|}{3}.$$  

This suggests an appropriate choice for $\delta$. ♦

**Result 14.34**

The function $f$ defined by $f(x) = \sqrt{x}$ for $x \geq 0$ is continuous at 4.

**Proof**

Let $\epsilon > 0$ be given and choose $\delta = \min(1, 3\epsilon)$. Let $x \in \mathbb{R}$ such that $|x - 4| < \delta$. Since $|x - 4| < 1$, it follows that $3 < x < 5$ and so $\sqrt{x} + 2 > 3$. Therefore, $1/(\sqrt{x} + 2) < 1/3$. Hence,

$$\left| \sqrt{x} - 2 \right| = \left| \frac{(\sqrt{x} - 2)(\sqrt{x} + 2)}{\sqrt{x} + 2} \right| = \frac{|x - 4|}{\sqrt{x} + 2} < \frac{1}{3}(3\epsilon) = \epsilon.$$  

Figure 14.5 gives the graph of the ceiling function $f : \mathbb{R} \to \mathbb{Z}$ defined by $f(x) = \lceil x \rceil$. This function is not continuous at any integer but is continuous at all other
real numbers. We verify the first of these remarks and leave the proof of the second remark as an exercise (Exercise 14.37).

![Graph of the ceiling function](image)

**Figure 14.5** The graph of the ceiling function $f(x) = \lceil x \rceil$

**Result 14.35** The ceiling function $f : \mathbb{R} \to \mathbb{Z}$ defined by $f(x) = \lceil x \rceil$ is not continuous at any integer.

**Proof** Assume, to the contrary, that there is some integer $k$ such that $f$ is continuous at $k$. Therefore, $\lim_{x \to k} f(x) = f(k) = \lceil k \rceil = k$. Hence, for $\epsilon = 1$, there exists $\delta > 0$ such that if $|x - k| < \delta$, then $|f(x) - f(k)| = |f(x) - k| < \epsilon = 1$. Let $\delta_1 = \min(\delta, 1)$ and let $x_1 \in (k, k + \delta_1)$. Thus, $k < x_1 < k + \delta$ and $k < x_1 < k + 1$. Hence, $f(x_1) = \lceil x_1 \rceil = k + 1$ and $|f(x_1) - k| = |(k + 1) - k| = 1 < 1$, a contradiction. \[\blacksquare\]

**SECTION 14.5 EXERCISES**

14.35. The function $f : \mathbb{R} \setminus \{0, 2\} \to \mathbb{R}$ is defined by $f(x) = \frac{x^2 + 1}{x - 2}$. Use limit theorems to determine whether $f$ can be defined at 2 such that $f$ is continuous at 2.

14.36. The function $f$ defined by $f(x) = \frac{x^3 + x}{x^2 - 1}$ is not defined at 3. Is it possible to define $f$ at 3 such that $f$ is continuous there? Verify your answer with an $\epsilon - \delta$ proof.

14.37. Let $f : \mathbb{R} \to \mathbb{Z}$ be the ceiling function defined by $f(x) = \lceil x \rceil$. Give an $\epsilon - \delta$ proof that if $a$ is a real number that is not an integer, then $f$ is continuous at $a$.

14.38. Show that Exercise 14.33 implies that every polynomial is continuous at every real number.

14.39. Prove that the function $f : [1, \infty) \to [0, \infty)$ defined by $f(x) = \sqrt{x - 1}$ is continuous at $x = 10$.

14.40. (a) Let $f : \mathbb{R} \to \mathbb{R}$ be defined by

$$f(x) = \begin{cases} 0 & \text{if } x \text{ is rational} \\ 1 & \text{if } x \text{ is irrational.} \end{cases}$$

In particular, $f(0) = 0$. Prove or disprove: $f$ is continuous at $x = 0$.

(b) The problem in (a) should suggest another problem to you. State and solve such a problem.
14.6 DIFFERENTIABILITY

We have discussed the existence and nonexistence of limits $\lim_{x \to a} f(x)$ for functions $f : X \to \mathbb{R}$ with $X \subseteq \mathbb{R}$, where $f$ is defined in a deleted neighborhood of the real number $a$ and, in the case of continuity at $a$, investigated whether $\lim_{x \to a} f(x) = f(a)$ if $f$ is defined in a neighborhood of $a$. If $f$ is defined in a neighborhood of $a$, then there is an important limit that concerns the ratio of the differences $f(x) - f(a)$ and $x - a$.

A function $f : X \to \mathbb{R}$, where $X \subseteq \mathbb{R}$, that is defined in a neighborhood of a real number $a$ is said to be differentiable at $a$ if $\lim_{x \to a} \frac{f(x) - f(a)}{x - a}$ exists. This limit is called the derivative of $f$ at $a$ and is denoted by $f'(a)$. Therefore,

$$f'(a) = \lim_{x \to a} \frac{f(x) - f(a)}{x - a}.$$ 

You probably already know that $f'(a)$ is the slope of the tangent line to the graph of $y = f(x)$ at the point $(a, f(a))$. Indeed, if $f'(a) = m$, then the equation of this line is $y - f(a) = m(x - a)$. See Figure 14.6.

We illustrate derivatives with an example.

![Figure 14.6 Derivatives and slopes of tangent lines](image)

**Example 14.36** Show that the function $f$ defined by $f(x) = 1/x^2$ for $x \neq 0$ is differentiable at 1 and determine $f'(1)$.

**Solution** Thus, we need to show that $\lim_{x \to 1} \frac{f(x) - f(1)}{x - 1} = \lim_{x \to 1} \frac{1 - x^2}{x(x - 1)}$ exists. In a deleted neighborhood of 1,

$$\frac{1}{x^2} - 1 = \frac{1 - x^2}{x(x - 1)} = \frac{1}{x^2} - 1 = \frac{(1 - x)(1 + x)}{x^2(x - 1)} = -\frac{1 + x}{x^2}. \quad (14.3)$$
Since \( \frac{1 + x}{x^2} \) is a rational function, we can once again use (14.2) to see that
\[
\lim_{x \to 1} \frac{1 + x}{x^2} = \lim_{x \to 1} (1 + x) \frac{1}{x^2} = \frac{2}{1} = -2
\]
and so \( f'(1) = -2 \).

We also present an \( \epsilon - \delta \) proof of the limit encountered in Example 14.36.

**Proof Strategy**

For a given \( \epsilon > 0 \), we are required to find \( \delta > 0 \) such that if \( x \in \mathbb{R} \) with \( 0 < |x - 1| < \delta \), then \( \left| \frac{1}{x} - 1 \right| < \epsilon \). Observe that
\[
\left| \frac{1}{x} - 1 \right| = \left| -\frac{1 + x}{x^2} \right| = \left| \frac{2x - 1}{x^2} \right| = \left| \frac{|x - 1| |2x + 1|}{x^2} \right|.
\]
If we restrict \( \delta \) so that \( \delta < 1/2 \), then \( |x - 1| < 1/2 \) and so \( 1 < x < 3/2 \). Since \( x > 1/2 \), it follows that \( x^2 > 1/4 \) and \( 1/x^2 < 4 \). Thus, \( ||x - 1||2x + 1|/x^2 < 16|x - 1| \). This shows us how to select \( \delta \). We now prove that \( f'(1) = -2 \).

**Result 14.37**

Let \( f \) be the function defined by \( f(x) = 1/x^2 \) for \( x \neq 0 \). Then \( f'(1) = -2 \).

**Proof**

Let \( \epsilon > 0 \) be given and choose \( \delta = \min(1/2, \epsilon/16) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 1| < \delta \). Since \( |x - 1| < 1/2 \), it follows that \( 1/2 < x < 3/2 \). Thus, \( x^2 > 1/4 \) and so \( 1/x^2 < 4 \). Also, \( |2x + 1| < 4 \). Since \( |x - 1| < \epsilon/16 \), it follows that
\[
\left| \frac{1}{x} - 1 \right| = \left| -\frac{1 + x}{x^2} \right| = \left| -\frac{1 + x}{x^2} \right| = \left| = \left| \frac{2x^2 - x - 1}{x^2} \right| = \left| \frac{|x - 1| |2x + 1|}{x^2} \right| = \left| \frac{|x - 1| |2x^2 - x - 1|}{x^2} \right| = \left| \frac{2x + 1}{x^2} \cdot |x - 1| < 4 \cdot 4 \cdot \frac{\epsilon}{16} = \epsilon \right.
\]
From Result 14.37, it now follows that the slope of the tangent line to the graph of \( y = 1/x^2 \) at the point \((1, 1)\) is \( -2 \) and, consequently, that the equation of this tangent line is \( y = 1 = -2(x - 1) \). Differentiability of a function at some number \( a \) implies continuity at \( a \) as well, as we now show.

**Theorem 14.38**

If a function \( f \) is differentiable at a real number \( a \), then \( f \) is continuous at \( a \).

**Proof**

Since \( f \) is differentiable at \( a \), it follows that \( \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \) exists and equals the real number \( f'(a) \). To show that \( f \) is continuous at \( a \), we need to show that \( \lim_{x \to a} f(x) = f(a) \). We write \( f(x) \) as
\[
f(x) = \frac{f(x) - f(a)}{x - a} (x - a) + f(a).
\]
Now, using properties of limits, we have

\[
\lim_{x \to a} f(x) = \left[ \lim_{x \to a} \frac{f(x) - f(a)}{x - a} \right] \lim_{x \to a} (x - a) + \lim_{x \to a} f(a) = f'(a) \cdot 0 + f(a) = f(a).
\]

The converse of Theorem 14.38 is not true. For example, the functions \(f\) and \(g\) defined by \(f(x) = |x|\) and \(g(x) = \sqrt{x}\) are continuous at 0 but neither is differentiable at 0. That \(f\) is not differentiable at 0 is actually established in Result 14.22.

SECTION 14.6 EXERCISES

14.41. The function \(f : \mathbb{R} \to \mathbb{R}\) is defined by \(f(x) = x^2\). Determine \(f'(3)\) and verify that your answer is correct with an \(\epsilon - \delta\) proof.

14.42. The function \(f : \mathbb{R} \to \mathbb{R}\) is defined by \(f(x) = \frac{1}{x^2}\). Determine \(f'(1)\) and verify that your answer is correct with an \(\epsilon - \delta\) proof.

14.43. The function \(f : \mathbb{R} \to \mathbb{R}\) is defined by \(f(x) = x^3\). Determine \(f'(a)\) for \(a \in \mathbb{R}^+\) and verify that your answer is correct with an \(\epsilon - \delta\) proof.

14.44. The function \(f : \mathbb{R} \to \mathbb{R}\) is defined by

\[
f(x) = \begin{cases} 
  x^2 \sin \frac{1}{x} & \text{if } x \neq 0 \\
  0 & \text{if } x = 0.
\end{cases}
\]

Determine \(f'(0)\) and verify that your answer is correct with an \(\epsilon - \delta\) proof.

Chapter 14 Supplemental Exercises

14.45. Prove that the sequence \(\left\{ \frac{n+1}{3n-1} \right\}\) converges to \(\frac{1}{3}\).

14.46. Prove that \(\lim_{n \to \infty} \frac{2n^2}{4n^2 + 1} = \frac{1}{2}\).

14.47. Prove that the sequence \(\{ 1 + (-2)^n \}\) diverges.

14.48. Prove that \(\lim_{n \to \infty} (\sqrt{n^2 + 1} - n) = 0\).

14.49. Prove that the sequence \(\{ (-1)^{n+1} \frac{n+1}{2n+1} \}\) diverges.

14.50. Prove that \(\lim_{n \to \infty} \frac{n}{3n + 1} = \frac{1}{3}\).

14.51. Let \(a, c_0, c_1 \in \mathbb{R}\) such that \(c_1 \neq 0\). Give an \(\epsilon - \delta\) proof that \(\lim_{x \to a} (c_1x + c_0) = c_1a + c_0\).

14.52. Evaluate the proposed solution of the following problem.

**Problem** The function \(f : \mathbb{R} \to \mathbb{R}\) is defined by

\[
f(x) = \begin{cases} 
  \frac{x^2 - 4}{x^2 - 2} & \text{if } x \neq 2 \\
  2 & \text{if } x = 2.
\end{cases}
\]
Determine whether \( \lim_{x \to 2} f(x) \) exists.

**Solution**

\[
\lim_{x \to 2} f(x) = \lim_{x \to 2} \frac{x^2 - 4}{x - 2} = \lim_{x \to 2} \frac{(x - 2)(x + 2)}{x - 2} = \lim_{x \to 2} (x + 2) = 4.
\]

However, since \( \lim_{x \to 2} f(x) = 4 \neq f(2) = \frac{2}{3} \), the limit does not exist.

\[\blacklozenge\]

14.53. Evaluate the proposed proof of the following result.

**Result**

The sequence \( \left\{ \frac{2n}{3n + 5} \right\} \) converges to \( \frac{2}{3} \).

**Proof**

Let \( \epsilon > 0 \) be given. Choose \( N = \left\lceil \frac{10}{9\epsilon} - \frac{5}{3} \right\rceil \) and let \( n > N \). Then

\[
n > \frac{10}{9\epsilon} - \frac{5}{3} \quad \text{Hence,} \quad 9n > \frac{10}{\epsilon} - 15 \quad \text{and} \quad 9n + 15 > \frac{10}{\epsilon}.
\]

Therefore,

\[
\frac{9n + 15}{10} > \frac{1}{\epsilon} \quad \text{and} \quad \frac{10}{9n + 15} < \epsilon.
\]

Now

\[
\left| \frac{2n}{3n + 5} - \frac{2}{3} \right| = \left| \frac{6n - 2(3n + 5)}{3(3n + 5)} \right| = \frac{|-10|}{9n + 15} = \frac{10}{9n + 15} < \epsilon.
\]

\[\blacksquare\]

14.54. Evaluate the proposed proof of the following result.

**Result**

\( \lim_{x \to 1} \frac{1}{2x - 3} = -1 \).

**Proof**

Let \( \epsilon > 0 \) and choose \( \delta = \min(1, \frac{2\epsilon}{7}) \). Let \( 0 < |x - 1| < \delta = \min(1, \frac{2\epsilon}{7}) \).

Since \( |x - 1| < 1 \), it follows that \( 0 < x < 2 \) and so

\[
|2x - 3| = |2x| + |3| = 2|x| + 3 < 2\cdot 4 + 3 = 7.
\]

Since \( |x - 1| < 7\epsilon/2 \), we have

\[
\left| \frac{1}{2x - 3} + 1 \right| = \frac{|2x - 2|}{|2x - 3|} = \frac{2|x - 1|}{|2x - 3|} < \frac{2\cdot 7\epsilon}{2} = \epsilon.
\]

\[\blacksquare\]

14.55. Let \( \{a_n\} \), \( \{b_n\} \) and \( \{c_n\} \) be sequences of real numbers such that \( a_n \leq b_n \leq c_n \) for every positive integer \( n \) and \( \lim_{n \to \infty} a_n = \lim_{n \to \infty} c_n = L \).

(a) Prove that \( \lim_{n \to \infty} (c_n - a_n) = 0 \).

(b) Prove that \( \lim_{n \to \infty} b_n = L \).

14.56. In Chapter 11 it was shown that the set \( \mathbb{Q} \) of rational numbers is denumerable and consequently can be expressed as \( \mathbb{Q} = \{q_1, q_2, q_3, \ldots\} \). A function \( f : \mathbb{R} \to \mathbb{R} \) is defined by

\[
f(x) = \begin{cases} \frac{1}{n} & \text{if } x = q_n \text{ (} n = 1, 2, 3, \ldots \) } \\
0 & \text{if } x \text{ is irrational.}
\end{cases}
\]

(a) Prove that \( f \) is continuous at each irrational number.

(b) Prove that \( f \) is not continuous at any rational number.

(c) If the function \( f \) were defined as above except that \( f(0) = 0 \), then prove that \( f \) would be continuous at 0.
14.57. Consider the sequence \( \frac{1}{n} + (-1)^n \frac{1}{n} \).

(a) What are the first eight terms of this sequence?
(b) Does this sequence converge or diverge? Verify your answer.

14.58. Evaluate the proposed proof of the following.

**Result** The sequence \( \{-1\}^n n \} \) diverges.

**Proof** Assume, to the contrary, that \( \{-1\}^n n \} \) converges, say 
\[ \lim_{n \to \infty} (-1)^{n+1} n = L. \]
Let \( \epsilon = 1 \). Then there exists a positive integer \( N \) such that if 
\[ n > N, \text{ then } |(-1)^{n+1} n - L| < \epsilon = 1. \]
Hence,
\[ -1 < (-1)^{n+1} n - L < 1 \]
and so \( L - 1 < (-1)^{n+1} n < L + 1 \).

If \( n \geq 3 \) is odd, then \( L - 1 < n < L + 1 \) and so \( L > 2 \). If \( n \geq 2 \) is even, then 
\( L - 1 < -n < L + 1 \) and so \( L < -1 \), a contradiction.

14.59. Evaluate the proposed proof of the following.

**Result** The sequence \( \{2n + 1 \}^{3n + 2} \) converges to \( \frac{2}{3} \).

**Proof** Let \( \epsilon > 0 \) be given. Choose \( N = \left\lceil \frac{1}{9\epsilon} - \frac{2}{3} \right\rceil \) and let \( n \) be any integer such that 
\[ n > N. \text{ Since } n > N, \text{ it follows that } n > \frac{1}{9\epsilon} - \frac{2}{3} \] and so \( 9n > \frac{1}{\epsilon} - 6 \). Hence,
\[ \frac{1}{\epsilon} < 9n + 6 \text{ and so } \frac{1}{9n + 6} < \epsilon. \]
Now, \[ \left| \frac{2n + 1}{3n + 2} - \frac{2}{3} \right| = \left| \frac{-1}{9n + 6} \right| = \frac{1}{9n + 6} < \epsilon. \]

14.60. Evaluate the proposed proof of the following.

**Result** The sequence \( \{1 / e^n \} \) converges to 0.

**Proof** Let \( \epsilon > 0 \) be given. Choose \( N = \left\lceil \ln \left( \frac{1}{\epsilon} \right) \right\rceil \) and let \( n \) be any integer such that 
\[ n > N. \text{ Then } n > \ln \left( \frac{1}{\epsilon} \right) \] and so \( e^n > \frac{1}{\epsilon} \). Thus, \( \frac{1}{e^n} < \epsilon. \) Therefore,
\[ \left| \frac{1}{e^n} - 0 \right| = \frac{1}{e^n} < \epsilon. \]

14.61. Prove that if the series \( \sum_{k=1}^{\infty} a_k \) converges to \( L \) and \( \sum_{k=1}^{\infty} b_k \) converges to \( M \), then 
\( \sum_{k=1}^{\infty} (a_k + b_k) \) converges to \( L + M \).

14.62. Give an \( \epsilon - \delta \) proof that \( \lim_{x \to 1} \frac{x^2 + 1}{x^3 + 1} = 1. \)

14.63. Give an \( \epsilon - \delta \) proof that \( \lim_{x \to 3} \frac{2x}{x - 2} = 6. \)

14.64. Give an \( \epsilon - \delta \) proof that \( \lim_{x \to -1} \frac{x^2 - 1}{|x| - 1} = 2. \)

14.65. The function \( f : \mathbb{R} \to \mathbb{R} \) is defined by
\[ f(x) = \begin{cases} x^2 & \text{if } x \in \mathbb{Q} \\ 0 & \text{if } x \in \mathbb{R} - \mathbb{Q} \end{cases} \]

Prove that \( f'(0) = 0. \)
15 Proofs in Group Theory

Many of the proofs that we have seen involve familiar sets of numbers (especially integers, rational numbers and real numbers). Also, most of the theorems and examples that we have encountered concern additive properties of these numbers or multiplicative properties (or both). Many important properties of integers (or of rational or real numbers) come not from the integers themselves, but from the addition and multiplication of integers. This suggests a basic question in mathematics: For a given nonempty set \( S \), can we describe other, less familiar methods of associating an element of \( S \) with each pair of elements of \( S \) in such a way that some interesting properties occur? The mathematical subject that deals with questions such as these is abstract algebra (also called modern algebra or simply algebra). In this chapter we will look at one of the most familiar concepts in abstract algebra. First, however, we must have a clear understanding of what we mean by associating an element of a given set with each pair of elements of that set and what properties may be considered interesting.

15.1 BINARY OPERATIONS

When we add two integers \( a \) and \( b \), we perform an operation (namely addition) to produce an integer that we denote by \( a + b \). Similarly, when we multiply these two integers, we perform another operation (namely multiplication) to produce an integer that we denote by \( a \cdot b \) (or \( ab \)). Both of these operations do something very similar. Each takes a pair \( a, b \) of integers, actually an ordered pair \( (a, b) \) of integers, and associates with this pair a unique integer. Therefore, these operations are actually functions, namely functions from \( \mathbb{Z} \times \mathbb{Z} \) to \( \mathbb{Z} \). These functions are examples of a concept called a binary operation.

By a binary operation \( * \) on a nonempty set \( S \), we mean a function from \( S \times S \) to \( S \), that is, \( * \) is a function that maps every ordered pair of elements of \( S \) to an element of \( S \). Thus, \( * : S \times S \rightarrow S \). In particular, if the ordered pair \( (a, b) \) in \( S \times S \) is mapped into the element \( c \) in \( S \) by a binary operation \( * \) (that is, \( c \) is the image of \( (a, b) \) under \( * \)), then we write \( c = a * b \) rather than the more awkward notation \( *((a, b)) = c \).

Consequently, addition \( + \) and multiplication \( \cdot \) are binary operations on \( \mathbb{Z} \). For example, under addition, the ordered pair \( (3, 5) \) is mapped into \( 3 + 5 = 8 \); while under
15.1 Binary Operations

...multiplication, (3, 5) is mapped into 3 \cdot 5 = 15. Subtraction is also a binary operation on \( \mathbb{Z} \) but it is not a binary operation on \( \mathbb{N} \) since, for example, subtraction maps the ordered pair (3, 5) into 3 – 5 = –2, which does not belong to \( \mathbb{N} \). Therefore, subtraction is not a function from \( \mathbb{N} \times \mathbb{N} \) to \( \mathbb{N} \) since it is not defined at (3, 5), as well as at many other ordered pairs of positive integers. Similarly, division is not a binary operation on \( \mathbb{Z} \) or on \( \mathbb{N} \) because it is not defined for many ordered pairs, including \((1, 0) \in \mathbb{Z} \times \mathbb{Z} \) and \((2, 3) \in \mathbb{N} \times \mathbb{N} \) because \(1/0 \notin \mathbb{Z} \) and \(2/3 \notin \mathbb{N} \). However, division is a binary operation on the set \( \mathbb{Q}^+ \) of positive rational numbers since the quotient of two positive rational numbers is once again a positive rational number.

Not only are addition and multiplication binary operations on \( \mathbb{Z} \), they are binary operations on \( \mathbb{Q} \) and \( \mathbb{R} \), as well as on \( \mathbb{R}^+ \) (the positive real numbers) and \( \mathbb{Q}^+ \). For the set \( \mathbb{R}^* \) of nonzero real numbers, multiplication is a binary operation but addition is not (since \( 1 + (-1) = 0 \notin \mathbb{R}^* \), for example).

If \(*\) is a binary operation on a set \( S \), then, by definition, \( a * b \in S \) for all \( a, b \in S \). If \( T \) is a nonempty subset of \( S \) and \( a, b \in T \), then certainly \( a * b \in S \); however, \( a * b \) need not belong to \( T \). A nonempty subset \( T \) of \( S \) is said to be closed under \(*\) if whenever, \( a, b \in T \), then \( a * b \in T \) as well. If \(*\) is a binary operation on \( S \), then certainly \( S \) is closed under \(*\). Although subtraction is a binary operation on \( \mathbb{Z} \), the subset \( \mathbb{N} \) of \( \mathbb{Z} \) is not closed under subtraction.

Among familiar sets with familiar binary operations are:

(a) the set \( \mathbb{Z}_n = \{[0], [1], \ldots, [n – 1]\} \) of the integers modulo \( n \geq 2 \) under addition \([a] + [b] = [a + b]\) and under multiplication \([a] \cdot [b] = [ab]\) (as defined in Chapter 9);

(b) the set \( M_2(\mathbb{R}) \) of all \( 2 \times 2 \) matrices over \( \mathbb{R} \) (that is, whose entries are real numbers) under matrix addition

\[
\begin{bmatrix} a & b \\ c & d \end{bmatrix} + \begin{bmatrix} e & f \\ g & h \end{bmatrix} = \begin{bmatrix} a + e & b + f \\ c + g & d + h \end{bmatrix}
\]

and under matrix multiplication

\[
\begin{bmatrix} a & b \\ c & d \end{bmatrix} \cdot \begin{bmatrix} e & f \\ g & h \end{bmatrix} = \begin{bmatrix} ae + bg & af + bh \\ ce + dg & cf + dh \end{bmatrix};
\]

(c) the set \( \mathcal{F}_\mathbb{R} = \mathbb{R}^\mathbb{R} \) of functions from \( \mathbb{R} \) to \( \mathbb{R} \) under function addition \((f + g)(x) = f(x) + g(x)\), under function multiplication \((f \cdot g)(x) = f(x) \cdot g(x)\) and under function composition \((f \circ g)(x) = f(g(x))\);

(d) the power set \( \mathcal{P}(A) \) of a set \( A \) under set union, under set intersection and under set difference.

For a more abstract example of a binary operation, let \( S = \{a, b, c\} \). A binary operation \(*\) on \( S \) is illustrated in the table in Figure 15.1 where then, \( a * a = b, a * b = c, a * c = a \), etc. Since every element in the table belongs to \( S \), it follows that \(*\) is indeed a binary operation on \( S \).

Although it may seem relatively clear that a binary operation is defined in each example given above, not all binary operations are so immediate.
402    Chapter 15    Proofs in Group Theory

\[ a \ast b = ab + 2a + 2b + 2, \]

where the operations indicated in \( ab + 2a + 2b + 2 \) are ordinary addition and multiplication in \( \mathbb{R} \). Then \( \ast \) is a binary operation on \( \mathbb{R} \setminus \{-2\} \).

\begin{proof}
We need to show that if \( a, b \in \mathbb{R} \setminus \{-2\} \), then \( a \ast b \in \mathbb{R} \setminus \{-2\} \). Assume, to the contrary, that there exists some pair \( x, y \in \mathbb{R} \setminus \{-2\} \) such that \( x \ast y \notin \mathbb{R} \setminus \{-2\} \). Thus, \( x \ast y = xy + 2x + 2y + 2 = -2 \). This equation is equivalent to \((x + 2)(y + 2) = 0\), so either \( x = -2 \) or \( y = -2 \), which is impossible since \( x, y \in \mathbb{R} \setminus \{-2\} \). Hence, \( \ast \) is a binary operation on \( \mathbb{R} \setminus \{-2\} \). \( \blacksquare \)

A nonempty set \( S \) with a binary operation \( \ast \) is often denoted by \((S, \ast)\). We refer to \((S, \ast)\) as an algebraic structure. There are certain properties that \((S, \ast)\) may possess that will be of special interest to us. In particular,

**G1** \((S, \ast)\) is associative if \( a \ast (b \ast c) = (a \ast b) \ast c \) for all \( a, b, c \in S \);

**G2** \((S, \ast)\) has an element \( e \), called an identity element (or simply an identity), if \( a \ast e = e \ast a = a \) for each \( a \in S \);

**G3** \((S, \ast)\) has an identity \( e \) and, for each element \( a \in S \), there is an element \( s \in S \), called an inverse for \( a \), such that \( a \ast s = s \ast a = e \);

**G4** \((S, \ast)\) is commutative if \( a \ast b = b \ast a \) for all \( a, b \in S \).

Two elements \( a, b \in S \) are said to commute if \( a \ast b = b \ast a \). If every two elements of \( S \) commute, then \((S, \ast)\) satisfies property G4. By property G2, an identity commutes with every element of \( S \); and by property G3, each element of \( S \) commutes with an inverse of this element (assuming, of course, that it has an inverse).

An algebraic structure \((S, \ast)\) may satisfy all, some or none of the properties G1–G4; however, \((S, \ast)\) cannot satisfy G3 without first satisfying G2. For elements \( a, b, c \in S \), the expression \( a \ast b \ast c \) is, strictly speaking, not defined. Since \( \ast \) is a binary operation, it is only defined for pairs of elements of \( S \). There are two standard interpretations of \( a \ast b \ast c \). Namely, does \( a \ast b \ast c \) mean \( a \ast (b \ast c) \) or does \( a \ast b \ast c \) mean \((a \ast b) \ast c \)? On the other hand, if \((S, \ast)\) satisfies property G1 (the associative property), then \( a \ast (b \ast c) = (a \ast b) \ast c \) and so either interpretation is acceptable in this case. For this reason, we often write \( a \ast b \ast c \) (without any parentheses). Ordinarily, however, we will continue to write \( a \ast (b \ast c) \) or \((a \ast b) \ast c \) to emphasize the importance of parentheses, even when \((S, \ast)\) satisfies the associative property.
Certainly \((\mathbb{Z}, +)\) satisfies properties G1 – G4, where 0 is an identity element and \(-n\) is an inverse for the integer \(n\). Moreover, \((\mathbb{R}, \cdot)\) satisfies properties G1, G2 and G4, where the integer 1 is an identity element. Turning to property G3, we see that every real number \(r\) has \(1/r\) as an inverse, except 0, which has no inverse since there is no real number \(s\) such that \(0 \cdot s = s \cdot 0 = 1\). Thus, \((\mathbb{R}, \cdot)\) does not satisfy G3. In the case of \((\mathbb{R}^+, \cdot)\), where recall, \(\mathbb{R}^+\) is the set of all nonzero real numbers, all four properties G1 – G4 are satisfied.

The algebraic structure \((\mathbb{Z}_n, +)\), \(n \geq 2\), also satisfies all of the properties G1 – G4, where \([0]\) is an identity and \([-a]\) is an inverse of \([a]\). On the other hand, \((\mathbb{Z}_n, \cdot)\) satisfies only G1, G2 and G4, where \([1]\) is an identity; however \((\mathbb{Z}_n, \cdot)\) does not satisfy G3 since, for example, there is no element \([s] \in \mathbb{Z}_n\) such that \([0][s] = [1]\) in \(\mathbb{Z}_n\) and so \([0]\) does not have an inverse.

The algebraic structure \((M_2(\mathbb{R}), +)\) satisfies all of the properties G1 – G4, where

\[
\begin{pmatrix}
0 & 0 \\
0 & 0
\end{pmatrix}
\]

is an identity and

\[
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix}
\]

\(d\) is an inverse of

\[
\begin{pmatrix}
a & b \\
c & d
\end{pmatrix}
\].

The algebraic structure \((M_2(\mathbb{R}), \cdot)\) only satisfies G1 and G2, where \(I = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}\) is an identity. For \(A = \begin{pmatrix} a & b \\ c & d \end{pmatrix}\) to have an inverse, the number \(ad - bc\) (the determinant of \(A\)) must be nonzero. Thus, \((M_2(\mathbb{R}), \cdot)\) does not satisfy G3. Also,

\[
\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \neq \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix}
\]

shows that \((M_2(\mathbb{R}), \cdot)\) does not satisfy property G4.

The algebraic structure \((\mathcal{S}, *)\) shown in Figure 15.1 is not associative since, for example, \(b \ast (b \ast c) = b \ast a = a\), while \((b \ast b) \ast c = c \ast c = b\) and so \(b \ast (b \ast c) \neq (b \ast b) \ast c\). Since \(\mathcal{S}\) contains no element \(e\) such that \(e \ast x = x \ast e = x\) for all \(x \in S\), it follows that \((\mathcal{S}, *)\) does not have an identity. Also, \(a \ast c \neq c \ast a\) since \(a \ast c = a\) and \(c \ast a = c\). Consequently, \((\mathcal{S}, \ast)\) has none of the properties G1 – G4.

Let’s look at another binary operation defined on \(S = \{a, b, c\}\).

**Example 15.2** A binary operation \(\ast\) is defined on the set \(S = \{a, b, c\}\) by \(x \ast y = x\) for all \(x, y \in S\). Determine which of the properties G1 – G4 are satisfied by \((S, \ast)\).

**Solution** Let \(x, y\) and \(z\) be any three elements of \(S\) (distinct or not). Then \(x \ast (y \ast z) = x \ast y = x\), while \((x \ast y) \ast z = x \ast z = x\). Thus, \((S, \ast)\) is associative. Now \((S, \ast)\) has no identity since for every element \(e \in S\), it follows that \(e \ast a = e \ast b = e\) and so it is impossible for \(e \ast a = a\) and \(e \ast b = b\). Since \((S, \ast)\) has no identity, the question of inverses does not apply here. Certainly, \((S, \ast)\) is not commutative since \(a \ast b = a\) while \(b \ast a = b\).

The verification of the associative law in Example 15.2 probably would have looked better had we written

\[x \ast (y \ast z) = x \ast y = x \ast z = (x \ast y) \ast z.\]

**Example 15.3** Let \(\mathbb{N}_0\) be the set of nonnegative integers and consider \((\mathbb{N}_0, \ast)\), where \(\ast\) is the binary operation defined by \(a \ast b = |a - b|\) for all \(a, b \in \mathbb{N}_0\). Determine which of the four properties G1 – G4 are satisfied by \((\mathbb{N}_0, \ast)\).
Chapter 15  Proofs in Group Theory

**Solution**
Since $1 \ast (2 \ast 3) = 1 \ast (2) = 1 \ast 1 = 0$ and $(1 \ast 2) \ast 3 = (1 \ast 3) = 1 \ast 2 = 1$, it follows that $(1 \ast 2) \ast 3 \neq 1 \ast (2 \ast 3)$ and so $(\mathbb{N}_0, \ast)$ is not associative. Let $a \in \mathbb{N}_0$. Then $a \ast 0 = 0 \ast a = |a| = a$ and so 0 is an identity for $(\mathbb{N}_0, \ast)$. Since $a \ast a = |a - a| = 0$ for all $a \in \mathbb{N}_0$, it follows that $a$ is an inverse of itself. Because $|a - b| = |b - a|$, we have $a \ast b = b \ast a$ and $(\mathbb{N}_0, \ast)$ is commutative. Hence, $(\mathbb{N}_0, \ast)$ satisfies properties G2–G4.

**Example 15.4**
Let $\ast$ be the binary operation defined on $\mathbb{Z}$ by $a \ast b = a + b - 1$ for $a, b \in \mathbb{Z}$, where the operations indicated in $a + b - 1$ are ordinary addition and subtraction. Determine which of the four properties G1–G4 are satisfied by $(\mathbb{Z}, \ast)$.

**Solution**
For integers $a, b$ and $c$,
\[
a \ast (b \ast c) = a \ast (b + c - 1) = a + (b + c - 1) - 1 = a + b + c - 2,
\]
while
\[
(a \ast b) \ast c = (a + b - 1) \ast c = (a + b - 1) + c - 1 = a + b + c - 2.
\]
Thus, $a \ast (b \ast c) = (a \ast b) \ast c$ and $(\mathbb{Z}, \ast)$ is associative. Since $a + b - 1 - b + a - 1$, it follows that $a \ast b = b \ast a$ for all $a, b \in \mathbb{Z}$ and so $(\mathbb{Z}, \ast)$ is commutative.

Let $a$ be an integer. Observe that $a \ast 1 = a + 1 - 1 = a$. Thus, 1 is an identity for $(\mathbb{Z}, \ast)$. For $b = -a + 2 \in \mathbb{Z}$, we have
\[
a \ast b = a \ast (-a + 2) = a + (-a + 2) - 1 = 1.
\]
Hence, $b$ is an inverse of $a$ and every integer has an inverse. Therefore, $(\mathbb{Z}, \ast)$ satisfies all four properties G1–G4.

**Analysis**
Let's discuss this example a bit more. It was shown that 1 is an identity for $(\mathbb{Z}, \ast)$. How did we know to choose 1? Actually, this was a natural choice since we were looking for an integer $e$ such that $a \ast e = a$ for every integer $a$. Since $a \ast e = a + e - 1 = a$, it follows that $e = 1$. The choice of $b = -a + 2$ for an inverse of $a$ comes from solving $a \ast b = a + b - 1 = 1$ for $b$.

**SECTION 15.1 EXERCISES**

15.1. Consider the algebraic structure $(S, \ast)$, where $S = \{x, y, z\}$ and $\ast$ is described in the table in Figure 15.2.
Compute
(a) $x \ast (y \ast z)$ and $(x \ast y) \ast z$.
(b) $x \ast (x \ast x)$ and $(x \ast x) \ast x$.
(c) $y \ast (y \ast y)$ and $(y \ast y) \ast y$.
(d) What conclusion can you draw from (a)–(c)?

15.2. For every pair $a, b$ of elements in the indicated sets, the element $a \ast b$ is defined. Which of these are binary operations? For those that are binary operations, determine which of the properties G1–G4 are satisfied.
(a) $a \ast b = 1$ on the set $\mathbb{Z}$
(b) $a \ast b = a/b$ on the set $\mathbb{N}$
(c) $a \ast b = a^b$ on the set $\mathbb{N}$
(d) $a \ast b = \max \{a, b\}$ on the set $\mathbb{N}$
15.2 Groups

One of the most elementary, yet fundamental, characteristics of the algebraic structure \((\mathbb{Z}, +)\) is the ability to solve linear equations, that is, equations of the type \(a + x = b\). By this, we mean that given integers \(a\) and \(b\), we seek an integer \(x\) for which \(a + x = b\). How does one solve this equation? First, we are well aware that \((\mathbb{Z}, +)\) has an identity element \(0\). Also, \(a\) has \(-a\) as an inverse. If we add \(-a\) to \(a + x\), which is the same as adding \(-a\) to \(b\) since \(a + x\) and \(b\) are the same integer, then we obtain

\[-a + (a + x) = -a + b.\]  \hspace{1cm} (15.1)
Chapter 15  Proofs in Group Theory

Applying the associative law to (15.1), we now obtain

\[-a + x = -a + b\]

and so

\[0 + x = -a + b.\]

This tells us that if \(a + x = b\) has a solution, then the only possible solution is \(-a + b\).

It doesn’t tell us that \(-a + b\) is actually a solution, but we can easily take care of this.

Letting \(x = -a + b\), we have

\[a + x = a + (-a + b) = (a + (-a)) + b = 0 + b = b.\]

Of course, since \((\mathbb{Z}, +)\) also satisfies the commutative property, the solution \(-a + b\) can also be written as \(b + (-a) = b - a\).

Let’s look at the related linear equation when the operation is multiplication, say in \((\mathbb{R}^*, \cdot)\). Here, for \(a, b \in \mathbb{R}^*\), we seek \(x \in \mathbb{R}^*\) such that \(a \cdot x = b\). Recall that 1 is an identity element in \((\mathbb{R}^*, \cdot)\). Multiplying both sides of \(a \cdot x = b\) by \(\frac{1}{a}\) (which belongs to \(\mathbb{R}^*\)), we obtain

\[\frac{1}{a} \cdot (a \cdot x) = \frac{1}{a} \cdot b = \frac{b}{a}.\]  (15.2)

Applying the associative law to (15.2), we obtain

\[\frac{1}{a} \cdot (a \cdot x) = \left(\frac{1}{a} \cdot a\right) \cdot x = 1 \cdot x = x.\]

Therefore, \(x = b/a\). To show that \(\frac{b}{a}\) is, in fact, a solution of \(a \cdot x = b\), we let \(x = \frac{b}{a}\) and obtain

\[a \cdot x = a \left(\frac{b}{a}\right) = b.\]

The solutions of the two equations that we have just discussed should look very familiar to you. However, these have been given to illustrate a more general situation. Suppose that we have an algebraic structure \((S, \ast)\) in which we would like to solve all linear equations, that is, for \(a, b \in S\), we wish to show that there exists an element \(x \in S\) such that \(a \ast x = b\). If \((S, \ast)\) is associative, has an identity \(e\) and \(a\) has an inverse \(s \in S\), then we have \(s \ast (a \ast x) = s \ast b\) and so

\[s \ast (a \ast x) = (s \ast a) \ast x = e \ast x = x = s \ast b.\]

To show that \(s \ast b\) is, in fact, a solution of the linear equation \(a \ast x = b\), we let \(x = s \ast b\) and obtain

\[a \ast x = a \ast (s \ast b) = (a \ast s) \ast b = e \ast b = b,\]

and so \(s \ast b\) is a solution.

You might now have observed that in order to solve all linear equations in an algebraic structure \((S, \ast)\), it is necessary that \((S, \ast)\) satisfy the three properties G1 – G3 (property G4 is not required). Algebraic structures that satisfy properties G1 – G3 are so important in abstract algebra that they are given a special name and will be the major emphasis of this chapter.
A **group** is a nonempty set $G$ together with a binary operation $*$ that satisfies the following three properties:

**G1** **Associative Law:** $a * (b * c) = (a * b) * c$ for all $a, b, c \in G$;

**G2** **Existence of Identity:** There exists an element $e \in G$ such that $a * e = e * a = a$ for every $a \in G$;

**G3** **Existence of Inverses:** For each element $a \in G$, there exists an element $s \in G$ such that $a * s = s * a = e$.

Hence, a group is a special kind of algebraic structure $(G, *)$, namely, one that satisfies properties G1 – G3. If the operation $*$ is clear, then we often denote this group simply by $G$ rather than by $(G, *)$. An element $e \in G$ satisfying property G2 is called an **identity** for the group $G$, while an element $s$ satisfying property G3 is called an **inverse** of $a$.

If a group $G$ also satisfies the commutative property G4, then $G$ is called an **abelian group**, a term named after the Norwegian mathematician Niels Henrik Abel. If a group $G$ does not satisfy G4, then $G$ is called a **nonabelian group**. We have now seen several abelian groups, namely, $(\mathbb{Z}, +)$, $(\mathbb{Q}, +)$, $(\mathbb{R}, +)$, $(\mathbb{Z}_n, +)$, $(\mathbb{Q}^+, \cdot)$, $(\mathbb{R}^+, \cdot)$ and $(\mathbb{R}^*, \cdot)$, as well as the algebraic structure $(\mathbb{Z}, *)$ described in Example 15.4.

The **order of a group** $G$, denoted by $|G|$, is the cardinality of $G$. If the order of $G$ is finite, then $G$ is a **finite group**; while if $G$ has an infinite number of elements, then $G$ is an **infinite group**. All of the groups given above are infinite groups except for $(\mathbb{Z}_n, +)$ which has order $n$. If a finite group $G$ has relatively few elements, then we often describe the operation $*$ by means of a table, called a **group table** (or **operation table**). For example, the group tables for $(\mathbb{Z}_3, +)$ and $(\mathbb{Z}_4, +)$ are shown in Figure 15.3.

![Figure 15.3 The group tables for $(\mathbb{Z}_3, +)$ and $(\mathbb{Z}_4, +)$](image-url)

Although $(\mathbb{Z}_n, +)$ is a group for every integer $n \geq 2$, $(\mathbb{Z}_n, \cdot)$ is not a group for any $n \geq 2$, since, as we have mentioned, the element $[0]$ has no inverse. This suggests considering the set $\mathbb{Z}_n^* = \mathbb{Z}_n - \{[0]\} = \{[1], [2], \ldots, [n-1]\}$, $n \geq 2$, under multiplication. For some integers $n \geq 2$, multiplication is not a binary operation on $\mathbb{Z}_n^*$. For example, $[2] \in \mathbb{Z}_4^*$ but $[2] \cdot [2] = [0] \notin \mathbb{Z}_4^*$. On the other hand, multiplication is a binary operation on $\mathbb{Z}_5^*$. In fact, $(\mathbb{Z}_5^*, \cdot)$ satisfies properties G1, G2 and G4, where $[1]$ is an identity. Since $[1] \cdot [1] = [1], [2] \cdot [3] = [3] \cdot [2] = [1]$ and $[4] \cdot [4] = [1], \ [1] \cdot [1] = [1], [2] \cdot [3] = [3] \cdot [2] = [1]$ and $[4] \cdot [4] = [1]$, every element of $(\mathbb{Z}_5^*, \cdot)$ has an inverse. Therefore, $(\mathbb{Z}_5^*, \cdot)$ satisfies property G3 as well and so is an abelian group. This, of course, brings up the question of which algebraic structures $(\mathbb{Z}_n^*, \cdot)$ are groups. Perhaps the examples above suggest the answer.
The set $\mathbb{Z}_n^*$, $n \geq 2$, is a group under multiplication if and only if $n$ is a prime.

**Theorem to Prove**

If $n$ is a composite number, then there exist integers $a$ and $b$ such that $2 \leq a, b \leq n - 1$ and $n = ab$. So, $[a], [b] \in \mathbb{Z}_n^*$ and $[a][b] = [n] = [0] \notin \mathbb{Z}_n^*$ and multiplication is not a binary operation. Therefore, the only possibility for $(\mathbb{Z}_n^*, \cdot)$ to be a group is when $n$ is a prime.

Suppose then that $p$ is a prime. First, we need to verify that multiplication is in fact a binary operation on $\mathbb{Z}_p^*$, that is, if $[a], [b] \in \mathbb{Z}_p^*$, then $[a][b] \in \mathbb{Z}_p^*$. If $[ab] \notin \mathbb{Z}_p^*$, then $[ab] = [0]$: so $ab \equiv 0 \pmod{p}$, which implies that $p | ab$. By Corollary 12.14, $p | a$ or $p | b$ and so $[a] = [0]$ or $[b] = [0]$. That is, either $[a] \notin \mathbb{Z}_p^*$ or $[b] \notin \mathbb{Z}_p^*$, a contradiction.

To show that $(\mathbb{Z}_p^*, \cdot)$ is a group, it remains only to verify that property G3 is satisfied. Let $r$ be an integer with $1 \leq r \leq p - 1$. We need to show that $[r]$ has an inverse, that is, there exists $[s] \in \mathbb{Z}_p^*$ such that $[r][s] = [1]$. Since $p$ is a prime and $1 \leq r \leq p - 1$, the integers $r$ and $p$ are relatively prime. By Theorem 12.12, the integer 1 is a linear combination of $r$ and $p$. So, there exist integers $x$ and $y$ such that $1 = rx + py$. Using the definition of addition and multiplication in $\mathbb{Z}_p$, and observing that $[p] = [0]$ in $\mathbb{Z}_p$, we have

$$[1] = [rx + py] = [rx] + [py] = [r] \cdot [x] + [p] \cdot [y]$$

$$= [r] \cdot [x] + [0] \cdot [y] = [r] \cdot [x] + [0] = [r] \cdot [x].$$

Hence, $[x]$ is an inverse for $[r]$.

We now give a concise proof of the theorem.

**Theorem 15.5** The set $\mathbb{Z}_n^*$, $n \geq 2$, is a group under multiplication if and only if $n$ is a prime.

**Proof** Assume that $n$ is a composite number. Then there exist integers $a$ and $b$ such that $2 \leq a, b \leq n - 1$ and $n = ab$. Hence, $[a], [b] \in \mathbb{Z}_n^*$ and $[a][b] = [n] = [0] \notin \mathbb{Z}_n^*$, which implies that multiplication is not a binary operation on $\mathbb{Z}_n^*$, and so $\mathbb{Z}_n^*$ is not a group under multiplication.

For the converse, assume that $p$ is a prime. First, we show that multiplication is a binary operation on $\mathbb{Z}_p^*$. Assume, to the contrary, that it is not. Then there exist $[a], [b] \in \mathbb{Z}_p^*$ such that $[a][b] \notin \mathbb{Z}_p^*$. Since $[a][b] \notin \mathbb{Z}_p^*$, it follows that $[a][b] = [ab] = [0]$. Thus, $ab \equiv 0 \pmod{p}$ and so $p | ab$. By Corollary 12.14, $p | a$ or $p | b$. Therefore, $[a] = [0]$ or $[b] = [0]$, which contradicts the fact that $[a], [b] \in \mathbb{Z}_p^*$.

Hence, $(\mathbb{Z}_p^*, \cdot)$ is an algebraic structure that satisfies properties G1 and G2. It remains to show that $(\mathbb{Z}_p^*, \cdot)$ satisfies property G3. Let $[r] \in \mathbb{Z}_p^*$, where we can assume that $1 \leq r \leq p - 1$. Since $r$ and $p$ are relatively prime, 1 is a linear combination of $r$ and $p$ by Theorem 12.12. Thus, $1 = rx + py$ for some integers $x$ and $y$. So,

$$[1] = [rx + py] = [rx] + [py] = [r] \cdot [x] + [p] \cdot [y]$$

$$= [r] \cdot [x] + [0] \cdot [y] = [r] \cdot [x].$$

Thus, $[x]$ is an inverse for $[r]$ and $(\mathbb{Z}_p^*, \cdot)$ is a group.
By Theorem 15.5, for every prime $p$, $(\mathbb{Z}_p^*, \cdot)$ is an abelian group of order $p - 1$. Another example of an abelian group is $(G, \ast)$, where $G = \{a, b, c\}$ and $\ast$ is defined in Figure 15.4. It is not difficult to see that $a$ is an identity for $(G, \ast)$ and that $a, b$ and $c$ are inverses for $a, c$ and $b$, respectively. Since $a \ast b = b \ast a, a \ast c = c \ast a$ and $b \ast c = c \ast b$, it follows that $G$ is abelian. We have one additional property to verify to show that $G$ is a group, however, namely, the associative property. What we are required to show is that $x \ast (y \ast z) = (x \ast y) \ast z$ for all $x, y, z \in G$. Since there are three choices for each of $x, y$ and $z$, we have 27 equalities to verify. Because $b \ast (c \ast b) = b \ast a = b$ and $(b \ast c) \ast b = a \ast b = b$, it follows that $b \ast (c \ast b) = (b \ast c) \ast b$. Since the remaining 26 equalities can also be verified, $G$ is, in fact, an abelian group.

![Figure 15.4 An abelian group with three elements](image-url)

We mentioned earlier that the algebraic structure $(M_2(\mathbb{R}), \cdot)$ does not satisfy property G3 even though it does satisfy property G2. The matrix $I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ is an identity for $(M_2(\mathbb{R}), \cdot)$. Furthermore, a matrix $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \in M_2(\mathbb{R})$ has an inverse if and only if its determinant $\det A = ad - bc \neq 0$. In this case,

$$B = \frac{1}{ad - bc} \begin{bmatrix} d & -b \\ -c & a \end{bmatrix}$$

is an inverse for $A$ and so $AB = BA = I$. Let

$$M_2^+(\mathbb{R}) = \{A \in M_2(\mathbb{R}) : \det A \neq 0\}.$$ 

Since $\det(AB) = \det(A) \cdot \det(B)$ for all $A, B \in M_2(\mathbb{R})$, it follows that if $A, B \in M_2^+(\mathbb{R})$, then $AB \in M_2^+(\mathbb{R})$ and so $M_2^+(\mathbb{R})$ is closed under matrix multiplication. This implies that $(M_2^+(\mathbb{R}), \cdot)$ is a group. On the other hand, since the matrices

$$A = \begin{bmatrix} 1 & 1 \\ 1 & 0 \end{bmatrix} \text{ and } B = \begin{bmatrix} 0 & 1 \\ 1 & 1 \end{bmatrix}$$

belong to $M_2^+(\mathbb{R})$ and

$$AB = \begin{bmatrix} 1 & 2 \\ 0 & 1 \end{bmatrix} \text{ and } BA = \begin{bmatrix} 1 & 0 \\ 2 & 1 \end{bmatrix},$$

it follows that $(M_2^+(\mathbb{R}), \cdot)$ is a nonabelian group.
410   Chapter 15  Proofs in Group Theory

SECTION 15.2 EXERCISES

15.8. Let \( S = \{a, b, c, d\} \). Figure 15.5 shows a partially completed table for an associative binary operation \(*\) defined on \( S \).
   (a) Complete the table.
   (b) Is the algebraic structure \((S, *)\) a group?

\[
\begin{array}{cccc}
\ast & a & b & c & d \\
\hline
a & a & c &  &  \\
b &  &  & a &  \\
c & d & a &  &  \\
d &  &  & b &  \\
\end{array}
\]

**Figure 15.5** A binary operation on the set \( S = \{a, b, c, d\} \) in Exercise 15.8

15.9. Let \((G, \ast)\) be a group with \( G = \{a, b, c, d\} \), where a partially completed table for \((G, \ast)\) is given in Figure 15.6. Complete the table.

\[
\begin{array}{cccc}
\ast & a & b & c & d \\
\hline
a & d & c &  &  \\
b &  &  & a &  \\
c &  &  &  &  \\
d &  &  &  &  \\
\end{array}
\]

**Figure 15.6** A partially completed table for \((G, \ast)\) in Exercise 15.9

15.10. None of the following binary operations \(*\) on the given set results in a group. Which is the first property among G1, G2, G3 that fails?
   (a) Let \(*\) be defined on \( \mathbb{R}^+ \) by \( a \ast b = \sqrt{ab} \).
   (b) Let \(*\) be defined on \( \mathbb{R}^* \) by \( a \ast b = a/b \).
   (c) Let \(*\) be defined on \( \mathbb{R}^+ \) by \( a \ast b = a + b + ab \).

15.11. (a) Determine whether for all \([a], [b] \in \mathbb{Z}_6^* = \{[1], [2], [3], [4], [5]\}, \) there exists \([x] \in \mathbb{Z}_6^* \) such that \([a][x] = [b] \).
   (b) Why is the answer to the question posed in (a) not surprising?

15.12. Let \( G = \left\{ \begin{bmatrix} a & b \\ 0 & 0 \end{bmatrix} : a, b \in \mathbb{R} \text{ and } a \neq 0 \right\} \).
   (a) Prove that \( G \) is closed under matrix multiplication.
   (b) Prove that there exists \( E \in G \) such that \( E \cdot A = A \) for all \( A \in G \).
   (c) Prove for each \( A \in G \) that there is \( A' \in G \) such that \( A \cdot A' = E \).
   (d) Prove or disprove: \((G, \cdot)\) is a group.
15.3 Permutation Groups

One of the most important classes of groups concerns a concept introduced in Chapter 10 and visited again in Chapter 13. Recall that a permutation of a nonempty set \(A\) is a bijective function \(f : A \to A\), that is, \(f\) is one-to-one and onto. In Chapter 10, it was shown that:

1. the composition of every two permutations of \(A\) is a permutation of \(A\);
2. composition of permutations of \(A\) is an associative operation;
3. the identity function \(i_A : A \to A\) defined by \(i_A(a) = a\) for all \(a \in A\) is a permutation of \(A\);
4. every permutation of \(A\) has an inverse, which is also a permutation of \(A\).

By a permutation group we mean a group \((G, \circ)\), where \(G\) is a set of permutations of some set \(A\) and \(\circ\) denotes composition. Let \(S_A\) denote the set of all permutations of \(A\). Then by (1) – (4) above, we have the following result.

**Theorem 15.6** For every nonempty set \(A\), the algebraic structure \((S_A, \circ)\) is a permutation group.

The group \((S_A, \circ)\) is called the symmetric group on \(A\). Therefore, every symmetric group is a permutation group.

We have already noted that for the set \(F_R\) of all functions from \(R\) to \(R\), \((F_R, \circ)\) is an algebraic structure, where \(\circ\) denotes function composition. By Theorem 15.6, for the set \(S_R\) of bijective functions from \(R\) to \(R\), the algebraic structure \((S_R, \circ)\) is a group, namely, the symmetric group on \(R\). The identity function \(i_R\) in \(S_R\), defined by \(i_R(x) = x\) for all \(x \in R\), is an identity in the group \((S_R, \circ)\).

The functions \(f\) and \(g\) defined by

\[
f(x) = x + 1 \text{ and } g(x) = 2x
\]

for all \(x \in R\) belong to \(S_R\); however, since

\[
(f \circ g)(x) = f(g(x)) = f(2x) = 2x + 1 \text{ and } (g \circ f)(x) = g(f(x)) = g(x + 1) = 2x + 2,
\]

it follows that \(f \circ g \neq g \circ f\) and so \((S_R, \circ)\) is a nonabelian group.

If \(A = \{1, 2, \cdots, n\}\), where \(n \in N\), the group \(S_A\) is commonly denoted by \(S_n\). The group \((S_n, \circ)\) has \(n!\) elements and is commonly called the symmetric group (of degree \(n\)). The symmetric group \((S_n, \circ)\) is therefore a finite group of order \(n!\). By the notation introduced in Chapter 10, \(S_3 = \{\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5, \alpha_6\}\), where
Recall that with this notation for a permutation, an element of \{1, 2, 3\} listed in the first row maps into the element in the second row directly below it. Thus, \(\alpha_1\) is the identity of \(S_3\). Let’s consider the composition \(\alpha_3 \circ \alpha_6\). For example,

\[
(\alpha_3 \circ \alpha_6)(1) = \alpha_3(\alpha_6(1)) = \alpha_3(3) = 1.
\]

Also, \((\alpha_3 \circ \alpha_6)(2) = 3\) and \((\alpha_3 \circ \alpha_6)(3) = 2\). Therefore,

\[
\alpha_3 \circ \alpha_6 = \left( \begin{array}{ccc} 1 & 2 & 3 \\ 3 & 2 & 1 \end{array} \right) \circ \left( \begin{array}{ccc} 1 & 2 & 3 \\ 3 & 1 & 2 \end{array} \right) = \left( \begin{array}{ccc} 1 & 2 & 3 \\ 1 & 3 & 2 \end{array} \right) = \alpha_2.
\]

Similarly \(\alpha_6 \circ \alpha_3 = \alpha_4\). Hence, \(\alpha_3 \circ \alpha_6 \neq \alpha_6 \circ \alpha_3\). Therefore, \((S_3, \circ)\) is a nonabelian group. This shows that there is a nonabelian group of order 6. There is no nonabelian group having order less than 6, however.

When taking the composition of two elements \(\alpha, \beta \in S_n\), where \(n \in \mathbb{N}\), we often write \(\alpha \circ \beta\) as \(\alpha \beta\) and say that we are “multiplying” \(\alpha\) and \(\beta\). With this notation, we have \(\alpha_3 \alpha_6 = \alpha_2, \alpha_6 \alpha_3 = \alpha_4, \alpha_3^2 = \alpha_3 \alpha_3 = \alpha_1\) and \(\alpha_6^2 = \alpha_6 \alpha_6 = \alpha_5\). The group table for \((S_3, \circ)\) is shown in Figure 15.7 (containing all 36 products!).

![Figure 15.7 The group table for \((S_3, \circ)\) (contains all 36 products)](image)

A permutation group need not consist of all permutations of some set \(A\). For example, if we consider the subsets \(G_1 = \{\alpha_1, \alpha_2\}\) and \(G_2 = \{\alpha_3, \alpha_6\}\) of \(S_3\), then \((G_1, \circ)\) and \((G_2, \circ)\) are both permutation groups. Their group tables are shown in Figure 15.8.

Also, let

\[
\beta_1 = \left( \begin{array}{cccc} 1 & 2 & 3 & 4 \\ 1 & 2 & 3 & 4 \end{array} \right) \quad \beta_2 = \left( \begin{array}{cccc} 1 & 2 & 3 & 4 \\ 2 & 1 & 3 & 4 \end{array} \right)
\]

be permutations of the set \{1, 2, 3, 4\} and let \(G_3 = \{\beta_1, \beta_2, \beta_3, \beta_4\}\). Then \((G_3, \circ)\) is an abelian permutation group, whose group table is shown in Figure 15.9.
During the latter part of the 18th century, a major problem in mathematics concerned whether the roots of every fifth degree polynomial with real coefficients could be expressed in terms of radicals and the usual operations of arithmetic. It was well known that the roots of a quadratic polynomial $ax^2 + bx + c$, where $a, b, c \in \mathbb{R}$ and $a \neq 0$, are $\frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$ and $\frac{-b - \sqrt{b^2 - 4ac}}{2a}$, which is a consequence of the quadratic formula. Furthermore, it had been known since the 16th century, that the roots of all third degree (cubic) and fourth degree (quartic) polynomials with real coefficients could be described in terms of radicals and the standard operations of arithmetic. But fifth degree polynomials proved to be another story. However, in 1824 Niels Henrik Abel proved that the roots of fifth degree polynomials with real coefficients could not, in general, be expressed in such a way. From this, it follows that for every integer $n \geq 5$, there exist polynomials of degree $n$ with real coefficients whose roots cannot be expressed in terms of radicals and the standard operations of arithmetic. His work went unnoticed, however, until after his death at age 26.

Some time later the French mathematician Évariste Galois characterized those polynomials of degree 5 and greater whose roots can be expressed in terms of radicals and ordinary arithmetic. Like Abel, Galois died very early (at age 20), but in his case from an unlikely cause: a duel. Galois’ work also was not recognized until eleven years after his death when Joseph Liouville addressed the Academy of Sciences in Paris: “I hope to interest the Academy in announcing that among the papers of Évariste Galois I have found a solution, as precise as it is profound, of this beautiful problem: whether or not it is solvable by radicals.”
In developing his theory, Galois associated, with a given polynomial, a set $G$ of permutations of the roots of the polynomial. This set $G$ had the property that whenever $s, t \in G$, then the composition $s \circ t \in G$, that is, $G$ was closed under composition. He referred to $G$ as a "group," a term that enjoys a permanent and prominent place in abstract algebra.

**SECTION 15.3 EXERCISES**

15.14. For $1 \leq i \leq 6$, each function $f_i$ is a permutation on the set $\mathbb{Q} - \{0, 1\}$:

- $f_1(x) = x$
- $f_2(x) = 1 - x$
- $f_3(x) = \frac{1}{x}$
- $f_4(x) = \frac{2 - x}{x - 1}$
- $f_5(x) = \frac{1}{1 - x}$
- $f_6(x) = \frac{x}{x - 1}$

Show that the set $F = \{f_1, f_2, \ldots, f_6\}$ is a group under composition.

15.15. Prove that if $A$ is a set with at least three elements, then the symmetric group $(S_A, \circ)$ is nonabelian.

15.16. Give examples of the following (if they exist):

(a) a finite abelian group
(b) a finite nonabelian group
(c) an infinite abelian group
(d) an infinite nonabelian group.

15.17. Determine all elements $x$ in the group $S_3$ such that $x^2 = \alpha_1$ and all those elements $y$ in $S_3$ such that $y^3 = \alpha_1$.

15.18. For the permutations:

- $\gamma_1 = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 1 & 2 & 3 & 4 \end{pmatrix}$
- $\gamma_2 = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 2 & 3 & 4 & 1 \end{pmatrix}$
- $\gamma_3 = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 3 & 4 & 1 & 2 \end{pmatrix}$
- $\gamma_4 = \begin{pmatrix} 1 & 2 & 3 & 4 \\ 4 & 1 & 2 & 3 \end{pmatrix}$

of the set $\{1, 2, 3, 4\}$, show that the set $G = \{\gamma_1, \gamma_2, \gamma_3, \gamma_4\}$ under composition is an abelian group.

15.19. Consider the following permutations on the set $A = \{1, 2, 3, 4, 5\}$.

- $\beta_1 = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 1 & 2 & 3 & 4 & 5 \end{pmatrix}$
- $\beta_2 = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 3 & 1 & 4 & 5 \end{pmatrix}$
- $\beta_3 = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 1 & 2 & 4 & 5 \end{pmatrix}$
- $\beta_4 = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 1 & 2 & 3 & 4 & 5 \end{pmatrix}$
- $\beta_5 = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 2 & 3 & 1 & 5 & 4 \end{pmatrix}$
- $\beta_6 = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 \\ 3 & 1 & 2 & 5 & 4 \end{pmatrix}$

For $G = \{\beta_1, \beta_2, \ldots, \beta_6\}$, show that $(G, \circ)$ is a group of permutations on $A$.

15.20. For a permutation group $G$ on a set $A$, a relation $R$ is defined on $A$ by $a R b$ if there exists $g \in G$ such that $g(a) = b$.

(a) Prove that $R$ is an equivalence relation on $A$. (The equivalence classes resulting from this equivalence relation $R$ are called the orbits of $A$ under $G$.)
(b) For the group $G$ in Exercise 15.19, determine the orbits of $A$ under $G$.

**15.4 FUNDAMENTAL PROPERTIES OF GROUPS**

We now consider some properties possessed by all groups. Of course, any property satisfied by all groups must be a consequence of properties G1 – G3. Unless stated otherwise, the symbol $e$ represents an identity in the group under consideration. One simple, but
important, property satisfied by every group \((G, \ast)\) allows us to cancel \(a\) in \(a \ast b = a \ast c\) and conclude that \(b = c\). Actually, since a group need not be abelian, there are two such cancellation properties.

**Theorem 15.7**

Every group \((G, \ast)\) satisfies:

(a) **The Left Cancellation Law** Let \(a, b, c \in G\). If \(a \ast b = a \ast c\), then \(b = c\).

(b) **The Right Cancellation Law** Let \(a, b, c \in G\). If \(b \ast a = c \ast a\), then \(b = c\).

**Proof** We prove (a) only since the proof of (b) is similar. (See Exercise 15.21.) Assume that \(a \ast b = a \ast c\) and let \(s\) be an inverse for \(a\). Then \(s \ast (a \ast b) = s \ast (a \ast c)\). So,

\[
s \ast (a \ast b) = (s \ast a) \ast b = e \ast b = b,
\]

while

\[
s \ast (a \ast c) = (s \ast a) \ast c = e \ast c = c.
\]

Therefore, \(b = c\).

The last two sentences of this proof could have been replaced by: So,

\[
b = e \ast b = (s \ast a) \ast b = s \ast (a \ast b) = s \ast (a \ast c) = (s \ast a) \ast c = e \ast c = c.
\]

The next result will come as no surprise.

**Theorem 15.8** Let \((G, \ast)\) be a group and let \(a, b \in G\). The linear equations \(a \ast x = b\) and \(x \ast a = b\) have unique solutions in \(G\).

**Proof** We prove only that \(a \ast x = b\) has a unique solution. (The remaining proof is left as Exercise 15.22.) Let \(e\) be an identity for \(G\), let \(s\) be an inverse of \(a\) and let \(x = s \ast b\). Then

\[
a \ast x = a \ast (s \ast b) = (a \ast s) \ast b = e \ast b = b.
\]

So \(x = s \ast b\) is a solution of the equation \(a \ast x = b\).

It remains to show that \(s \ast b\) is the only solution of \(a \ast x = b\). Suppose that \(x_1\) and \(x_2\) are solutions of \(a \ast x = b\). Then \(a \ast x_1 = b\) and \(a \ast x_2 = b\). Thus, \(a \ast x_1 = a \ast x_2\). Applying the Left Cancellation Law (Theorem 15.7(a)), we have \(x_1 = x_2\).

The preceding theorem provides some interesting information for us. Suppose that we have a group table for a group \(G\) and we are looking at the row corresponding to the element \(a\). Then this row contains the elements \(a \ast g\) for all \(g \in G\). Let \(b \in G\). By Theorem 15.8, there exists \(x \in G\) such that \(a \ast x = b\). That is, the element \(b\) must appear in the row corresponding to \(a\). This is illustrated in Figure 15.10. On the other hand, the element \(b\) cannot appear twice in this row since the equation \(a \ast x = b\) has a unique solution. Hence, we can conclude that every element of \(G\) appears exactly once in every row in the group table of \(G\). By considering the equation \(x \ast a = b\), we can likewise conclude that every element of \(G\) appears exactly once in every column in the group table of \(G\).
As with composition in a symmetric group, it is customary in a group $G$ to refer to the binary operation $*$ as “multiplication” and to indicate the “product” of elements $a$ and $b$ in $G$ by $ab$ rather than $a*b$ to simplify the notation. We thus write $a*a = aa = a^2$. The lone exception to this practice is when we have a group whose operation is addition, in which case we continue to use $+$ as the operation. It is also common practice never to use $+$ as an operation when the group is nonabelian. Let’s use this newly adopted notation to present a theorem that shows that every group $G$ has a unique identity and every element of $G$ has a unique inverse, two facts that you may have already suspected were true.

**Theorem 15.9** Let $G$ be a group. Then

(a) $G$ has a unique identity and

(b) each element in $G$ has a unique inverse.

**Proof**

Assume that $e$ and $f$ are two identities in $G$. Since $e$ is an identity, $ef = f$; and since $f$ is an identity, $ef = e$. Thus, $e = ef = f$. This verifies (a).

Next let $g \in G$ and suppose that $s$ and $t$ are both inverses of $g$. So, $gs = sg = e$ and $gt = tg = e$. Since $gs = gt$, it follows by the Left Cancellation Law (Theorem 15.7(a)) that $s = t$. This verifies (b).

It is customary to denote the (unique) inverse of an element $a$ in a group by $a^{-1}$. If the operation in a group under consideration is addition, then we follow the standard practice of denoting the identity by 0 and the inverse of $a$ by $-a$. We now present two theorems involving inverses in a group.

**Theorem 15.10** Let $G$ be a group. If $a \in G$, then

$$(a^{-1})^{-1} = a.$$ 

**Proof**

Since $aa^{-1} = a^{-1}a = e$, the element $a$ is the inverse of $a^{-1}$, that is, $(a^{-1})^{-1} = a$. 

For elements $a$ and $b$ in a group, the next theorem establishes a connection among the inverses $a^{-1}$, $b^{-1}$ and $(ab)^{-1}$.

**Theorem to Prove**

Let $G$ be a group. For $a, b \in G$,

$$(ab)^{-1} = b^{-1}a^{-1}.$$
PROOF STRATEGY
The product of the elements $a$ and $b$ of $G$ is $ab$. Since $ab \in G$, the element $ab$ has an inverse – indeed a unique inverse. The inverse of $ab$ is denoted by $(ab)^{-1}$. The theorem claims that the inverse of $ab$ is the element $b^{-1}a^{-1}$ in $G$. To show that an element $s \in G$ is an inverse of $x \in G$, we are required to show that $sx = xs = e$. Therefore, to show that $b^{-1}a^{-1}$ is the inverse of $ab$, we need to show that $(ab)(b^{-1}a^{-1}) = (b^{-1}a^{-1})(ab) = e$. 

Theorem 15.11 Let $G$ be a group. If $a, b \in G$, then

$$(ab)^{-1} = b^{-1}a^{-1}. \quad \spadesuit$$

Proof
To show that $b^{-1}a^{-1}$ is the inverse of $ab$, it suffices to show that $(ab)(b^{-1}a^{-1}) = e$ and $(b^{-1}a^{-1})(ab) = e$. We verify the first of these as the proof of the second equality is similar. Observe that

$$(ab)(b^{-1}a^{-1}) = ((ab)b^{-1})a^{-1} = (a(bb^{-1}))a^{-1} = (ae)a^{-1} = aa^{-1} = e. \quad \blacksquare$$

In words, what Theorem 15.11 states is that the inverse of the product of two elements in a group is the product of the inverses of these two elements in reverse order. Of course, if $G$ is an abelian group and $a, b \in G$, then the order of the product of $a^{-1}$ and $b^{-1}$ doesn’t matter, that is, $(ab)^{-1} = b^{-1}a^{-1} = a^{-1}b^{-1}$. (See Exercise 15.25.)

In general then, if $g$ is an element of a group $G$, then $g^2 = gg$, while for $n \geq 3$, $g^n$ is defined as $gg \cdots g$ ($n$ elements $g$). As mentioned above, $g^{-1}$ denotes the unique inverse of $g$. The inverse of $g^2$ is $(g^{-1})^2$, which we write as $g^{-2}$. Also, $g^{-2} = g^{-1}g^{-1} = (g^{-1})^2$. More generally, for $n \geq 3$,

$$g^{-n} = (g^{-1})^n = (g^n)^{-1}. \quad \spadesuit$$

In addition, $g^0$ is defined to be $e$, the identity of $G$. If $G$ is abelian and $g, h \in G$, then

$$(gh)^n = g^n h^n \text{ for each integer } n. \quad (15.3)$$

SECTION 15.4 EXERCISES

15.21. Prove Theorem 15.7(b) (The Right Cancellation Law): Let $(G, *)$ be a group. If $b * a = c * a$, where $a, b, c \in G$, then $b = c$.

15.22. Prove the following (see Theorem 15.8): Let $(G, *)$ be a group and let $a, b \in G$. The linear equation $x * a = b$ has a unique solution $x$ in $G$.

15.23. Let $(G, *)$ be a group and let $a, b, c \in G$. Prove that each of the following equations has a unique solution for $x$ in $G$ and determine the solution.

(a) $a * x * b = c$ \quad (b) $a * b * x = c$.

15.24. Let $a$ and $b$ be two elements in a group $G$. Prove that if $a$ and $b$ commute, then $a^{-1}$ and $b^{-1}$ commute.

15.25. Let $G$ be a group. Prove that $G$ is abelian if and only if $(ab)^{-1} = a^{-1}b^{-1}$ for all $a, b \in G$.

15.26. Construct a table for the group $(\mathbb{Z}_9, +)$ listing the elements of $\mathbb{Z}_9$ across the top of the table in some order and along the left side of the table in some order in such a way that every element of $\mathbb{Z}_9$ appears in each of the nine $3 \times 3$ regions indicated in the table in Figure 15.11.
Figure 15.11 Constructing a table for the group \((\mathbb{Z}_9, +)\) in Exercise 15.26.

15.27. By Theorem 15.9, every group \(G\) has a unique identity. That is, \(G\) contains only one element \(e\) such that \(ae = ea = a\) for all \(a \in G\). Suppose that \(e'\) is an element of \(G\) such that \(e'b = b\) for some element \(b \in G\). Prove or disprove: \(e'\) is the identity of \(G\).

15.28. Let \((G, \ast)\) be a group. Prove that if \(g \ast g = e\) for all \(g \in G\), then \(G\) is abelian.

15.29. Let \((G, \ast)\) be a finite group of even order. Prove that there exists \(g \in G\) such that \(g \neq e\) and \(g \ast g = e\).

15.30. Suppose that \(G\) is a finite abelian group of order \(n\), say \(G = \{g_1, g_2, \ldots, g_n\}\). Let \(g = g_1g_2 \cdots g_ng_1g_2 \cdots g_n\). What is \(g\)?

### 15.5 SUBGROUPS

There have been occasions when we were considering a group \((G, \ast)\) and a subset \(H\) of \(G\) such that \(H\) is a group under the same operation \(\ast\), that is, \((H, \ast)\) is also a group. If \((G, \ast)\) is a group and \(H\) is a subset of \(G\) such that \((H, \ast)\) is a group, then \((H, \ast)\) is called a subgroup of \(G\). For example, \((\mathbb{Z}, +)\) is a subgroup of \((\mathbb{Q}, +)\), which, in turn, is a subgroup of \((\mathbb{R}, +)\). Also, the groups \(G_1\) and \(G_2\) in Figure 15.8 are subgroups of \(S_3\), while the group \(G_3\) in Figure 15.9 is a subgroup of \(S_4\). If \((G, \ast)\) is a group with identity \(e\), then \((\{e\}, \ast)\) and \((G, \ast)\) are always subgroups of \((G, \ast)\). Hence, if \(G\) has at least two elements, then \(G\) has at least two subgroups.

The group \((2\mathbb{Z}, +)\) of even integers under addition is a subgroup of \((\mathbb{Z}, +)\). To see this, first observe that \(2\mathbb{Z} \subseteq \mathbb{Z}\). Since the sum of two even integers is an even integer, \(2\mathbb{Z}\) is closed under addition. Since the associative law of addition holds in \(\mathbb{Z}\), it holds in \(2\mathbb{Z}\) as well. The identity in \((\mathbb{Z}, +)\) is 0. Since 0 is an even integer, \(0 \in 2\mathbb{Z}\). Finally, the additive inverse (the negative) of an even integer is an even integer. Thus, \((2\mathbb{Z}, +)\) is a group. Therefore, showing that \((2\mathbb{Z}, +)\) is a subgroup of \((\mathbb{Z}, +)\) is simpler than showing that it is a group. This observation is true for every subgroup.

**Theorem 15.12** (The Subgroup Test) A nonempty subset \(H\) of a group \(G\) is a subgroup of \(G\) if and only if (1) \(ab \in H\) for all \(a, b \in H\) and (2) \(a^{-1} \in H\) for all \(a \in H\).

**Proof** We first show that if \(H\) is a subgroup of \(G\), then properties (1) and (2) are satisfied. Since \(H\) is closed under multiplication, property (1) is certainly satisfied. We now show that the identity \(e\) of \(G\) is also the identity of \(H\). Let \(f\) be the identity of \(H\). Thus, \(f \cdot f = f\).
Let $H = \left\{ \begin{bmatrix} a & b \\ c & 0 \end{bmatrix} : a, b, c \in \mathbb{R} \right\}$. Then $(H, +)$ is a group.

**Result 15.13** Let $H = \left\{ \begin{bmatrix} a & b \\ c & 0 \end{bmatrix} : a, b, c \in \mathbb{R} \right\}$. Then $(H, +)$ is a group.

**Proof** We show in fact that $(H, +)$ is a subgroup of $(M_2(\mathbb{R}), +)$. Certainly, $H$ is a nonempty subset of $M_2(\mathbb{R})$ since the zero matrix $\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ belongs to $H$. Let $A, B \in H$. Then

$$A = \begin{bmatrix} a_1 & a_2 \\ a_3 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} b_1 & b_2 \\ b_3 & 0 \end{bmatrix},$$

where $a_i, b_i \in \mathbb{R}$ ($1 \leq i \leq 3$). Then $A + B = \begin{bmatrix} a_1 + b_1 & a_2 + b_2 \\ a_3 + b_3 & 0 \end{bmatrix} \in H$ and the inverse of $A$ is $-A = \begin{bmatrix} -a_1 & -a_2 \\ -a_3 & 0 \end{bmatrix} \in H$. Consequently, by the Subgroup Test, $H$ is a subgroup of $M_2(\mathbb{R})$ and so $(H, +)$ is a group.
If $G$ is an abelian group, then we know that every two elements of $G$ commute. But even if $G$ is nonabelian, we know that its identity commutes with every element of $G$. However, there may very well be other elements of $G$ that commute with all elements of $G$. The set of all elements in a group $G$ that commute with every element in $G$ is called the center of $G$ and, in fact, is always a subgroup of $G$. This subgroup is often denoted by $Z(G)$. Since $Z(G) = G$ if and only if $G$ is abelian, the center is most interesting when $G$ is nonabelian.

**Result to Prove**  
For a group $G$, the center  

$$Z(G) = \{ a \in G : ga = ag \text{ for all } g \in G \}$$  

is a subgroup of $G$.

**Proof Strategy**  
To prove this result, it seems natural to use the Subgroup Test. Since $e \in Z(G)$, it follows that $Z(G) \neq \emptyset$. We are now required to show that $Z(G)$ satisfies the two properties required of the Subgroup Test.

First, we show that $Z(G)$ is closed under multiplication; that is, if $a, b \in Z(G)$, then $ab \in Z(G)$. We employ a direct proof. Let $a, b \in Z(G)$. To show that $ab \in Z(G)$, we need to show that $ab$ commutes with every element of $G$. So, let $g \in G$. We must show that $(ab)g = g(ab)$. This suggests starting with $(ab)g$. By the associative law, $(ab)g = a(bg)$. However, since $b \in Z(G)$, it follows that $a(bg) = a(gb)$. We can continue in this manner to complete the proof of this property.

Second, we need to show that if $a \in Z(G)$, then $a^{-1} \in Z(G)$. Again, we use a direct proof. Let $a \in Z(G)$. Then $a$ commutes with every element of $G$. To show that $a^{-1} \in Z(G)$, we need to verify that $a^{-1}$ commutes with every element of $G$. Let $g \in G$. We must show then that $a^{-1}g = ga^{-1}$ to complete the proof. But how do we do this? Theorem 15.11, which deals with inverses of elements, may be helpful. We know that $(xy)^{-1} = y^{-1}x^{-1}$ for all $x, y \in G$. So $(ag)^{-1} = g^{-1}a^{-1}$. This, however, involves $g^{-1}$. But if we start with $ag^{-1} = g^{-1}a$, then we have $(ag^{-1})^{-1} = (g^{-1}a)^{-1}$. ♦

**Result 15.14**  
For a group $G$, the center  

$$Z(G) = \{ a \in G : ga = ag \text{ for all } g \in G \}$$  

is a subgroup of $G$.

**Proof**  
Since $eg = ge$ for all $g \in G$, it follows that $e \in Z(G)$ and so $Z(G)$ is nonempty. First, we show that $Z(G)$ is closed under multiplication. Let $a, b \in Z(G)$. Thus, $ag = ga$ and $bg = gb$ for all $g \in G$. We show that $ab \in Z(G)$. Since  

$$(ab)g = a(bg) = a(gb) = (ga)b = (ga)b = g(ab),$$

$ab \in Z(G)$. Hence, $Z(G)$ is closed under multiplication. Next we show that every element of $Z(G)$ has an inverse in $Z(G)$. Let $a \in Z(G)$ and $g \in G$. We show that $a^{-1} \in Z(G)$, that is, $a^{-1}$ and $g$ commute. Since $a$ commutes with all elements of $G$, it follows that $a$ and $g^{-1}$ commute and so $ag^{-1} = g^{-1}a$. Since every element of $G$ has a unique inverse, $(ag^{-1})^{-1} = (g^{-1}a)^{-1}$. By Theorem 15.11, $(ag^{-1})^{-1} = (g^{-1})^{-1}a^{-1} = ga^{-1}$ and $(g^{-1}a)^{-1} = a^{-1}(g^{-1}a)^{-1} = a^{-1}g$. Therefore, $a^{-1}g = ga^{-1}$. ■
For \( A = \{1, 2, \cdots, n\} \), \( n \geq 2 \) and \( k \in A \), let \( G_k \) consist of those permutations \( \alpha \) in the symmetric group \( (S_n, \circ) \) such that \( \alpha(k) = k \) (that is, \( G_k \) consists of all those permutations of \( A \) that “stabilize” or fix \( k \)). The set \( G_k \) is called the stabilizer of \( k \) in \( S_n \).

**Result 15.15**

For integers \( k \) and \( n \) with \( 1 \leq k \leq n \) and \( n \geq 2 \), the stabilizer \( G_k \) of \( k \) in \( S_n \) is a subgroup of \( S_n \).

**Proof**

We use the Subgroup Test. Surely, the identity \( \alpha_0 \) in \( S_n \) belongs to \( G_k \), so \( G_k \neq \emptyset \). Let \( \alpha, \beta \in G_k \). Thus, \( \alpha(k) = \beta(k) = k \). Hence, \((\alpha \circ \beta)(k) = \alpha(\beta(k)) = \alpha(k) = k \) and so \( \alpha \circ \beta \in G_k \). Consider the inverse \( \alpha^{-1} \) of \( \alpha \). Thus, \( \alpha^{-1} \circ \alpha = \alpha_0 \). Therefore, \((\alpha^{-1} \circ \alpha)(k) = \alpha_0(k) = k \). Hence, \((\alpha^{-1} \circ \alpha)(k) = \alpha^{-1}(\alpha(k)) = \alpha^{-1}(k) = \alpha_0(k) = k \). Thus, \( \alpha^{-1} \in G_k \). By the Subgroup Test, \( G_k \) is a subgroup of \( S_n \). \[ \square \]

The group \((G_1, \circ)\) shown in Figure 15.8 is the stabilizer of 1 in \((S_3, \circ)\). However, \((G_2, \circ)\) shown in Figure 15.8 is not the stabilizer of 2 in \((S_3, \circ)\).

We have already mentioned that the set \( \mathbb{Z} \) of even integers is a subgroup of \((\mathbb{Z}, +)\). In fact, for every integer \( n \geq 2 \), the set \( n\mathbb{Z} = \{nk : k \in \mathbb{Z}\} \) of multiples of \( n \) is a subgroup of \((\mathbb{Z}, +)\) (see Exercise 15.31). In Chapter 9, we saw that the relation \( R \) defined on \( \mathbb{Z} \) by \( a \ R \ b \text{ if } a \equiv b \text{ (mod } n) \) is an equivalence relation. This relation can also be described in another manner, namely \( a \ R \ b \) if \( a - b \in n\mathbb{Z} \) and so \( a - b = h \) for some element \( h \in n\mathbb{Z} \) or \( a = b + h \). It turns out that this equivalence relation is a special case of a more general situation. Suppose that \( H \) is a subgroup of a group \((G, \cdot)\) and a relation \( R \) is defined on \( G \) by \( a \ R \ b \text{ if } a = bh \) for some \( h \in H \). (Note that \( b + h \) in \( \mathbb{Z} \) is replaced by \( bh \) here since the operation in \( G \) is “multiplication.”) Then this relation is also an equivalence relation.

**Theorem 15.16**

Let \( H \) be a subgroup of a group \((G, \cdot)\). The relation \( R \) defined on \( G \) by \( a \ R \ b \text{ if } a = bh \) for some \( h \in H \) is an equivalence relation.

**Proof**

First, we show that \( R \) is reflexive. Let \( a \in G \). Since \( a = ae \) (where \( e \) is the identity of \( G \) and therefore of \( H \)), \( a \ R \ a \) and so \( R \) is reflexive. Next, we show that \( R \) is symmetric. Assume that \( a \ R \ b \), where \( a, b \in G \). Then \( a = bh \) for some \( h \in H \). Since \( H \) is a group, \( h^{-1} \in H \) and so \( ah^{-1} = (bh)h^{-1} = b(hh^{-1}) = be = b \) or \( b = ah^{-1} \). Therefore, \( b \ R \ a \) and \( R \) is symmetric. Finally, we show that \( R \) is transitive. Assume that \( a \ R \ b \) and \( b \ R \ c \), where \( a, b, c \in G \). Then \( a = bh_1 \) and \( b = ch_2 \) for elements \( h_1 \) and \( h_2 \) in \( H \). Therefore, \( a = bh_1 = (ch_2)h_1 = c(h_2h_1) \). Since \( h_2, h_1 \in H \), it follows that \( h_2h_1 \in H \) as well. Thus, \( a \ R \ c \) and so \( R \) is transitive. \[ \square \]

For a subgroup \( H \) of a group \((G, \cdot)\), the equivalence relation defined in Theorem 15.16 gives rise to equivalence classes. For each element \( g \in G \), the equivalence class \([g]\) is defined by

\[
[g] = \{x \in G : x \ R \ g\} = \{x \in G : x = gh \text{ for some } h \in H\} = \{gh : h \in H\}.
\]

The set \( \{gh : h \in H\} \) is often denoted by \( gH \) and is called a left coset of \( H \) in \( G \), that is, \([g] = gH\). We saw in Chapter 9 that for an equivalence relation defined on a set \( S \), the
Proofs in Group Theory

422 Chapter 15

distinct equivalence classes form a partition of \( S \). Consequently, the equivalence relation defined in Theorem 15.16 results in a partition of \( G \) into the distinct left cosets of \( H \) in \( G \).

An important characteristic of a left coset \( gH \) of \( H \) in \( G \) is that \( gH \) and \( H \) have the same number of elements, that is, \( |gH| = |H| \). In order to see this, we show for an element \( g \in G \) that there is a bijection from \( H \) to \( gH \). Let \( \phi : H \rightarrow gH \) be defined by \( \phi(h) = gh \). First, we show that \( \phi \) is one-to-one. Assume that \( \phi(h_1) = \phi(h_2) \). Then \( gh_1 = gh_2 \). By the Left Cancellation Law, \( h_1 = h_2 \). Therefore, \( \phi \) is one-to-one. Next, we show that \( \phi \) is onto. Let \( gh \in gH \). Since \( \phi(h) = gh \), it follows that \( \phi \) is onto and so \( \phi \) is a bijection and \( |gH| = |H| \). Therefore, every two left cosets of \( H \) in \( G \) have the same number of elements.

What we have just observed provides all the information that is needed to prove a fundamental theorem of group theory, one due to Joseph-Louis Lagrange, probably the greatest French mathematician of the 18th century.

**Theorem 15.17** (Lagrange’s Theorem) If \( H \) is a subgroup of order \( m \) in a (finite) group \( G \) of order \( n \), then \( m \mid n \).

**Proof** We have already seen that the distinct left cosets of \( H \) in \( G \) form a partition of \( G \) and that every two left cosets have the same number of elements. Suppose that there are \( k \) left cosets of \( G \). Then \( n = mk \) and so \( m \mid n \).

Lagrange’s theorem first appeared in 1770–1771 in connection with the problem of solving the general polynomial of degree 5 or higher. While this theorem was not presented in this general form by Lagrange and in fact group theory had yet to be invented, it is universally referred to as Lagrange’s theorem.

We have seen that the group consisting of the nonzero elements of \( \mathbb{Z}_7 \) forms a group under multiplication, that is, \( G = \mathbb{Z}_7^* = \{[1], [2], \ldots , [6]\} \). Since \( H = \{[1], [6]\} \) is a subgroup of order 2 in \( G \), the distinct left cosets of \( H \) in \( G \) are

\[
\]

**SECTION 15.5 EXERCISES**

15.31. For an integer \( n \geq 2 \), prove that the set \( n\mathbb{Z} = \{nk : k \in \mathbb{Z}\} \) of multiples of \( n \) is a subgroup of \( (\mathbb{Z}, +) \).

15.32. Which of the following are subgroups of the given group?

(a) The subset \( N \) in \( (\mathbb{Z}, +) \)
(b) The subset \( \{[0], [2], [4]\} \) in \( (\mathbb{Z}_7, +) \)
(c) The subset \( \{[1], [2], [4]\} \) in \( (\mathbb{Z}_7^*, \cdot) \)
(d) The subset \( \{2^n : n \in \mathbb{Z}\} \) in \( (\mathbb{Q}^*, \cdot) \).

15.33. Let \( H \) and \( K \) be two subgroups of a group \( G \). Prove or disprove:

(a) \( H \cap K \) is a subgroup of \( G \).
(b) \( H \cup K \) is a subgroup of \( G \).
15.34. For each of the following subsets $H$ of $M_2^r(R)$, prove or disprove that $(H, \cdot)$ is a subgroup of $(M_2^r(R), \cdot)$.

(a) $H = \left\{ \begin{bmatrix} a & b \\ c & 0 \end{bmatrix} : a, b, c \in R, bc \neq 0 \right\}$

(b) $H = \left\{ \begin{bmatrix} a & b \\ 0 & c \end{bmatrix} : a, b, c \in R, ac \neq 0 \right\}$

15.35. Let $H = \{a + b\sqrt{3} : a, b \in Q, a \neq 0 \text{ or } b \neq 0\}$. Prove that $H$ is a subgroup of $(R^*, \cdot)$.

15.36. For $n \in N$, let $T$ be a nonempty subset of $\{1, 2, \cdots, n\}$ and define $G_T = \{a \in S_n : a(t) = t \text{ for all } t \in T\}$.

Prove that $G_T$ is a subgroup of $(S_n, \circ)$.

15.37. Recall that $M_2^r(R) = \{A \in M_2(R) : \det(A) \neq 0\}$. Let $H = \{A \in M_2^r(R) : \det(A) = 1 \text{ or } \det(A) = -1\}$.

Prove that $H$ is a subgroup of $(M_2^r(R), \cdot)$.

15.38. Let $G$ be an abelian group and let $H = \{a^2 : a \in G\}$. Prove that $H$ is a subgroup of $G$.

15.39. Let $G$ be an abelian group and let $H = \{a \in G : a^2 = e\}$. Prove that $H$ is a subgroup of $G$.

15.40. What are all the subgroups of a group of order $p$, where $p$ is a prime?

15.41. Prove or disprove: There exists a group of order 372 containing a subgroup of order 22.

15.42. Prove that a nonempty subset $H$ of a group $G$ is a subgroup of $G$ if and only if $ab^{-1} \in H$ for all $a, b \in H$.

15.43. (a) Let $(G, \ast)$ be a finite group. Prove that if $H$ is a nonempty subset of $G$ that is closed under $\ast$, then $H$ is a subgroup of $G$.

(b) Show that the result in (a) is false if $(G, \ast)$ is an infinite group.

15.44. Let $B$ be a nonempty subset of a set $A$, $S = \{f \in S_A : f(B) = B\}$ and $T = \{f \in S_A : f(b) = b \text{ for each } b \in B\}$.

(a) Prove that $(S, \circ)$ is a subgroup of $(S_A, \circ)$.

(b) Prove that $(T, \circ)$ is a subgroup of $(S, \circ)$.

15.45. A group $G$ has order 48. If there are six distinct left cosets of a subgroup $H$ in $G$, then what is the order of $H$?

15.46. For the subgroup $H = \{a_1, a_2\}$ of $(S_3, \circ)$, where $a_1 = \left( \begin{array}{ccc} 1 & 2 & 3 \\ 1 & 2 & 3 \end{array} \right)$ and $a_2 = \left( \begin{array}{ccc} 1 & 2 & 3 \\ 1 & 3 & 2 \end{array} \right)$, determine the distinct left cosets of $H$ in $G$.

15.47. For a subgroup $H$ of a group $(G, \cdot)$, let $gH$ be a left coset distinct from $H$. Prove or disprove: $g^2 \in gH$.

### 15.6 ISOMORPHIC GROUPS

Suppose that we were asked to give examples of two groups of order 3. One possible example is $(Z_3, +)$. On the other hand, we might try to construct two groups of order 3, say $G = \{a, b, c\}$ and $H = \{x, y, z\}$. Of course, we must also describe binary operations for both $G$ and $H$. Let us denote the binary operation for $G$ by $\ast$ and the binary operation for $H$ by $\circ$. So, we have two groups $(G, \ast)$ and $(H, \circ)$, both of order 3. One of the elements of $G$ is the identity for $G$ and one of the elements of $H$ is the identity for $H$. Suppose that
we decide on \( a \) as the identity for \( G \) and \( x \) as the identity for \( H \). Hence, the operations \( * \) and \( \circ \) in \( G \) and \( H \), respectively, satisfy the partial tables shown in Figure 15.12.

![Figure 15.12](image)

Because every element in each of the groups \( G \) and \( H \) must occur exactly once in every row and column in the tables shown in Figure 15.12, the complete tables for \( * \) and \( \circ \) must be those shown in Figure 15.13.

![Figure 15.13](image)

We can now readily see that in \( G \) we have \( a^{-1} = a \), \( b^{-1} = c \) and \( c^{-1} = b \), while in \( H \) we have \( x^{-1} = x \), \( y^{-1} = z \) and \( z^{-1} = y \). Verifying the associative laws requires more effort but it can be shown that the associative law holds in each case. Thus, \( (G, *) \) and \( (H, \circ) \) are both groups and we have just given examples of two groups of order 3. Or have we? There is something very similar about these two examples. They are not really two different groups at all. Indeed, the group \( (H, \circ) \) is merely a disguised form of the group \( (G, *) \). Let’s describe what we mean by this. If the elements \( a, b, c \) in \( G \) are replaced by \( x, y, z \), respectively, then we have the identical table. What’s important here is not only that \( x, y \) and \( z \) in \( H \) are playing the roles of \( a, b \) and \( c \) in \( G \) but that the operations in the two groups are doing the same thing. For example, if we multiply \( b \) and \( c \) in \( G \) (obtaining the element \( a \)), then multiplying the corresponding elements \( y \) and \( z \) in \( H \) gives us the element corresponding to \( a \), namely \( x \).

Although it may appear that this is the natural correspondence between the elements of \( G \) and the elements of \( H \), we should not be misled by the order in which the elements of these two groups are listed. For example, suppose that we consider the two groups \( (G, *) \) and \( (H, \circ) \) once again (in Figure 15.14), where the elements of \( H \) are listed in the order \( x, z, y \).

![Figure 15.14](image)

We can see that the elements \( a, b, c \) in \( G \) also correspond to \( x, z, y \), respectively. We consider the two groups \( (G, *) \) and \( (H, \circ) \) to be actually a single group, as these two
Isomorphic Groups

Isomorphic Groups

Figure 15.14 Groups \((G, *)\) and \((H, \circ)\)

groups have the same order (though the sets are different) and their operations perform the same functions (though different symbols are used for the operations). The technical term for this is that they are “isomorphic” groups (groups having the same structure).

In general, two groups \((G, *)\) and \((H, \circ)\) are isomorphic if there exists a bijective function \(\phi: G \rightarrow H\) satisfying the property

\[
\phi(a * b) = \phi(a) \circ \phi(b)
\]

for all \(a, b \in G\). Any such function \(\phi\) that satisfies the property in (15.4) is said to be operation-preserving. Thus, for \((G, *)\) and \((H, \circ)\) to be isomorphic, there must be a bijective, operation-preserving function \(\phi: G \rightarrow H\). If \(\phi\) has these properties, then \(\phi\) is called an isomorphism. If \(\phi: G \rightarrow H\) is an isomorphism, then \(\phi\) is also a bijective function. Thus, \(\phi\) has an inverse function \(\phi^{-1}: H \rightarrow G\), which is also an isomorphism (see Exercise 15.51).

For isomorphic groups \((G, *)\) and \((H, \circ)\), there are certain properties that every isomorphism from \(G\) to \(H\) must have. Two of these properties are described in the following theorem.

Theorem 15.18

Let \((G, *)\) and \((H, \circ)\) be isomorphic groups, where the identity of \(G\) is \(e\) and the identity of \(H\) is \(f\). If \(\phi: G \rightarrow H\) is an isomorphism, then

\[
(a) \quad \phi(e) = f \\
(b) \quad \phi(g^{-1}) = (\phi(g))^{-1} \text{ for all } g \in G.
\]

Proof

First, we prove (a). Let \(h \in H\). Since \(\phi\) is onto, there exists \(g \in G\) such that \(\phi(g) = h\). Since \(e * g = g * e = g\) and \(\phi\) is operation-preserving, it follows that

\[
\phi(e) \circ \phi(g) = \phi(e * g) = \phi(g) = \phi(g * e) = \phi(g) \circ \phi(e)
\]

and so

\[
\phi(e) \circ h = h \circ \phi(e) = h.
\]

This implies that \(\phi(e)\) is the identity of \(H\) and so \(\phi(e) = f\).

Next, we prove (b). Let \(g \in G\). Since \(g * g^{-1} = g^{-1} * g = e\), it follows that \(\phi(g * g^{-1}) = \phi(g^{-1} * g) = \phi(e)\) and so \(\phi(g) \circ \phi(g^{-1}) = \phi(g^{-1}) \circ \phi(g) = \phi(e) = f\). This says that \(\phi(g^{-1})\) is the inverse of \(\phi(g)\), that is, \(\phi(g^{-1}) = (\phi(g))^{-1}\). 

\[\Box\]
426 Chapter 15  Proofs in Group Theory

By definition, if two groups \((G, \ast)\) and \((H, \circ)\) are isomorphic, then there exists an isomorphism \(\phi : G \to H\). Since \(\phi\) is a bijective function, it follows that \(|G| = |H|\). Actually, it’s not surprising that isomorphic groups have the same number of elements since, when we say that \(G\) and \(H\) are isomorphic, we are technically saying that these groups are the same, except for what the elements and binary operations are called. On the other hand, consider the group tables of two groups shown in Figure 15.15. You might notice that the first group is \((\mathbb{Z}_4, +)\). The second group \(G\) is abelian, has identity \(e\) and \(x^{-1} = x\) for all \(x \in G\). In addition, of course, \(G\) has order 4. So, \(\mathbb{Z}_4\) and \(G\) both have order 4. Yet, \(\mathbb{Z}_4\) and \(G\) are not isomorphic. Suppose, however, that they are isomorphic. Then there exists an isomorphism \(\phi : \mathbb{Z}_4 \to G\). By Theorem 15.18, we know that \(\phi([0]) = e\). Let \(\phi([1]) = x \in G\). So,

\[
\phi([2]) = \phi([1] + [1]) = \phi([1]) \cdot \phi([1]) = x \cdot x = x^2 = e.
\]

Thus, \(\phi([2]) = \phi([0]) = e\) but this contradicts the fact that \(\phi\) is one-to-one. Consequently, these two groups of order 4 are not isomorphic. Therefore, if two groups have the same number of elements, they need not be isomorphic. However, it turns out that any group of order 4 is isomorphic to one of the two groups of order 4 described in Figure 15.15.

![Figure 15.15 Two groups of order 4](image)

We saw in Chapter 11 that \(|\mathbb{Z}| = |\mathbb{Q}|\) even though \(\mathbb{Z}\) is a proper subset of \(\mathbb{Q}\). However, \((\mathbb{Z}, +)\) and \((\mathbb{Q}, +)\) are not isomorphic.

**Result 15.19** The groups \((\mathbb{Z}, +)\) and \((\mathbb{Q}, +)\) are not isomorphic.

**Proof** Assume, to the contrary, that \((\mathbb{Z}, +)\) and \((\mathbb{Q}, +)\) are isomorphic. Then there exists an isomorphism \(\phi : \mathbb{Z} \to \mathbb{Q}\). Let \(\phi(1) = a \in \mathbb{Q}\). Since \(\phi(0) = 0\), it follows that \(a \neq 0\). Thus, \(a/2 \in \mathbb{Q}\) and \(a/2 \neq 0\). Since \(\phi\) is onto, there exists an integer \(n \neq 0\) such that \(\phi(n) = a/2\). Then

\[
\phi(2n) = \phi(n + n) = \phi(n) + \phi(n) = \frac{a}{2} + \frac{a}{2} = a.
\]

Since \(\phi\) is one-to-one, \(2n = 1\). However then, \(n = 1/2 \notin \mathbb{Z}\), which is a contradiction. ■

On the other hand, the set \(2\mathbb{Z}\) of even integers is a proper subset of \(\mathbb{Z}\); yet \((2\mathbb{Z}, +)\) and \((\mathbb{Z}, +)\) are isomorphic.

**Result 15.20** The groups \((2\mathbb{Z}, +)\) and \((\mathbb{Z}, +)\) are isomorphic.
Section 15.6 Exercises

15.48. Let \( H = \left\{ \begin{bmatrix} 1 & n \\ 0 & 1 \end{bmatrix} : n \in \mathbb{Z} \right\} \).

(a) Prove that \( H \) is a subgroup of \((M_2^+(\mathbb{R}), \cdot)\).

(b) Prove that the function \( f : (\mathbb{Z}, +) \to (H, \cdot) \) given by \( f(n) = \begin{bmatrix} 1 & n \\ 0 & 1 \end{bmatrix} \) is an isomorphism.

(c) Parts (a) and (b) should suggest another question to you. Ask and answer a related question.

15.49. In each of the following, determine whether the function \( f \) is an isomorphism from the first group to the second group.

(a) \( f : (\mathbb{Z}, +) \to (\mathbb{Z}, +) \) defined by \( f(n) = 2n \).

(b) \( f : (\mathbb{Z}, +) \to (\mathbb{Z}, +) \) defined by \( f(n) = n + 1 \).

(c) \( f : (\mathbb{R}, +) \to (\mathbb{R}^+, \cdot) \) defined by \( f(r) = 2r \).

(d) \( f : (M_2^+(\mathbb{R}), \cdot) \to (\mathbb{R}^+, \cdot) \) defined by \( f(A) = \det(A) \).

15.50. Obviously, \((\mathbb{R}^+, \cdot)\) and \((\mathbb{R}^+, \cdot)\) are isomorphic groups. Consider the function \( f : \mathbb{R}^+ \to \mathbb{R}^+ \) defined by \( f(r) = r^2 \) for all \( r \in \mathbb{R}^+ \). Is \( f \) an isomorphism?

15.51. Let \( (G, \ast) \) and \( (H, \circ) \) be two groups. Prove that if \( f : G \to H \) is an isomorphism, then the inverse function \( f^{-1} \) of \( f \) is an isomorphism from \( H \) to \( G \).

15.52. Let \( G, H \) and \( K \) be three groups. Prove that if \( \phi_1 : G \to H \) and \( \phi_2 : H \to K \) are isomorphisms, then the composition \( \phi_2 \circ \phi_1 : G \to K \) is an isomorphism.
Chapter 15  Proofs in Group Theory

15.53. Let \((G, \ast)\) be a group. Define a binary operation \(\circ\) on \(G\) by \(a \circ b = b \ast a\).

(a) Prove that \((G, \circ)\) is a group.

(b) Prove that \((G, \ast)\) and \((G, \circ)\) are isomorphic. [Hint: Consider the function \(\phi(g) = g^{-1}\).]

15.54. Explain why the groups \((\mathbb{Q}, +)\) and \((\mathbb{R}, +)\) are not isomorphic.

15.55. We saw in Example 15.4 that with the binary operation \(\ast\) defined on \(\mathbb{Z}\) by \(a \ast b = a + b - 1\), \((\mathbb{Z}, \ast)\) is an abelian group. Prove that \((\mathbb{Z}, \ast)\) is isomorphic to \((\mathbb{Z}, +)\).

15.56. (a) Let \(G\) and \(H\) be isomorphic groups. Prove that if \(G\) is abelian, then \(H\) is abelian.

(b) Show that the groups \((\mathbb{Z}_6, +)\) and \((S_3, \circ)\) are not isomorphic.

15.57. Let \(B = \{ \frac{n}{6} : n \in \mathbb{Z} - \{0\} \}\) and let \(A = \mathbb{R} - B\).

(a) Prove for each \(n \in \mathbb{Z}\) that the function \(f_n : A \to A\) defined by \(f_n(x) = \frac{x}{1 + nx}\) is bijective.

(b) Let \(P = \{ f_n : n \in \mathbb{Z} \}\). Prove that \((P, \circ)\) is a group of permutations on \(A\).

(c) Prove that the groups \((\mathbb{Z}, +)\) and \((P, \circ)\) are isomorphic.

15.58. Let \((G, \circ)\) and \((H, \ast)\) be groups with identities \(e\) and \(e'\), respectively. Suppose that \(f : G \to H\) is a function with the property that \(f(a \circ b) = f(a) \ast f(b)\) for all \(a, b \in G\).

(a) Let \(M = \text{range}(f)\). Prove that \((M, \ast)\) is a subgroup of \((H, \ast)\).

(b) Let \(K = \{ a \in G : f(a) = e' \}\). Prove that \((K, \circ)\) is a subgroup of \((G, \circ)\).

15.59. Let \(A = \{ \frac{m}{n} : m\) and \(n\) are odd integers, \(\gcd(m, n) = 1\) and \(n \geq 1\}\). For \(a \in A\), let \(f_a : \mathbb{R}^* \to \mathbb{R}^*\) be defined by \(f_a(x) = x^a\).

(a) Prove that \((A, \cdot)\) is a subgroup of \((\mathbb{Q}^*, \cdot)\), where the product of every two elements of \(A\) is reduced to lowest terms.

(b) Show for each \(a \in A\) that \(f_a\) is a permutation on \(\mathbb{R}^*\).

(c) Let \(F = \{ f_a : a \in A \}\). Prove that \((F, \circ)\) is a subgroup of \((S_{\mathbb{R}^*}, \circ)\).

(d) Prove that \((A, \cdot)\) and \((F, \circ)\) are isomorphic groups.

Chapter 15 Supplemental Exercises

15.60. Let \((G, \ast)\) be a group. An element \(g\) of \(G\) is an idempotent for \(\ast\) if \(g \ast g = g\). Prove that there exists exactly one idempotent in \(G\).

15.61. Let \(G\) be a group and let \(a \in G\). The set \(Z(a) = \{ g \in G : ga = ag \}\) is called the centralizer of \(a\). Prove that the centralizer of \(a\) is a subgroup of \(G\).

15.62. Let \(a, b \in \mathbb{Z}\), where \(a, b \neq 0\) and let \(H = \{ am + bn : m, n \in \mathbb{Z} \}\) be the set of all linear combinations of \(a\) and \(b\).

(a) Prove that \(H\) is a subgroup of \((\mathbb{Z}, +)\).

(b) Let \(d = \gcd(a, b)\). Prove that \(H = d\mathbb{Z}\).

15.63. Define \(\ast\) on \(\mathbb{R} - \{ 1 \}\) by \(a \ast b = a + b - ab\).

(a) Prove that \((\mathbb{R} - \{ 1 \}, \ast)\) is an abelian group.

(b) Prove that \((\mathbb{R} - \{ 1 \}, \ast)\) is isomorphic to \((\mathbb{R}^*, \cdot)\).

15.64. Let \(G\) be a group of order \(pq\), where \(p\) and \(q\) are distinct primes. What are the possible orders of a subgroup of \(G\)?

15.65. Let \(H\) be a subgroup of \((\mathbb{Z}, +)\) with at least two elements and let \(m\) be the smallest positive integer in \(H\). Prove that \(H = m\mathbb{Z}\). [Hint: Use the Division Algorithm.]
15.66. Evaluate the proposed proof of the following statement.

**Result** There exists no group containing exactly two distinct elements that do not commute.

**Proof** Assume, to the contrary, that there exists a group \( G \) containing exactly two distinct elements, say \( x \) and \( y \), that do not commute. Thus, \( xy \neq yx \). Since \( x \) and \( y \) are the only two elements of \( G \) that do not commute, \( x^{-1} \) and \( y \) do commute. Thus, \( x(x^{-1}y) = x(yx^{-1}) \). Simplifying, we have \( xy = yx \). This is a contradiction.

15.67. A group \( G \) of order \( n \geq 2 \) contains a subgroup \( H \). In a left coset decomposition of \( H \) in \( G \), the number of distinct left cosets is the same as the order of \( H \). If some left coset contains \( p \) elements, where \( p \) is a prime, then what is \( n \)?

15.68. Evaluate the proposed proof of the following statement.

**Result** There exists no abelian group containing exactly three distinct elements \( x \) such that \( x^2 = e \).

**Proof** Assume, to the contrary, that there exists an abelian group \( G \) such that \( x^2 = e \) for exactly three distinct elements \( x \) of \( G \). Certainly, \( e^2 = e \), so there are two non-identity elements \( a \) and \( b \) such that \( a^2 = b^2 = e \). Observe that \((ab)^2 = a^2b^2 = ee = e \). Hence, either \( ab = a \), \( ab = b \) or \( ab = e \), which implies, respectively, that \( b = e \), \( a = e \) or \( a = b \), producing a contradiction.

15.69. Prove or disprove the following: For each odd integer \( k \geq 3 \), there exists no abelian group containing exactly \( k \) elements \( x \) such that \( x^2 = e \).

15.70. For a function \( f : \mathbb{N} \rightarrow \mathbb{N} \), we let \( f^1 = f \) and \( f^2 = f \circ f \). More generally, for \( k \geq 2 \), the function \( f^k \) is defined recursively by \( f^k = f \circ f^{k-1} \). Thus, \( f^n : \mathbb{N} \rightarrow \mathbb{N} \) for each \( n \in \mathbb{N} \). Give an example of two elements \( f \) and \( g \) in \( S_\mathbb{N} \) such that \( f^2 = g^2 = i_\mathbb{N} \) but \((f \circ g)^m \neq i_\mathbb{N} \) for all \( m \in \mathbb{N} \).

15.71. The nonabelian group \( S_3 \) of order 6 (see Figure 15.7) has the property that it contains only one element, namely the identity \( a_1 \), that commutes with every element of \( S_3 \). Prove that no group \( G \) has the property that it contains only one element that does not commute with at least one element of \( G \).

15.72. It was mentioned in Section 15.6 that there are exactly two non-isomorphic groups of order 4. Prove this by showing that there is only one group of order 4 having four self-inverse elements and only one group of order 4 having exactly two self-inverse elements.

15.73. Prove that the relation \( R \) defined on a group \( G \) by \( a R b \) if \( b = gag^{-1} \) for some element \( g \in G \) is an equivalence relation.

15.74. (a) Prove for any element \( g \) in a finite group with identity \( e \) that \( g^n = e \) for some \( n \in \mathbb{N} \).

(b) Let \((G, \cdot)\) be an abelian group (finite or infinite) with identity \( e \). Prove that if \( H = \{ g \in G : g^n = e \text{ for some } n \in \mathbb{N} \} \), then \((H, \cdot)\) is a subgroup.
Proofs in Ring Theory

We have noted that many of the proofs we have seen thus far involve integers and their properties. This was certainly the case in Chapter 12, where we were primarily concerned with additive and multiplicative properties of integers. Many important properties of integers follow from just a very few familiar additive and multiplicative properties of integers. In particular, every three integers \(a, b, c\) satisfy the following:

\[
\begin{align*}
(1) & \quad a + b = b + a \\
(2) & \quad (a + b) + c = a + (b + c) \\
(3) & \quad a + 0 = a \\
(4) & \quad a + (-a) = 0 \\
(5) & \quad a(bc) = (ab)c \\
(6) & \quad a(b + c) = ab + ac.
\end{align*}
\]

Properties (1) – (4) tell us that the integers form an abelian group under addition, a fact we observed in Chapter 15. You can probably think of other familiar properties of integers (such as \(ab = ba\)), but let’s concentrate on the six properties listed above. We saw in Chapter 15 that some of these properties have names. For example, (1) is called the commutative law of addition, while (2) and (5) are the associative laws of addition and multiplication, respectively. Property (6) is called the distributive law. Property (3) states that the integer 0 is the identity under addition, while property (4) tells us that for an integer \(a\), the integer \(-a\) is its inverse under addition. Properties (3) and (4) in particular may seem as if they are such basic properties of the integers that they should not even be mentioned. However, it is precisely that these six properties are so basic and natural that makes them important and draws our attention to them.

A question now arises: Just what facts about the integers are consequences only of these six properties? An even more basic question is: If we have a nonempty set \(S\) of objects (not necessarily integers) for which it is possible to add and multiply every two elements of \(S\) (and in each case obtain an element of \(S\)) such that properties (1)–(6) are satisfied, then what additional properties must \(S\) possess? Of course, whatever properties that can be deduced about the elements of \(S\) will be properties of the integers as well.

In fact, this is the essence of the area of abstract algebra that we are about to encounter (and often of all mathematics). While studying a familiar set of objects, we may discover an interesting fact about this set. But what features of this set led us to this conclusion? And if any other set had these same features, does this interesting fact hold for these sets as well? We are now prepared to explore nonempty sets on which addition and multiplication have been defined that satisfy properties (1) – (6).
Addition and multiplication of integers are binary operations since each associates a unique integer with each (ordered) pair of integers. Binary operations were discussed in Chapter 15. In the current context, a nonempty set with one or more binary operations that are required to satisfy certain prescribed properties is referred to as an algebraic structure. Hence, we have already seen examples of algebraic structures. Indeed, every group (see Chapter 15) is an algebraic structure. Studying algebraic structures is fundamental to abstract algebra.

We mentioned that the familiar operations of addition and multiplication defined on the integers satisfy the six properties listed in (16.1). Other familiar sets of numbers with these operations also satisfy these six properties, including the rational numbers, the real numbers and the complex numbers. The situation is different for the irrational numbers, however, since addition and multiplication are not even binary operations. For example, \( \sqrt{2} \) and \( -\sqrt{2} \) are irrational numbers while \( \sqrt{2} \cdot \sqrt{2} = 2 \) and \( \sqrt{2} + (-\sqrt{2}) = 0 \) are not.

These and other examples suggest a general concept. A set \( R \) (this is not the symbol used for the set of real numbers) with two binary operations, one of which is called addition and denoted by + and the other called multiplication and denoted by \( \cdot \) (where we often write \( ab \) rather than \( a \cdot b \) for \( a, b \in R \)), is called a ring if it satisfies the following six properties:

R1 **Commutative Law of Addition**: \( a + b = b + a \) for all \( a, b \in R \);
R2 **Associative Law of Addition**: \( (a + b) + c = a + (b + c) \) for all \( a, b, c \in R \);
R3 **Existence of Additive Identity**: There exists an element 0 \( \in R \) such that \( a + 0 = a \) for all \( a \in R \);
R4 **Existence of Additive Inverse**: For each \( a \in R \), there exists an element \( -a \in R \) such that \( a + (-a) = 0 \);
R5 **Associative Law of Multiplication**: \( a(bc) = (ab)c \) for all \( a, b, c \in R \);
R6 **Distributive Laws**: \( a(b + c) = ab + ac \) and \( (a + b)c = ac + bc \) for all \( a, b, c \in R \).

Notice that property R3 requires the existence of at least one element in \( R \), which implies that every ring is nonempty. Recall that if \( S \) is a set with a binary operation \( * \) and \( e \in S \) is an identity for \( S \) under \( * \), then \( e * a = a * e = a \) for all \( a \in S \). Since a ring \( R \) has two binary operations and an identity element is only required for the operation of addition, we refer to an element 0 specified in property R3 as an additive identity. The notation 0 for an additive identity is chosen because the integer 0 is an additive identity in \( \mathbb{Z} \). In other words, an additive identity in a ring \( R \) has the same characteristic as the integer 0 under addition in \( \mathbb{Z} \). It is important to realize that when we refer to an additive identity 0 in a ring \( R \), we are referring only to an element in \( R \) that we are denoting by 0 and that satisfies property R3, namely, \( a + 0 = a \) for all \( a \in R \). Since property R1 holds in every ring, we also have \( 0 + a = a \).

Also, if an algebraic structure \((S, *)\) has an identity \( e \), then an element \( a \in S \) has an inverse \( b \in S \) if \( a * b = b * a = e \). Each element of a ring \( R \) is only required to have this property for the operation of addition. Thus, an inverse of an element \( a \in R \) with respect
to addition is called an **additive inverse** of \(a\). In \(\mathbb{Z}\), an additive inverse of an integer \(m\) is its negative \(-m\). For this reason, we use \(-a\) to denote an additive inverse of an element \(a\) in a ring \(R\). We must keep in mind that an element \(-a\) in \(R\) stands only for some element in \(R\) that satisfies property R4, namely, \(a + (-a) = 0\). By property R1, we also know that \((-a) + a = 0\). Since properties R1 – R4 are required of every ring \(R\), it follows that \((R, +)\) is an abelian group.

A ring with binary operations + and \(\cdot\) is commonly denoted by \((R, +, \cdot)\). However, if the two operations involved are clear, then we simply write \(R\). In particular, if we are dealing with a familiar set with standard operations of addition and multiplication (and these are the operations we are using), then we write only the symbol for that set. Thus, \(\mathbb{Z}\), \(\mathbb{Q}\), \(\mathbb{R}\) and \(\mathbb{C}\) (the complex numbers) are rings.

We now look at some other common examples of rings.

**Result 16.1** The set \(2\mathbb{Z}\) of even integers is a ring under ordinary addition and multiplication.

**Proof** First we show that ordinary addition and multiplication are binary operations on \(2\mathbb{Z}\). Let \(a, b \in 2\mathbb{Z}\). Then \(a = 2x\) and \(b = 2y\) for \(x, y \in \mathbb{Z}\). Then \(a + b = 2x + 2y = 2(x + y)\) and \(ab = (2x)(2y) = 2(2xy)\). Since \(x + y\) and \(2xy\) are integers, \(a + b\) and \(ab\) belong to \(2\mathbb{Z}\).

Since \(2\mathbb{Z} \subseteq \mathbb{Z}\) and the binary operations in \(2\mathbb{Z}\) are the same as those in \(\mathbb{Z}\), properties R1, R2, R5 and R6 are automatically satisfied. Moreover, since the integer 0 is even, \(0 \in 2\mathbb{Z}\) and so \(2\mathbb{Z}\) has an additive identity. To show that property R4 is also satisfied, let \(a \in 2\mathbb{Z}\). So \(a = 2x\), where \(x \in \mathbb{Z}\). Then \(-a = -(2x) = 2(-x)\). Since \(-x \in \mathbb{Z}\), it follows that \(-a \in 2\mathbb{Z}\). \(\blacksquare\)

**Result 16.2** The set \(\mathbb{Z}_n = \{[0], [1], [2], \cdots, [n - 1]\}\), \(n \geq 2\), of the integers modulo \(n\) is a ring under addition and multiplication defined in \(\mathbb{Z}_n\). (See Section 9.6.)

**Proof** It was indicated in Section 9.6 that both the addition and multiplication defined by \([a] + [b] = [a + b]\) and \([a] \cdot [b] = [ab]\) are well-defined and so are binary operations in \(\mathbb{Z}_n\). That properties R1, R2, R5 and R6 are satisfied depends only on the corresponding properties in the ring \(\mathbb{Z}\). For example, to see that R1 and R2 are satisfied, let \([a], [b], [c] \in \mathbb{Z}_n\). Then

\[
[a] + [b] = [a + b] = [b + a] = [b] + [a]
\]

and

\[
([a] + [b]) + [c] = [a + b] + [c] = [(a + b) + c] = [a + (b + c)] = [a] + [b + c] = [a] + ([b] + [c]).
\]

The proofs of properties R5 and R6 are similar. The element \([0]\) of \(\mathbb{Z}_n\) is an additive identity in \(\mathbb{Z}_n\), while \([-a]\) is an additive inverse for \([a]\) since \([a] + [-a] = [a + (-a)] = [0]\). \(\blacksquare\)

The ring \((\mathbb{Z}_n, +, \cdot)\) described in Result 16.2 is commonly called the **ring of integers modulo** \(n\).
Chapter 16  Proofs in Ring Theory

Result 16.3  The set $M_2(\mathbb{R})$ of $2 \times 2$ matrices over $\mathbb{R}$ is a ring under matrix addition and matrix multiplication.

**Proof** Recall that for $A = \begin{bmatrix} a & b \\ c & d \end{bmatrix}$ and $B = \begin{bmatrix} e & f \\ g & h \end{bmatrix}$ in $M_2(\mathbb{R})$, addition and multiplication are defined by

$$A + B = \begin{bmatrix} a + e & b + f \\ c + g & d + h \end{bmatrix} \quad \text{and} \quad AB = \begin{bmatrix} ae + bg & af + bh \\ ce + dg & cf + dh \end{bmatrix}.$$ 

An additive identity for $M_2(\mathbb{R})$ is the zero matrix $Z = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}$ and an additive inverse for the matrix $A$ given above is the matrix $-A = \begin{bmatrix} -a & -b \\ -c & -d \end{bmatrix}$. The verification of properties R1, R2, R5 and R6 depends only on the properties of the ring $\mathbb{R}$.

Not only is $M_2(\mathbb{R})$ a ring under matrix addition and matrix multiplication, so too is $M_n(\mathbb{R})$ for each integer $n \geq 2$.

Result 16.4  The set $\mathcal{F}_\mathbb{R} = \{ f : \mathbb{R} \to \mathbb{R} \}$ of real-valued functions with domain $\mathbb{R}$ is a ring under function addition and function multiplication.

**Proof** Recall that for $f, g \in \mathcal{F}_\mathbb{R}$, addition and multiplication are defined by

$$(f + g)(x) = f(x) + g(x) \quad \text{and} \quad (f \cdot g)(x) = f(x) \cdot g(x)$$

for all $x \in \mathbb{R}$. The proofs of properties R1, R2, R5 and R6 depend only on properties of the ring $\mathbb{R}$. For example, property R1 follows because

$$(f + g)(x) = f(x) + g(x) = g(x) + f(x) = (g + f)(x)$$

for all $x \in \mathbb{R}$ and so $f + g = g + f$, while property R5 follows because

$$((f \cdot g) \cdot h)(x) = (f \cdot g)(x) \cdot h(x) = (f(x) \cdot g(x)) \cdot h(x)$$

$$= f(x) \cdot (g(x) \cdot h(x)) = f(x) \cdot (g \cdot h)(x) = (f \cdot (g \cdot h))(x)$$

for all $x \in \mathbb{R}$ and so $(f \cdot g) \cdot h = f \cdot (g \cdot h)$.

The zero function $f_0 : \mathbb{R} \to \mathbb{R}$ defined by $f_0(x) = 0$ for all $x \in \mathbb{R}$ is an additive identity since for each $f \in \mathcal{F}_\mathbb{R}$ and all $x \in \mathbb{R}$,

$$(f + f_0)(x) = f(x) + f_0(x) = f(x) + 0 = f(x)$$

and so $f + f_0 = f$.

For $f \in \mathcal{F}_\mathbb{R}$, the function $-f \in \mathcal{F}_\mathbb{R}$ defined by $(-f)(x) = -(f(x))$ for all $x \in \mathbb{R}$ is an additive inverse for $f$ since for all $x \in \mathbb{R}$,

$$(f + (-f))(x) = f(x) + (-f)(x) = f(x) + (-f(x)) = 0 = f_0(x)$$

and so $f + (-f) = f_0$.

A less common, though useful, example of a ring is given next.
16.1 Rings

Result 16.5  The set \( \mathbb{R} \times \mathbb{R} = \mathbb{R}^2 \) is a ring under the addition \((a, b) + (c, d) = (a + c, b + d)\) and multiplication \((a, b) \cdot (c, d) = (ac, bd)\).

Before proving this result, it is important to know that we are defining a new sum \((a, b) + (c, d)\) in terms of the familiar sums \(a + c\) and \(b + d\) of two real numbers. Hence, \(+\) has two different meanings here. A similar distinction exists between the product in \(\mathbb{R}^2\) and the standard product of real numbers.

Proof of Result 16.5  Certainly the addition and multiplication defined here are binary operations on \(\mathbb{R}^2\). That \(\mathbb{R}^2\) satisfies property R1 follows because addition in \(\mathbb{R}\) is commutative. Let \((a, b), (c, d) \in \mathbb{R}^2\). Then

\[
(a, b) + (c, d) = (a + c, b + d) = (c + a, d + b) = (c, d) + (a, b).
\]

Let \((a, b) \in \mathbb{R}^2\). Observe that \((0, 0) \in \mathbb{R}^2\) and that

\[
(a, b) + (0, 0) = (a + 0, b + 0) = (a, b).
\]

Thus, \((0, 0)\) is an additive identity in \(\mathbb{R}^2\). Moreover, \((-a, -b) \in \mathbb{R}^2\) and

\[
(a, b) + (-a, -b) = (a + (-a), b + (-b)) = (0, 0).
\]

Hence \((-a, -b)\) is an additive inverse of \((a, b)\) and properties R3 and R4 hold.

We only verify one of the distributive laws R6 for a ring as the argument for the remaining law is similar. Again, let \((a, b), (c, d), (e, f) \in \mathbb{R}^2\). Applying the distributive law for addition and multiplication in \(\mathbb{R}\), we have

\[
(a, b)[(c, d) + (e, f)] = (a, b)(c + e, d + f) = (a(c + e), b(d + f))
= (ac + ae, bd + bf) = (ac, bd) + (ae, bf)
= (a, b)(c, d) + (a, b)(e, f),
\]

establishing this distributive law in \(\mathbb{R}^2\).

The associative properties R2 and R5 can be established in \(\mathbb{R}^2\) in a similar manner.  

Next we show that familiar sets, under unfamiliar binary operations, need not be rings.

Example 16.6  For \(a, b \in \mathbb{R}\), define addition \(\oplus\) and multiplication \(\odot\) by

\[
a \oplus b = a + b - 1 \quad \text{and} \quad a \odot b = ab,
\]

where the operations indicated in \(a + b - 1\) and \(ab\) are ordinary addition, subtraction and multiplication. Then \((\mathbb{R}, \oplus, \odot)\) is not a ring.

Solution  It was shown in Example 15.4 that the binary operation \(\oplus\) satisfies properties R1–R4, that is, \((\mathbb{R}, \oplus)\) is an abelian group. Because \(\odot\) is ordinary multiplication, property R5 holds as well. However, property R6 is not satisfied since for \(a = b = c = 0\),

\[
a \odot (b \oplus c) = 0 \odot (-1) = 0 \quad \text{and} \quad (a \odot b) \oplus (a \odot c) = 0 \oplus 0 = -1.
\]

Thus, \(0 \odot (0 \oplus 0) \neq (0 \odot 0) \oplus (0 \odot 0)\). Therefore, \((\mathbb{R}, \oplus, \odot)\) is not a ring.  
°
6  Chapter 16  Proofs in Ring Theory

Let’s see what happens when ordinary addition and multiplication of real numbers are reversed.

Example 16.7  The set $\mathbb{R}$ of real numbers is not a ring when addition $\ast$ is defined as ordinary multiplication and multiplication $\circ$ is defined as ordinary addition.

Solution  We denote ordinary addition of real numbers by $+$ and ordinary multiplication by $\cdot$ (though we write $a \cdot b$ as $ab$, as usual). We show that a distributive law fails in $(\mathbb{R}, \ast, \circ)$.

Let $a = b = c = -1$. Then

$$a \circ (b \ast c) = a + (bc) = (-1) + (-1)(-1) = (-1) + 1 = 0,$$

while

$$(a \circ b) \ast (a \circ c) = (a + b)(a + c) = [(-1) + (-1)][(-1) + (-1)] = (-2)(-2) = 4.$$

Hence, $(-1) \circ ((-1) \ast (-1)) \neq ((-1) \circ (-1)) \ast ((-1) \circ (-1))$ and so property R6 is not satisfied. Therefore, $(\mathbb{R}, \ast, \circ)$ is not a ring.

Some rings satisfy properties beyond the six properties required of all rings. We have already mentioned that the integers satisfy the familiar property: $ab = ba$ for all $a, b \in \mathbb{Z}$. This, of course, is the commutative law of multiplication. Rings are not required to have this property. However, when they do, we give these rings a special name. A ring $(R, +, \cdot)$ is called a commutative ring if it satisfies

R7  Commutative Law of Multiplication: $ab = ba$ for all $a, b \in R$.

A ring $(R, +, \cdot)$ that does not satisfy the Commutative Law of Multiplication is called a noncommutative ring. While the rings $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, $2\mathbb{Z}$, $\mathbb{Z}_n$, $\mathbb{F}_p$ and $\mathbb{R}^2$ are commutative, the ring $M_2(\mathbb{R})$ is noncommutative. For example, if we let

$$A = \begin{bmatrix} 0 & 0 \\ 2 & 0 \end{bmatrix} \text{ and } B = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix},$$

then

$$AB = \begin{bmatrix} 0 & 0 \\ 0 & 4 \end{bmatrix} \neq \begin{bmatrix} 4 & 0 \\ 0 & 0 \end{bmatrix} = BA.$$

Another property that $\mathbb{Z}$ possesses, which is basic, yet important, is that it contains an integer $e$ with the property that $a \cdot e = e \cdot a = a$ for every integer $a$. Of course, 1 has this property in $\mathbb{Z}$. In general, a ring $(R, +, \cdot)$ is called a ring with unity (or a ring with multiplicative identity) if it satisfies

R8  Existence of Multiplicative Identity: There exists an element $1 \in R$ such that $a \cdot 1 = 1 \cdot a = a$ for all $a \in R$.

If $(R, +, \cdot)$ has an element 1 satisfying property R8, then 1 is called a unity for $R$. Again, we stress that much care is needed here. When we write 1, we mean only an element of $R$ that satisfies property R8, namely, $a \cdot 1 = 1 \cdot a = a$ for all $a \in R$. It does not imply that 1 is the integer 1. Indeed, $R$ itself could be a ring with unity that contains no integers whatsoever. Also, if $R$ is a commutative ring, then to show that some element $1 \in R$ is a unity requires only to show that $a \cdot 1 = a$ for all $a \in R$ since $a \cdot 1 = 1 \cdot a$ for all $a \in R$. 
The rings \( \mathbb{Z}, \mathbb{Q}, \mathbb{R}, \mathbb{C}, \mathbb{Z}_n, \mathbb{F}_R \) and \( \mathbb{R}^2 \) are rings with unity. The number 1 is a unity for \( \mathbb{Z}, \mathbb{Q} \) and \( \mathbb{R} \) and \( 1 = 1 + 0i \) is a unity for \( \mathbb{C} \). The element \([1]\) is a unity for \( \mathbb{Z}_n \), while the constant function \( f_1: \mathbb{R} \to \mathbb{R} \) defined by \( f_1(x) = 1 \) for all \( x \in \mathbb{R} \) is a unity for \( \mathbb{F}_R \). Furthermore, the ordered pair \((1, 1)\) is a unity for \( \mathbb{R}^2 \). The noncommutative ring \( M_2(\mathbb{R}) \) has a unity as well. Indeed, the \( 2 \times 2 \) identity matrix

\[ I = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \]

is a unity for \( M_2(\mathbb{R}) \) since

\[ \begin{bmatrix} a & b \\ c & d \end{bmatrix} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} a & b \\ c & d \end{bmatrix} = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \]

for all \( a, b, c, d \in \mathbb{R} \). On the other hand, not all rings have a unity. In particular, the ring \( 2\mathbb{Z} \) of even integers does not have a unity since the only integer \( e \) such that \( e \cdot a = a \) for every integer \( a \) is \( e = 1 \) but \( 1 \notin 2\mathbb{Z} \).

### 16.2 ELEMENTARY PROPERTIES OF RINGS

Despite the fact that there are many different examples of rings of various types, there are properties that all rings have in common. Necessarily, of course, any such properties are consequences of the six defining properties of a ring. We now present some properties that all rings share, beginning with the uniqueness of certain types of elements in rings.

The definition of a ring \( R \) guarantees that it contains an additive identity, that is, an element \( 0 \) such that \( a + 0 = a \) for all \( a \in R \). Although the definition does not specify that there is only one such element, there is, in fact, only one. Also, the definition of \( R \) states that for each \( a \in R \), there is an element \( -a \in R \) such that \( a + (-a) = 0 \). Again, there is no indication that each element of \( R \) has only one additive inverse, but, in fact, this is the case. Actually, these are consequences of the fact that \( R \) is a group under addition (see Theorem 15.9), but we verify these facts here.

**Theorem 16.8** Let \( R \) be a ring. Then

(i) \( R \) has a unique additive identity, and

(ii) each element in \( R \) has a unique additive inverse.

**Proof** We first verify (i). Suppose that both \( 0 \) and \( 0' \) are additive identities for \( R \). Since \( 0 \) is an additive identity, \( 0' + 0 = 0' \). Also, since \( 0' \) is an additive identity, \( 0 + 0' = 0 \). It then follows by the commutative law that \( 0' = 0' + 0 = 0 + 0' = 0 \) and so \( 0' = 0 \). Therefore, there is only one additive identity in \( R \) and (i) holds.

We now verify (ii). Suppose that \( -x \) and \( x' \) are both additive inverses for the element \( x \in R \). Then \( x + (-x) = 0 \) and \( x + x' = 0 \). Hence,

\[-x = -x + 0 = -x + (x + x') = (-x + x) + x' = (x + (-x)) + x' = 0 + x' = x'.\]

So, each element in \( R \) has a unique additive inverse.
8 Chapter 16 Proofs in Ring Theory

PROOF ANALYSIS Let’s revisit the proof of the uniqueness of additive inverses in Theorem 16.8 to see how this proof may have been constructed. We know that \( x + (-x) = 0 \) and \( x + x' = 0 \). Since \( x + (-x) = 0 = x + x' \), it follows, by adding \(-x\) to the equal elements \( x + (-x) \) and \( x + x' \), that

\[
-x + (x + (-x)) = -x + (x + x'). \tag{16.2}
\]

The left side of (16.2) is \(-x + 0 = -x\). Our goal was to show that \(-x = x'\), so this suggests starting with \(-x = -x + 0 = -x + (x + x')\). The remainder of the proof then follows quite naturally. The resulting proof given in Theorem 16.8 is certainly much clearer than giving a list of equalities, with no accompanying explanations:

\[
x + (-x) = x + x' \\
-x + (x + (-x)) = -x + (x + x') \\
(-x + x) + (-x) = (-x + x) + x' \\
0 + (-x) = 0 + x' \\
-x = x'. \]

In view of Theorem 16.8, we can now refer to the additive identity of a ring and the additive inverse of an element in a ring. The additive identity of a ring \( R \) is called the zero element of \( R \).

Not only are the additive identity and the additive inverse of every element in a ring \( R \) unique, but if \( R \) has a unity, then this element is unique as well.

Theorem 16.9 If \( R \) is a ring with unity, then \( R \) has a unique unity.

Proof Let 1 and 1' be unities in \( R \). Since 1 is a unity, \( 1 \cdot 1' = 1' \cdot 1 = 1' \); while since 1' is a unity, \( 1 \cdot 1' = 1' \cdot 1 = 1 \). Therefore, \( 1 = 1 \cdot 1' = 1' \).

A basic fact concerning rings allows us to simplify certain algebraic expressions. Although the next theorem is a consequence of the fact that \( R \) is an abelian group under addition (see Theorem 15.7), we provide a proof of this theorem.

Theorem 16.10 (Cancellation Law of Addition) If \( a, b \) and \( c \) are elements in a ring \((R, +, \cdot)\) such that \( a + b = a + c \), then \( b = c \).

Proof Observe that

\[
b = 0 + b = [(-a) + a] + b = (-a) + (a + b) \\
= (-a) + (a + c) = [(-a) + a] + c = 0 + c = c.
\]

Therefore, the Cancellation Law of Addition holds in \((R, +, \cdot)\).

PROOF ANALYSIS Another version of the preceding proof begins with \( a + b = a + c \) (that is, \( a + b \) and \( a + c \) represent the same element in \( R \)). If the additive inverse \(-a\) of \( a \) is now added to this element, we obtain

\[-a + (a + b) = -a + (a + c).
\]
By the associative law,
\[ (-a + a) + b = (-a + a) + c; \]
so \( 0 + b = 0 + c \) and thus \( b = c \).

We have seen that the zero element \( 0 \) in a ring \( R \) has the property that \( 0 + 0 = 0 \). Hence, \( R \) contains an element \( c \) such that \( c + c = c \), namely, \( c = 0 \). However, as an immediate consequence of the Cancellation Law of Addition, no other element of \( R \) has this property.

**Corollary 16.11** Let \((R, +, \cdot)\) be a ring. If \( c \) is an element of \( R \) such that \( c + c = c \), then \( c = 0 \).

**Proof** Since \( c + c = c \), we also have \( c + c = c + 0 \). Now, canceling \( c \), it follows by Theorem 16.10 that \( c = 0 \).

Although the defining property of the zero element of a ring \((R, +, \cdot)\) concerns only one of the two operations, namely addition, it has a property involving multiplication that is probably expected.

**Theorem 16.12** For every element \( a \) in a ring \((R, +, \cdot)\),
\[ a \cdot 0 = 0 \cdot a = 0. \]

**Proof** Since the proofs that \( a \cdot 0 = 0 \) and \( 0 \cdot a = 0 \) are similar, we only verify the first of these. Observe that
\[ a \cdot 0 = a \cdot (0 + 0) = a \cdot 0 + a \cdot 0. \]
The result now follows from Corollary 16.11 (where \( c = a \cdot 0 \)).

We now turn our attention to properties of rings involving additive inverses. At times, a very simple argument for some fact can be given by recognizing that \(-a\) represents the unique element which when added to \( a \) results in 0. Two examples of this appear in the following theorem.

**Theorem 16.13** Let \((R, +, \cdot)\) be a ring and let \( a, b \in R \). Then
\[ (i) \quad -(-a) = a \]
\[ (ii) \quad \text{if} \ a = -b, \ \text{then} \ b = -a. \]

**Proof** Since \( a + (-a) = 0 \), it follows that \( a \) is the additive inverse of \(-a\), that is, \( a = -(-a) \). This verifies \((i)\).

To establish \((ii)\), let \( a = -b \). Hence, \( a \) is the additive inverse of \( b \) and so \( a + b = 0 \). This, however, implies that \( b \) is the additive inverse of \( a \) and so \( b = -a \).

We now consider some results concerning the product of two elements in a ring, at least one of which is an additive inverse. Since the additive inverse is an element that is defined only in terms of addition, it would seem natural that any property concerning
10 Chapter 16  Proofs in Ring Theory

such an element that involves multiplication must be a consequence of the distributive laws. (This is exactly what occurred in Theorem 16.12.)

Theorem 16.14  Let \((R, +, \cdot)\) be a ring and let \(a, b \in R\). Then
\[
(-a)b = a(-b) = -(ab).
\]

\textbf{Proof}  To show that \((-a)b = -(ab)\), it suffices to verify that \((-a)b\) is the additive inverse of \(ab\). This can be accomplished by showing that \(ab + (-a)b = 0\). Observe that
\[
ab + (-a)b = [a + (-a)]b = 0 \cdot b = 0.
\]
A proof that \(a(-b) = -(ab)\) is similar. 

\textbf{Corollary 16.15}  Let \((R, +, \cdot)\) be a ring and let \(a, b \in R\). Then
\[
(-a)(-b) = ab.
\]

\textbf{Proof}  By Theorem 16.14, \((-a)(-b) = a[-(-b)]\), and by Theorem 16.13, \(-(-b) = b\). Thus, \((-a)(-b) = ab\). 

In the ring \(\mathbb{Z}\) of integers, we know that if \(a, b \in \mathbb{Z}\), then \(a + (-b) = a - b\). We follow this convention in an arbitrary ring. If \((R, +, \cdot)\) is a ring and \(a, b \in R\), then we define the subtraction of \(b\) from \(a\) as \(a - b = a + (-b)\). In particular, if \(a = b\) in \(R\), then we arrive at the seemingly obvious fact that \(a - b = b - b = b + (-b) = 0\).

The next result gives a basic fact concerning subtraction.

\textbf{Result 16.16}  Let \((R, +, \cdot)\) be a ring and let \(a, b, c \in R\). Then \(a(b - c) = ab - ac\).

\textbf{Proof}  Observe that \(a(b - c) = a[b + (-c)] = ab + a(-c)\). By Theorem 16.14, \(a(-c) = -(ac)\), so \(a(b - c) = ab + [-(-ac)] = ab - ac\).

16.3 SUBRINGS

We have seen that the subset \(2\mathbb{Z}\) of \(\mathbb{Z}\) is a ring when the operations of addition and multiplication used in \(2\mathbb{Z}\) are the same as those of \(\mathbb{Z}\). Since \(\mathbb{Z}\) is already a ring, we found that it was relatively easy to prove that \(2\mathbb{Z}\) is a ring. We saw that \(2\mathbb{Z}\) inherits the properties R1, R2, R5 and R6 of a ring from \(\mathbb{Z}\). What we didn’t know automatically, and therefore had to verify, was that \(2\mathbb{Z}\) is closed under addition and multiplication, that the zero element of \(\mathbb{Z}\) is also in \(2\mathbb{Z}\) and that each element of \(2\mathbb{Z}\) has an additive inverse in \(2\mathbb{Z}\). In general, then, it is much easier to prove that a subset \(S\) of a known ring \(R\) is a ring under the same operations defined on \(R\). This observation leads us to an important concept in the study of rings.

Let \(R\) be a ring. If \(S\) is a subset of \(R\) such that \(S\) is a ring under the same operations defined on \(R\), then \(S\) is called a subring of \(R\). If \(R\) contains at least two elements, then \(R\) contains at least two subrings, namely \(R\) itself and the “zero subring” \([0]\). We now state exactly what properties need to be verified to show that a subset of a known ring \(R\) is a subring of \(R\).
Theorem 16.17  (The Subring Test) A nonempty subset $S$ of a ring $R$ is a subring of $R$ if and only if $S$ is closed under subtraction and multiplication.

Proof  If $S$ is a subring of $R$, then certainly $S$ is closed under subtraction and multiplication. For the converse, let $R$ be a ring and $S$ a nonempty subset of $R$ that is closed under subtraction and multiplication. We show that $S$ itself is a ring. Since $S \neq \emptyset$, there is some element $s \in S$. Because $S$ is closed under subtraction, $s - s = 0 \in S$, that is, the zero element of $R$ belongs to $S$ and so property R3 holds. Now let $a \in S$. Again, since $S$ is closed under subtraction, $0 - a = 0 + (-a) = -a \in S$ and so property R4 holds. This implies that the additive inverse of an element of $S$ also belongs to $S$. For $a, b \in S$, we know that $-b \in S$ and so $a - (-b) = a + [(-b)] = a + b \in S$. Hence, $S$ is closed under addition as well.

Now it remains to show that addition is commutative, that addition and multiplication are associative and that distributive laws hold, namely, properties R1, R2, R5 and R6 hold in $S$. But all these properties are inherited from $R$ and so hold in $S$ as well. □

Consequently, to show that a subset $S$ of a ring $R$ is a subring, we need only show that $S$ is nonempty and that $S$ is closed under subtraction and multiplication. We now illustrate how the Subring Test is used by presenting several examples, beginning with a new proof that $2\mathbb{Z}$ is a ring under ordinary addition and multiplication.

Result 16.18  The subset $2\mathbb{Z}$ of even integers is a subring of $\mathbb{Z}$.

Proof  Since 0 is an even integer, $2\mathbb{Z}$ is nonempty. Let $a, b \in 2\mathbb{Z}$. Then $a = 2x$ and $b = 2y$, where $x, y \in \mathbb{Z}$. Observe that $a - b = 2x - 2y = 2(x - y)$ and $ab = (2x)(2y) = 2(2xy)$. Since $x - y$ and $2xy$ are integers, $a - b$ and $ab$ belong to $2\mathbb{Z}$. By the Subring Test, $2\mathbb{Z}$ is a subring of $\mathbb{Z}$. □

Result 16.19  The subset $R \times \{0\} = \{(x, 0) : x \in R\}$ of the ring $R \times R$ is a subring of $R \times R$.

Proof  Since $(0, 0) \in R \times \{0\}$, the set $R \times \{0\}$ is nonempty. Let $a, b \in R \times \{0\}$. Then $a = (x, 0)$ and $b = (y, 0)$ for some $x, y \in R$. Thus, $a - b = (x, 0) - (y, 0) = (x - y, 0 - 0) = (x - y, 0) \in R \times \{0\}$ and $a \cdot b = (x, 0) \cdot (y, 0) = (xy, 0) \in R \times \{0\}$. By the Subring Test, $R \times \{0\}$ is a subring of $R \times R$. □

The next example concerns a subring of the ring of complex numbers. A complex number of the form $a + bi$, where $a, b \in \mathbb{Z}$ and $i = \sqrt{-1}$, is called a Gaussian integer.

Result 16.20  The set $G = \{a + bi : a, b \in \mathbb{Z}\}$ of Gaussian integers is a subring of the ring $\mathbb{C}$ of complex numbers.

Proof  Since $0 = 0 + 0i \in G$, the set $G$ is nonempty. Let $x, y \in G$. Then $x = a + bi$ and $y = c + di$, where $a, b, c, d \in \mathbb{Z}$. Observe that

$$x - y = (a + bi) - (c + di) = (a - c) + (b - d)i$$
and

$$xy = (a + bi)(c + di) = (ac - bd) + (ad + bc)i.$$  

Since $a - c$, $b - d$, $ac - bd$ and $ad + bc$ are integers, $x - y$ and $xy$ are Gaussian integers. By the Subring Test, $G$ is a subring of $\mathbb{C}$.

The elements that belong to two subrings of a ring $R$ also produce a subring of $R$.

**Result 16.21** If $S_1$ and $S_2$ are subrings of a ring $R$, then $S_1 \cap S_2$ is also a subring of $R$.

**Proof** Since $0 \in S_1$ and $0 \in S_2$, it follows that $0 \in S_1 \cap S_2$ and so $S_1 \cap S_2$ is nonempty. Let $a, b \in S_1 \cap S_2$. Then $a, b \in S_i$ for $i = 1, 2$. Since $S_1$ and $S_2$ are subrings of $R$, it follows that $a - b \in S_i$ and $ab \in S_i$ for $i = 1, 2$. Hence, $a - b \in S_1 \cap S_2$ and $ab \in S_1 \cap S_2$. Therefore, by the Subring Test, $S_1 \cap S_2$ is a subring of $R$.

### 16.4 INTEGRAL DOMAINS

Properties possessed by the integers have led us to the concept of a ring as well as two special kinds of rings, namely commutative rings and rings with unity. We have seen that if $R$ is a ring, then $a \cdot 0 = 0 \cdot a = 0$ for every $a \in R$. This property can be stated in another way:

Let $a, b \in R$. If $a = 0$ or $b = 0$, then $a \cdot b = 0$.  \(16.3\)

Of course, the converse of $16.3$ also holds in the ring $\mathbb{Z}$:

Let $a, b \in \mathbb{Z}$. If $a \cdot b = 0$, then $a = 0$ or $b = 0$. \(16.4\)

The implication (16.4) also holds in the ring of real numbers. Indeed, (16.4) is the critical property of real numbers needed for solving many equations. For example, if $(x - 3)(x + 2) = 0$, where $x \in \mathbb{R}$, then $x = 3$ or $x = -2$. This leads us to another important concept.

A nonzero element $a$ in a ring $R$ is called a **zero divisor** of $R$ if there exists a nonzero element $b$ in $R$ such that either $ab = 0$ or $ba = 0$. Of course, in this case, $b$ is a zero divisor of $R$ as well.

Certainly then, the rings $\mathbb{Z}$ and $\mathbb{R}$ have no zero divisors. Furthermore, $2\mathbb{Z}$, $\mathbb{Q}$ and $\mathbb{C}$ are also rings possessing no zero divisors. There are, however, some well-known rings that do have zero divisors. In $\mathbb{Z}_6$, we have seen that $[2][3] = [6] = [0]$. Since $[2] \neq [0]$ and $[3] \neq [0]$, it follows that $[2]$ and $[3]$ are zero divisors in $\mathbb{Z}_6$. The element $[4]$ is also a zero divisor in $\mathbb{Z}_6$ since $[4][3] = [0]$.

For the sets $\mathbb{Q}$ and $\mathbb{I}$ of rational and irrational numbers, respectively, consider the functions $f$ and $g$ in $\mathcal{F}_R$ defined as:

$$f(x) = \begin{cases} 1 & \text{if } x \in \mathbb{Q} \\ 0 & \text{if } x \in \mathbb{I} \end{cases} \quad g(x) = \begin{cases} 0 & \text{if } x \in \mathbb{Q} \\ 1 & \text{if } x \in \mathbb{I} \end{cases}$$

Then $(f \cdot g)(x) = f(x) \cdot g(x) = 0 = f_0(x)$ for all $x \in \mathbb{R}$. Hence, $f \cdot g = f_0$, the zero element of $\mathcal{F}_R$, but $f \neq f_0$ and $g \neq f_0$. So, $f$ and $g$ are zero divisors in $\mathcal{F}_R$. 
In $M_2(\mathbb{R})$, let

$$A = \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}.$$ 

Then

$$AB = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \quad \text{while} \quad BA = \begin{bmatrix} 0 & 2 \\ 0 & 0 \end{bmatrix}.$$

Hence, $A$ and $B$ are zero divisors in the noncommutative ring $M_2(\mathbb{R})$.

From what we have seen, it is not all that uncommon for a ring $R$ to contain nonzero elements whose product is the zero element of $R$. Thus, it is useful to distinguish those rings that contain zero divisors from those that do not. Before proceeding further though, we need to address one special kind of ring. A ring $R$ is called trivial if it contains only one element – necessarily, then, the zero element. That is, $R$ is trivial if $R = \{0\}$. If $R$ is nontrivial, then it contains at least two elements and consequently at least one nonzero element. If $R$ is a trivial ring, then certainly $a \cdot 0 = 0 \cdot a = a$ for all $a \in R$ since $a = 0$ is the only element of $R$. Therefore, if $R$ is trivial, then it contains a unity (namely 0). Obviously, a trivial ring is commutative as well. On the other hand, if $R$ is a nontrivial ring with unity, then it cannot occur that the unity and zero elements are the same.

**Theorem 16.22** If $R$ is a nontrivial ring with unity 1, then $1 \neq 0$.

**Proof** Assume, to the contrary, that $1 = 0$. Since $R$ is a nontrivial ring, there is an element $a \in R$ such that $a \neq 0$. However, then

$$a = a \cdot 1 = a \cdot 0 = 0,$$

which is a contradiction.

A nontrivial commutative ring with unity that contains no zero divisors is called an **integral domain**. Therefore, all of the rings $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$ and $\mathbb{C}$ are integral domains.

Not all commutative rings with unity are integral domains, however. For example, we saw that $[2]$ and $[3]$ are zero divisors in $\mathbb{Z}_6$. We also saw that $F_2$ possesses zero divisors. Moreover, since $(0, 1) \cdot (1, 0) = (0, 0)$ in $\mathbb{R}^2$, it follows that $(0, 1)$ and $(1, 0)$ are zero divisors in $\mathbb{R}^2$. Therefore, although each of $\mathbb{Z}_6$, $F_2$ and $\mathbb{R}^2$ is a commutative ring with unity, none is an integral domain.

Since an integral domain is required to be a commutative ring with unity, $2\mathbb{Z}$ is not an integral domain despite the fact that it is both commutative and contains no zero divisors, as it does not contain a unity.

We have seen that every ring satisfies the Cancellation Law of Addition. For multiplication, the situation can be quite different. There are two possible cancellation laws in this case.

**Cancellation Laws of Multiplication** Let $R$ be a ring and let $a, b, c \in R$.

1. If $ab = ac$, where $a \neq 0$, then $b = c$.
2. If $ac = bc$, where $c \neq 0$, then $a = b$. 

14 Chapter 16 Proofs in Ring Theory

Of course, if $R$ is a commutative ring, then (1) and (2) say the same thing. In a noncommutative ring, (1) is referred to as the Left Cancellation Law of Multiplication and (2) as the Right Cancellation Law of Multiplication. In the ring $\mathbb{Z}_6$, $[3] \cdot [2] = [3] \cdot [4]$ but $[2] \neq [4]$. So, the Cancellation Laws of Multiplication fail to hold in $\mathbb{Z}_6$. The Cancellation Laws of Multiplication never fail to hold in rings without zero divisors, however.

**Theorem 16.23** Let $R$ be a ring. Then the Cancellation Laws of Multiplication hold in $R$ if and only if $R$ contains no zero divisors.

**Proof** Assume first that $R$ is a ring without zero divisors. We only verify the Left Cancellation Law (1) since the proof of (2) is similar. Let $a, b, c \in R$, where $a \neq 0$ and $ab = ac$. Since $ab = ac$, it follows that $ab + (-ac) = ac + (-ac)$ and so $ab - ac = 0$. Thus, $a(b - c) = 0$. Since $R$ contains no zero divisors and $a \neq 0$, it follows that $b - c = 0$ and so $b = c$.

For the converse, assume that $R$ is a ring in which the Cancellation Laws of Multiplication hold. We show that $R$ contains no zero divisors. Let $a, b \in R$ such that $ab = 0$. We show that $a = 0$ or $b = 0$. If $a = 0$, then we have the desired result. So, we may assume that $a \neq 0$. Hence, $a \cdot b = 0 = a \cdot 0$ and so $a \cdot b = a \cdot 0$. By the (Left) Cancellation Law of Multiplication, the element $a$ can be canceled in $a \cdot b = a \cdot 0$, arriving at $b = 0$. Thus, $R$ has no zero divisors.

Since a ring $R$ satisfying the Cancellation Laws of Multiplication is equivalent to $R$ containing no zero divisors, we have an immediate consequence of Theorem 16.23.

**Corollary 16.24** Let $R$ be a nontrivial commutative ring with unity. Then $R$ is an integral domain if and only if the Cancellation Law of Multiplication holds in $R$.

While $\mathbb{Z}_6$ is not an integral domain, it is not difficult to show that $\mathbb{Z}_5$ is. This can be seen by constructing the multiplication table for $\mathbb{Z}_5$ in the same manner as was done for $\mathbb{Z}_6$ in Figure 9.2 of Chapter 9. Consequently, some rings $\mathbb{Z}_n$ are integral domains while others are not. You might have seen a difference between $\mathbb{Z}_6$ and $\mathbb{Z}_5$ already, namely, 5 is prime and 6 is not. We are about to see that this is the key observation. In the proof of the next theorem, we will use the fact that if $a$ and $b$ are integers and $p$ is a prime such that $p \mid ab$, then $p \mid a$ or $p \mid b$. (This theorem is discussed in detail in Chapter 12. In particular, see Corollary 12.14.)

**Theorem 16.25** For an integer $n \geq 2$, the ring $\mathbb{Z}_n$ is an integral domain if and only if $n$ is a prime.

**Proof** First, we show that if $\mathbb{Z}_n$ is an integral domain, then $n$ is a prime. Assume, to the contrary, that there exists an integral domain $\mathbb{Z}_n$ such that $n$ is not a prime. Then $n = ab$ for some integers $a$ and $b$ with $1 < a < n$ and $1 < b < n$. Thus, $[a] \neq [0]$ and $[b] \neq [0]$ in $\mathbb{Z}_n$. On the other hand, $[a][b] = [ab] = [n] = [0]$ in $\mathbb{Z}_n$. Hence, $[a]$ and $[b]$ are zero divisors in $\mathbb{Z}_n$, contradicting our assumption that $\mathbb{Z}_n$ is an integral domain.

For the converse, assume that $n$ is a prime. We show that $\mathbb{Z}_n$ is an integral domain. Certainly, $\mathbb{Z}_n$ is a nontrivial commutative ring with unity. So, it remains only to show that $\mathbb{Z}_n$ has no zero divisors. Let $[a], [b] \in \mathbb{Z}_n$ such that $[a] \cdot [b] = [0]$. Then
$[a] \cdot [b] = [ab] = [0]$, which implies that $ab \equiv 0 \pmod{n}$. Therefore, $n \mid ab$. Since $n$ is a prime, it follows by Corollary 12.14 that $n \mid a$ or $n \mid b$; so $[a] = [0]$ or $[b] = [0]$. Thus, $\mathbb{Z}_n$ contains no zero divisors.

16.5 Fields

Initially, we saw that many fundamental properties of integers are shared by other algebraic structures. This led us to the concept of rings. Among the many rings we encountered are $\mathbb{Z}$, $\mathbb{Z}_2$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, $\mathbb{Z}_n$, $\mathbb{F}_p$ and $M_2(\mathbb{R})$. However, only some of these are commutative rings with unity, namely, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$, $\mathbb{Z}_n$ and $\mathbb{F}_p$; and only some of these are integral domains, namely, $\mathbb{Z}$, $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{Z}_p$, where $p$ is a prime. There is a property that $\mathbb{Q}$, $\mathbb{R}$, $\mathbb{C}$ and $\mathbb{Z}_p$ possess that $\mathbb{Z}$ does not, however, which will finally allow us to distinguish $\mathbb{Z}$ from these rings.

Let $a$ be a nonzero integer. Unless $a$ is 1 or $-1$, there is no integer $b$ such that $ab = 1$. On the other hand, if $a$ is a nonzero rational number, then there is always a rational number $b$ such that $ab = 1$. Indeed, $b = 1/a \in \mathbb{Q}$ has this property.

This discussion leads us to another concept. Let $R$ be a ring with unity 1. A nonzero element $a$ of $R$ is called a **unit** if there is some element $b$ in $R$ such that $ab = ba = 1$. In this case, $b$ is called a **multiplicative inverse** of $a$. (Of course, $b$ is also a unit with multiplicative inverse $a$.) We must take care to distinguish between the terms “unit” and “unity” in a ring $R$. A unity in $R$ is an element $1 \in R$ such that $1 \cdot 1 = 1$. Indeed, $1 = 1/a \in \mathbb{Q}$ has this property.

A nontrivial commutative ring with unity in which every nonzero element is a unit is called a **field**. In addition to $\mathbb{Q}$ and $\mathbb{R}$, the ring $\mathbb{C}$ of complex numbers is a field.

**Theorem 16.26** Let $R$ be a nontrivial ring with unity. Then each unit in $R$ has a unique multiplicative inverse.

**Proof** Let $a$ be a unit in $R$ and suppose that $b$ and $c$ are multiplicative inverses of $a$. Hence, $ab = ba = 1$ and $ac = ca = 1$. It then follows that

$$b = b \cdot 1 = b(ac) = (ba)c = 1 \cdot c = c.$$

Therefore, $a$ has a unique multiplicative inverse.

The ring $\mathbb{C}$ of complex numbers is a field.
Chapter 16  Proofs in Ring Theory

Proof  We have already noted that \( C \) is a commutative ring with unity, so we are only required to show that every nonzero complex number is a unit. Let \( x \) be a nonzero complex number. Hence, \( x = a + bi \), where \( a, b \in \mathbb{R} \) and either \( a \neq 0 \) or \( b \neq 0 \). Thus, \( a^2 + b^2 \neq 0 \). We show that there exists a complex number \( y = c + di \), where \( c, d \in \mathbb{R} \), such that \( xy = 1 = 1 + 0i \). Let \( c = \frac{a}{a^2 + b^2} \) and \( d = \frac{-b}{a^2 + b^2} \) and observe that

\[
xy = (a + bi)(c + di) = (a + bi)
\left(\frac{a}{a^2 + b^2} + \frac{-b}{a^2 + b^2}i\right)
= \frac{1}{a^2 + b^2}(a + bi)(a - bi) = \frac{1}{a^2 + b^2}(a^2 + b^2)
= \frac{a^2 + b^2}{a^2 + b^2} = 1 = 1 + 0i.
\]

Hence, \( x \) has a multiplicative inverse, namely, \( x^{-1} = \frac{a}{a^2 + b^2} + \frac{-b}{a^2 + b^2}i \). ■

Proof Analysis  In the proof of the preceding result, for the nonzero complex number \( x = a + bi \), how did we know to choose \( y = c + di \) so that \( xy = 1 = 1 + 0i \)? That is, how did we know what the multiplicative inverse of \( x \) was? Actually, that was not so difficult.

Since \( xy = (a + bi)(c + di) = 1 + 0i \), it follows that \( (ac - bd) + (ad + bc)i = 1 + 0i \). Hence,

\[
ac - bd = 1 \tag{16.5}
\]

and

\[
ad + bc = 0. \tag{16.6}
\]

Multiplying equation (16.5) by \( a \), equation (16.6) by \( b \) and adding, we obtain

\[
(a^2 + b^2)c = a; \tag{16.7}
\]

while multiplying equation (16.5) by \( -b \), equation (16.6) by \( a \) and adding, we obtain

\[
(a^2 + b^2)d = -b. \tag{16.8}
\]

Solving (16.7) for \( c \) and (16.8) for \( d \), we find that

\[
c = \frac{a}{a^2 + b^2} \text{ and } d = \frac{-b}{a^2 + b^2}.
\]

Hence, \( \frac{a}{a^2 + b^2} + \frac{-b}{a^2 + b^2}i \) is the logical choice for \( x^{-1} \). That \( c + di \) is actually \( x^{-1} \) was, of course, verified in the proof of Result 16.27. ■

Theorem 16.28  Every field is an integral domain.

Proof  Let \( F \) be a field. To verify that \( F \) is also an integral domain, we need only show that \( F \) contains no zero divisors. Let \( a \) be a nonzero element of \( F \) and let \( b \in F \) such that \( ab = 0 \). Then \( 0 = a^{-1} \cdot 0 = a^{-1}(ab) = (a^{-1}a) \cdot b = 1b = b \). Since \( b = 0 \), it follows that \( a \) is not a zero divisor. ■
Exercises for Chapter 16

Certainly, the converse of Theorem 16.28 is not true since \( \mathbb{Z} \) is an integral domain that is not a field. However, under a certain restriction, an integral domain is a field as well.

**Theorem 16.29**  Every finite integral domain is a field.

**Proof**  Let \( D \) be a finite integral domain, say \( D = \{a_1, a_2, \ldots, a_n\} \). To show that \( D \) is a field, we need only show that every nonzero element of \( D \) has a multiplicative inverse. Let \( a \in D \), where \( a \neq 0 \), and consider the elements \( aa_1, aa_2, \ldots, aa_n \). If \( aa_i = aa_j \), where \( 1 \leq i \leq n \) and \( 1 \leq j \leq n \), then \( a_i = a_j \) by the Cancellation Law of Multiplication. This implies that the elements \( aa_1, aa_2, \ldots, aa_n \) are distinct and are, in fact, all \( n \) elements of \( D \). Thus, one of these elements is 1 and so \( aa_k = 1 \) for some integer \( k \) with \( 1 \leq k \leq n \). Hence, \( a_k = a^{-1} \) and \( a \) has a multiplicative inverse. \( \blacksquare \)

We have seen in Theorem 16.25 that \( \mathbb{Z}_n \) is an integral domain if and only if \( n \) is a prime. Theorem 16.29 now gives us the following result.

**Corollary 16.30**  The ring \( \mathbb{Z}_n \) is a field if and only if \( n \) is prime.

**EXERCISES FOR CHAPTER 16**

16.1 Verify that each of the following is a ring by showing that (1) the indicated addition and multiplication are binary operations and (2) the required six properties are satisfied. (You may assume that both \( \mathbb{Z} \) and \( \mathbb{R} \) are rings under ordinary addition and multiplication.)

(a) The set \( k\mathbb{Z} \), where \( k \in \mathbb{Z} \) and \( k \geq 2 \), under ordinary addition and multiplication.

(b) The set \( \mathbb{Z}[\sqrt{2}] = \{a + b\sqrt{2} : a, b \in \mathbb{Z}\} \) under ordinary addition and multiplication.

16.2 Verify that each of the following is not a ring.

(a) The set \( \mathcal{F}_\mathbb{R} \) under function addition and function composition.

(b) The set \( \mathbb{Z} \) under the addition defined by \( a \ast b = a \) and ordinary multiplication.

(c) The set \( \mathbb{Z} \) under ordinary addition and the multiplication defined by \( a \ast b = a \).

(d) The set \( \mathbb{Z} \) under the addition defined by \( a \ast b = \min\{a, b\} \) and ordinary multiplication.

(e) The set \( \mathbb{Z} \) under ordinary addition and the multiplication defined by \( a \ast b = \min\{a, b\} \).

16.3 For a given set \( S \) and binary operations \( \ast \) and \( \circ \), determine whether \( (S, \ast, \circ) \) is a ring.

(a) \( S = \mathbb{R}, a \ast b = a + b + 1, a \circ b = ab \).

(b) \( S = \mathbb{R}^+, \) the set of positive real numbers, \( a \ast b = ab \) and \( a \circ b = a^b \).

16.4 Let \( a \) be an element in a ring \( (\mathbb{R}, +, \cdot) \). Complete the proof of Theorem 16.12 by proving that \( 0 \cdot a = 0 \).

16.5 Let \( a \) and \( b \) be elements in a ring \( (\mathbb{R}, +, \cdot) \). Complete the proof of Theorem 16.14 by proving that \( a(-b) = -(ab) \).

16.6 Let \( \mathbb{R} \) be a ring with unity 1. Use Theorem 16.14 to prove that \( (-1)a = -a \) for all \( a \in \mathbb{R} \).

16.7 Let \( (\mathbb{R}, +, \cdot) \) be a ring with the property that \( a^2 = a \cdot a = a \) for every \( a \in \mathbb{R} \).

(a) Prove that every element in \( \mathbb{R} \) is its own additive inverse, that is, prove that \( -a = a \) for every \( a \in \mathbb{R} \). [Hint: Consider \( (a + a)^2 \).]

(b) Prove that \( \mathbb{R} \) is a commutative ring. [Hint: Consider \( (a + b)^2 \).]
18 Chapter 16  Proofs in Ring Theory

16.8 Does there exist an example of a nontrivial ring \((R, +, \cdot)\) such that addition and multiplication in \(R\) are the same, namely, \(a + b = ab\) for all \(a, b \in R\)? Justify your answer.

16.9 Verify that each of the following subsets is a subring of the given ring.
(a) \(S = \{a \begin{bmatrix} 0 \\ b \end{bmatrix} : a, b \in R\} \) in the ring \(M_2(R)\).
(b) \(S = \{a + b\sqrt{2} + c\sqrt{4} : a, b, c \in Q\} \) in the ring \(R\).

16.10 Prove that the subset \(S = \{0\}, [2], [4]\) is a subring of \(Z_6\).

16.11 Recall that a Gaussian integer is a complex number of the type \(a + bi\), where \(a, b \in Z\) and \(i = \sqrt{-1}\), and that the set \(G\) of Gaussian integers is a subring of the ring \(C\) of complex numbers. Define an even Gaussian integer to be a complex number of the type \(a + bi\), where \(a, b \in 2Z\). Is the set \(2G\) of even Gaussian integers a subring of \(G\)? Justify your answer.

16.12 By Result 16.21, if \(S_1\) and \(S_2\) are subrings of a ring \(R\), then \(S_1 \cap S_2\) is a subring of \(R\). Both \(2Z\) and \(3Z\) are subrings of the ring \(Z\). Give a simple description of the subring \(2Z \cap 3Z\) in \(Z\). Justify your answer.

16.13 Let \(S = \{a \begin{bmatrix} b \\ 0 \end{bmatrix} : a, b \in R\}\).
(a) Prove that \(S\) is a subring of \(M_2(R)\).
(b) Prove that there is an element \(E \in S\) such that \(EA = A\) for all \(A \in S\), but there is an element \(C \in S\) such that \(CE \neq C\).
(c) Prove that \(S\) does not possess a unity.

16.15 Define multiplication \(\circ\) on \(2Z\) by \(a \circ b = ab/2\). Prove that \((2Z, +, \circ)\) is an integral domain, where + is ordinary addition.

16.16 Let \(R\) be a commutative ring with unity.
(a) Prove that a unit of \(R\) is not a zero divisor in \(R\).
(b) Determine whether the converse of (a) is true.
(c) Prove that if \(R\) is a finite ring and \(a\) is not a zero divisor of \(R\), then \(a\) has a multiplicative inverse in \(R\).

16.17 Define addition \(\ast\) and multiplication \(\circ\) on \(Z\) as follows:
\[a \ast b = a + b - 1\quad \text{and}\quad a \circ b = a + b + ab.\]
Prove or disprove: The algebraic structure \((Z, \ast, \circ)\) is a ring.

16.18 Show that \(Z[\sqrt{2}] = \{a + b\sqrt{2} : a, b \in Z\}\) is not a field.

16.19 Give an example of a ring that is not a field but has a subring that is a field.

16.20 Let \(R\) be a nontrivial commutative ring with unity. Prove that \(R\) is a field if and only if for every \(a, b \in R\) with \(a \neq 0\), the equation \(ax = b\) has a solution \(x \in R\).

16.21 Prove that \(Q[i] = \{a + bi : a, b \in Q\}\) is a field.

16.22 Let \((F, +, \cdot)\) be a field and let \(a, b \in F\) with \(a \neq 0\). Show that the equation \(a \cdot x = b\) has a unique solution \(x \in F\).

16.23 Give examples of the following (if they exist):
(a) a finite ring
(b) an infinite ring
(c) a noncommutative finite ring
(d) a noncommutative infinite ring
Exercises for Chapter 16

(e) a ring with unity  
(f) a ring without unity  
(g) a noncommutative ring with unity  
(h) a noncommutative ring without unity  
(i) a ring that is not an integral domain  
(j) a finite integral domain  
(k) an infinite integral domain  
(ℓ) an integral domain that is not a field  
(m) a finite field  
(n) an infinite field

16.24 For the following statement $S$ and proposed proof, either (1) $S$ is true and the proof is correct, (2) $S$ is true and the proof is incorrect or (3) $S$ is false and the proof is incorrect. Explain which of these occurs.

$S$: Let $A = \{n \in \mathbb{N} : n = 0\}$. Then $A$ is a subring of $(\mathbb{Z}, +, \cdot)$.

**Proof** Let $a, b \in S$. Then $a = 0$ and $b = 0$. Since $a - b = 0 - 0 = 0 \in A$ and $a \cdot b = 0 \cdot 0 = 0 \in A$, it follows that $A$ is closed under subtraction and multiplication. By the Subring Test, $(A, +, \cdot)$ is a subring of $(\mathbb{Z}, +, \cdot)$.

16.25 For the following statement $S$ and proposed proof, either (1) $S$ is true and the proof is correct, (2) $S$ is true and the proof is incorrect or (3) $S$ is false and the proof is incorrect. Explain which of these occurs.

$S$: Let $R$ be a ring with unity containing at least two elements and let

$$R' = \{a \in R : a - r \text{ is a unit for each } r \in R\}.$$  

Then $R'$ is a subring of $R$.

**Proof** Let $a, b \in R'$. First, consider $a - b$ and $r \in R$. Then $(a - b) - r = a - (b + r)$. Since $a \in R'$ and $b + r \in R$, it follows that $(a - b) - r$ is a unit and so $a - b \in R'$. Next, consider $ab$ and $r' \in R$. Then $ab - r' = a - (ab + r')$. Since $a \in R'$ and $a - ab + r' \in R$, it follows that $ab - r'$ is a unit. Thus, $ab \in R'$. By the Subring Test, $R'$ is a subring of $R$.  

Proofs in Linear Algebra

A topic you may very well have studied in geometry, calculus or physics is vectors. You might recall vectors both in the plane $\mathbb{R}^2 = \mathbb{R} \times \mathbb{R}$ and in 3-space $\mathbb{R}^3 = \mathbb{R} \times \mathbb{R} \times \mathbb{R}$. Often one thinks of a vector as a directed line segment from the origin to some other point. Examples of these (both in the plane and in 3-space) are shown in Figure 17.1.

Figure 17.1 Vectors in the plane and 3-space

The vector $\mathbf{u}$ in the plane (it is customary to print vectors in bold) shown in Figure 17.1(a) can be expressed as $\mathbf{u} = (4, 3)$, while the vector $\mathbf{v}$ in 3-space shown in Figure 17.1(b) can be expressed as $\mathbf{v} = (2, 3, 4)$. The vectors $\mathbf{i} = (1, 0)$ and $\mathbf{j} = (0, 1)$ in the plane and $\mathbf{i} = (1, 0, 0), \mathbf{j} = (0, 1, 0)$ and $\mathbf{k} = (0, 0, 1)$ in 3-space will be of special interest to us.
2 Chapter 17 Proofs in Linear Algebra

17.1 PROPERTIES OF VECTORS IN 3-SPACE

One important feature of vectors is that they can be added (to produce another vector), while another is that a vector can be multiplied by an element of some set, usually a real number (again to produce another vector). In this context, these elements are called scalars. Let’s focus on vectors in 3-space for the present. Let \( \mathbf{u} = (a_1, b_1, c_1) \) and \( \mathbf{v} = (a_2, b_2, c_2) \), where \( a_i, b_i, c_i \) (\( i = 1, 2 \)) are real numbers. The sum of \( \mathbf{u} \) and \( \mathbf{v} \) is defined by

\[
\mathbf{u} + \mathbf{v} = (a_1 + a_2, b_1 + b_2, c_1 + c_2)
\]

and the scalar multiple of \( \mathbf{u} \) by a scalar (real number) \( \alpha \) is defined by

\[
\alpha \mathbf{u} = (\alpha a_1, \alpha b_1, \alpha c_1).
\]

From these definitions, it follows that

\[
\mathbf{u} = (a_1, b_1, c_1) = (a_1, 0, 0) + (0, b_1, 0) + (0, 0, c_1) = a_1 \mathbf{i} + b_1 \mathbf{j} + c_1 \mathbf{k}.
\]

That is, it is possible to express a vector \( \mathbf{u} \) in 3-space in terms of the vectors \( \mathbf{i}, \mathbf{j} \) and \( \mathbf{k} \) in 3-space (called a linear combination of \( \mathbf{i}, \mathbf{j} \) and \( \mathbf{k} \)). Listed below are eight simple, yet fundamental, properties that follow from these definitions of vector addition and scalar multiplication in \( \mathbb{R}^3 \):

1. \( \mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u} \) for all \( \mathbf{u}, \mathbf{v} \in \mathbb{R}^3 \).
2. \( (\mathbf{u} + \mathbf{v}) + \mathbf{w} = \mathbf{u} + (\mathbf{v} + \mathbf{w}) \) for all \( \mathbf{u}, \mathbf{v}, \mathbf{w} \in \mathbb{R}^3 \).
3. For \( \mathbf{z} = (0, 0, 0) \), \( \mathbf{u} + \mathbf{z} = \mathbf{u} \) for all \( \mathbf{u} \in \mathbb{R}^3 \).
4. For each \( \mathbf{u} \in \mathbb{R}^3 \), there exists a vector in \( \mathbb{R}^3 \) which we denote by \( -\mathbf{u} \) such that \( \mathbf{u} + (-\mathbf{u}) = \mathbf{z} = (0, 0, 0) \).
5. \( \alpha (\mathbf{u} + \mathbf{v}) = \alpha \mathbf{u} + \alpha \mathbf{v} \) for all \( \mathbf{u}, \mathbf{v} \in \mathbb{R}^3 \) and all \( \alpha \in \mathbb{R} \).
6. \( (\alpha + \beta) \mathbf{u} = \alpha \mathbf{u} + \beta \mathbf{u} \) for all \( \alpha, \beta \in \mathbb{R} \) and all \( \mathbf{u} \in \mathbb{R}^3 \).
7. \( (\alpha \beta) \mathbf{u} = \alpha (\beta \mathbf{u}) \) for all \( \alpha, \beta \in \mathbb{R} \) and all \( \mathbf{u} \in \mathbb{R}^3 \).
8. \( 1 \mathbf{u} = \mathbf{u} \) for all \( \mathbf{u} \in \mathbb{R}^3 \).

These properties are rather straightforward to verify, as we illustrate with properties 1, 4 and 6. To verify property 1, observe that

\[
\mathbf{u} + \mathbf{v} = (a_1, a_2, a_3) + (b_1, b_2, b_3) = (a_1 + b_1, a_2 + b_2, a_3 + b_3) = (b_1 + a_1, b_2 + a_2, b_3 + a_3) = \mathbf{v} + \mathbf{u}.
\]

Here, we used only the definition of addition of vectors in \( \mathbb{R}^3 \) and the fact that addition of real numbers is commutative.

To verify property 4, we begin with a vector \( \mathbf{v} = (b_1, b_2, b_3) \in \mathbb{R}^3 \) and show that there is some vector in \( \mathbb{R}^3 \), which we denote by \( -\mathbf{v} \), such that \( \mathbf{v} + (-\mathbf{v}) = \mathbf{z} = (0, 0, 0) \). There is an obvious choice for \( -\mathbf{v} \), however, namely \( (-b_1, -b_2, -b_3) \). Observe that

\[
\mathbf{v} + (-\mathbf{v}) = (b_1, b_2, b_3) + (-b_1, -b_2, -b_3) = (b_1 + (-b_1), b_2 + (-b_2), b_3 + (-b_3)) = (0, 0, 0).
\]
Hence, \(-v = (-b_1, -b_2, -b_3)\) has the desired property. We note also that, according to the definition of scalar multiplication in \(\mathbb{R}^3\),
\[
(-1)v = ((-1)b_1, (-1)b_2, (-1)b_3) = (-b_1, -b_2, -b_3) = -v.
\]

We will revisit this observation later.

To establish property 6, observe that
\[
(\alpha + \beta)u = (\alpha + \beta)(a_1, b_1, c_1)
\]
\[
= ((\alpha + \beta)a_1, (\alpha + \beta)b_1, (\alpha + \beta)c_1)
\]
\[
= (\alpha a_1 + \beta a_1, \alpha b_1 + \beta b_1, \alpha c_1 + \beta c_1)
\]
\[
= (\alpha a_1, \alpha b_1, \alpha c_1) + (\beta a_1, \beta b_1, \beta c_1)
\]
\[
= \alpha(a_1, b_1, c_1) + \beta(a_1, b_1, c_1)
\]
\[
= \alpha u + \beta u.
\]

Thus, showing that \((\alpha + \beta)u = \alpha u + \beta u\) also depends only on some familiar properties of addition and multiplication of real numbers. Vectors in the plane can be added and multiplied by scalars in the expected manner and, in fact, satisfy properties 1–8 as well.

### 17.2 Vector Spaces

In addition to vectors in the plane and 3-space, there are other mathematical objects that can be added and multiplied by scalars so that properties 1–8 are satisfied. Indeed, these objects provide a generalization of vectors in the plane and 3-space. For this reason, these more abstract objects are referred to as vectors as well. The study of vectors is a major topic in the area of mathematics called linear algebra.

A set \(V\) every two elements of which can be added (that is, if \(u, v \in V\), then \(u + v\) is a unique element of \(V\)) and each element of which can be multiplied by any real number (that is, if \(\alpha \in \mathbb{R}\) and \(v \in V\), then \(\alpha v\) is a unique element in \(V\)) is called a vector space (in fact, a vector space over \(\mathbb{R}\)) if it satisfies the following eight properties:

1. \(u + v = v + u\) for all \(u, v \in V\). (Commutative Property)
2. \((u + v) + w = u + (v + w)\) for all \(u, v, w \in V\). (Associative Property)
3. There exists an element \(z \in V\) such that \(v + z = v\) for all \(v \in V\).
4. For each \(v \in V\), there exists an element \(-v \in V\) such that \(v + (-v) = z\).
5. \(\alpha(u + v) = \alpha u + \alpha v\) for all \(\alpha \in \mathbb{R}\) and all \(u, v \in V\).
6. \((\alpha + \beta)v = \alpha v + \beta v\) for all \(\alpha, \beta \in \mathbb{R}\) and all \(v \in V\).
7. \((\alpha \beta)v = \alpha(\beta v)\) for all \(\alpha, \beta \in \mathbb{R}\) and all \(v \in V\).
8. \(1v = v\) for all \(v \in V\).

The elements of such a set \(V\) are called vectors and the real numbers in this context are called scalars. Hence, if \(u, v \in V\) and \(\alpha, \beta \in \mathbb{R}\), then both \(\alpha u\) and \(\beta v\) belong to \(V\). Therefore, \(\alpha u + \beta v \in V\). The vector \(\alpha u + \beta v\) is called a linear combination of \(u\) and \(v\).

We can also discuss linear combinations of more than two vectors. Let \(u, v, w\) be three vectors in \(V\) and let \(\alpha, \beta, \gamma\) be three scalars (real numbers). Therefore, \(\alpha u, \beta v\) and \(\gamma w\)
are three vectors in $V$ and $\alpha u + \beta v + \gamma w$ is a linear combination of $u$, $v$ and $w$. We’ve now encountered a familiar situation in mathematics. Since addition in $V$ is only defined for two vectors, what exactly is meant by $\alpha u + \beta v + \gamma w$? There are two obvious interpretations of $\alpha u + \beta v + \gamma w$, namely, $(\alpha u + \beta v) + \gamma w$ (where $\alpha u$ and $\beta v$ are added first, producing the vector $\alpha u + \beta v$, which is then added to $\gamma w$) and $\alpha u + (\beta v + \gamma w)$. However, property 2 (the associative law of addition of vectors) guarantees that both interpretations give us the same vector and, consequently, there is nothing ambiguous about writing $\alpha u + \beta v + \gamma w$ without parentheses. In fact, if $v_1, v_2, \ldots, v_n \in V$ and $\alpha_1, \alpha_2, \ldots, \alpha_n \in \mathbb{R}$, then $\alpha_1 v_1 + \alpha_2 v_2 + \cdots + \alpha_n v_n$ is a linear combination of the vectors $v_1, v_2, \ldots, v_n$.

The element $z \in V$ described in property 3 (and used in property 4) is called a zero vector and an element $-v$ in property 4 is called a negative of $v$. By the commutative property, we also know that $z + v = v$ and $(-v) + v = z$ for every vector $v \in V$. Since $V$ satisfies properties 1–4, the set $V$ forms an abelian group under addition (see Chapter 15).

Although we have only defined a vector space over the set $\mathbb{R}$ of real numbers (and this is all we will deal with), it is not always required that the scalars be real numbers. Indeed, there are certain situations when complex numbers are not only suitable scalars (since addition in $\mathbb{C}$ is all we will deal with), it is not always required that the scalars be real numbers. (Real and complex numbers are discussed in some detail in the online Chapter 18.) Other possibilities exist as well.

Of course, we have seen two examples of vector spaces, namely, $\mathbb{R}^2$ and $\mathbb{R}^3$ (with addition and scalar multiplication defined previously). More generally, $n$-space $\mathbb{R}^n = \mathbb{R} \times \mathbb{R} \times \cdots \times \mathbb{R}$ ($n$ factors) is a vector space where addition of two vectors $u = (a_1, a_2, \ldots, a_n)$ and $v = (b_1, b_2, \ldots, b_n)$ is defined, as expected, by

$$u + v = (a_1 + b_1, a_2 + b_2, \ldots, a_n + b_n)$$

and scalar multiplication $\alpha u$, where $\alpha \in \mathbb{R}$, is defined by

$$\alpha u = (\alpha a_1, \alpha a_2, \ldots, \alpha a_n).$$

We now describe two vector spaces of a very different nature. Recall that $\mathcal{F}_\mathbb{R}$ is the set of all functions from $\mathbb{R}$ to $\mathbb{R}$, that is,

$$\mathcal{F}_\mathbb{R} = \{f : f : \mathbb{R} \to \mathbb{R}\}.$$  

Therefore, the well-known trigonometric function $f_1 : \mathbb{R} \to \mathbb{R}$ defined by $f_1(x) = \sin x$ for all $x \in \mathbb{R}$ belongs to $\mathcal{F}_\mathbb{R}$. The function $f_2 : \mathbb{R} \to \mathbb{R}$ defined by $f_2(x) = 3x + x/(x^2 + 1)$ for all $x \in \mathbb{R}$ also belongs to $\mathcal{F}_\mathbb{R}$.

For $f, g \in \mathcal{F}_\mathbb{R}$ and a scalar (real number) $\alpha$, addition and scalar multiplication are defined by

$$(f + g)(x) = f(x) + g(x) \quad \text{for all } x \in \mathbb{R},$$

$$(\alpha f)(x) = \alpha(f(x)) \quad \text{for all } x \in \mathbb{R}.$$  

For the functions $f_1$ and $f_2$ defined above,

$$(f_1 + f_2)(x) = \sin x + 3x + \frac{x}{x^2 + 1} \quad \text{and} \quad (5f_2)(x) = 15x + \frac{5x}{x^2 + 1}.$$  

Under these definitions of addition and scalar multiplication, $\mathcal{F}_\mathbb{R}$ is a vector space, the verification of which depends only on ordinary addition and multiplication of real numbers. As an illustration, we verify that $\mathcal{F}_\mathbb{R}$ satisfies properties 2–5 of a vector space.
First we verify property 2. Let \( f, g, h \in \mathcal{F}_\mathbb{R} \). Then
\[
(f + g) + h(x) = (f + g)(x) + h(x) = (f(x) + g(x)) + h(x) = f(x) + (g + h)(x)
\]
for all \( x \in \mathbb{R} \). Therefore, \((f + g) + h = f + (g + h)\).

Second we show that \( \mathcal{F}_\mathbb{R} \) satisfies property 3 of a vector space. Define the (constant) function \( f_0 : \mathbb{R} \to \mathbb{R} \) by \( f_0(x) = 0 \) for all \( x \in \mathbb{R} \). We show that \( f_0 \) is a zero vector for \( \mathcal{F}_\mathbb{R} \). For \( f \in \mathcal{F}_\mathbb{R} \),
\[
(f + f_0)(x) = f(x) + f_0(x) = f(x) + 0 = f(x)
\]
for all \( x \in \mathbb{R} \). Therefore, \( f + f_0 = f \). The function \( f_0 \) is called the **zero function** in \( \mathcal{F}_\mathbb{R} \).

Next, we show that \( \mathcal{F}_\mathbb{R} \) satisfies property 4 of a vector space. For each function \( f \in \mathcal{F}_\mathbb{R} \), define the function \(-f : \mathbb{R} \to \mathbb{R}\) by \((-f)(x) = -(f(x))\) for all \( x \in \mathbb{R} \). Since
\[
(f + (-f))(x) = f(x) + (-f)(x) = f(x) + (-f(x)) = 0 = f_0(x)
\]
for all \( x \in \mathbb{R} \), it follows that \( f + (-f) = f_0 \) and so \(-f\) is a negative of \( f \).

Finally, we show that \( \mathcal{F}_\mathbb{R} \) satisfies property 5 of a vector space. Let \( f, g \in \mathcal{F}_\mathbb{R} \) and \( \alpha \in \mathbb{R} \). Then, for each \( x \in \mathbb{R} \),
\[
(\alpha(f + g))(x) = \alpha((f + g)(x)) = \alpha(f(x) + g(x)) = \alpha f(x) + \alpha g(x) = (\alpha f)(x) + (\alpha g)(x) = (\alpha f + \alpha g)(x)
\]
and so \( \alpha(f + g) = \alpha f + \alpha g \).

We now consider a special class of real-valued functions defined on \( \mathbb{R} \). These functions are important in many areas of mathematics, not only linear algebra. A function \( p : \mathbb{R} \to \mathbb{R} \) is called a **polynomial function** (actually a polynomial function over \( \mathbb{R} \)) if
\[
p(x) = a_0 + a_1 x + \cdots + a_n x^n
\]
for all \( x \in \mathbb{R} \), where \( n \) is a nonnegative integer and \( a_0, a_1, \ldots, a_n \) are real numbers. The expression \( p(x) \) itself is called a polynomial in \( x \). You may recall that if \( a_n \neq 0 \), then \( n \) is the **degree** of \( p(x) \). The zero function \( f_0 \) is a polynomial function. It is assigned no degree, however. We denote the set of all polynomial functions over \( \mathbb{R} \) by \( \mathbb{R}[x] \). Hence, \( \mathbb{R}[x] \subseteq \mathcal{F}_\mathbb{R} \).

Let \( f, g \in \mathbb{R}[x] \) and let \( \alpha \in \mathbb{R} \). Then
\[
(f + g)(x) = f(x) + g(x) = (a_0 + b_0 + (a_1 + b_1)x + \cdots + (a_n + b_n)x^n + b_{n+1}x^{n+1} + \cdots + b_m x^m),
\]
and the scalar multiple \( \alpha f \) of \( f \) by \( \alpha \) is the polynomial function defined by
\[
(\alpha f)(x) = \alpha f(x) = (\alpha a_0 + \alpha a_1 x + \cdots + (\alpha a_n) x^n).
\]
These definitions are, of course, exactly the same as the sum of two elements of \( \mathcal{F}_\mathbb{R} \) and the scalar product of an element of \( \mathcal{F}_\mathbb{R} \) by a real number.
Actually, \( R[x] \) is itself a vector space over \( R \) under the addition and scalar multiplication we have just defined. For example, let \( f, g \in R[x] \). Since \( R[x] \subseteq F_R \) and addition in \( R[x] \) is defined exactly the same as in \( F_R \), it follows that \( f + g = g + f \), that is, property 1 of a vector space is satisfied. By the same reasoning, property 2 and properties 5–8 are satisfied as well. The zero function \( f_0 \) is in \( R[x] \) and we know that \( f + f_0 = f \) for all \( f \in F_R \). Hence, \( p + f_0 = p \) for all \( p \in R[x] \). So, \( f_0 \) is a zero vector for \( R[x] \). For \( f \in R[x] \) defined by \( f(x) = a_0 + a_1 x + \cdots + a_n x^n \), we know that \(-f\) is given by \((-f)(x) = -(f(x)) = (-a_0) + (-a_1)x + \cdots + (-a_n)x^n \). Thus, \(-f \in R[x] \) is a negative of \( f \). Hence, properties 3 and 4 are satisfied as well and so \( R[x] \) is a vector space over \( R \).

17.3 MATRICES

Among the best known and most important examples of vector spaces are those concerning matrices. A rectangular array of real numbers is called a matrix. The plural of “matrix” is “matrices.” (In general, a matrix need not be an array of real numbers — it can be a rectangular array of elements from any prescribed set. However, we will deal only with real numbers.) Thus, a matrix has \( m \) rows and \( n \) columns for some pair \( m, n \) of positive integers and contains \( mn \) real numbers, each of which is located in some row \( i \) and column \( j \) for integers \( i \) and \( j \) with \( 1 \leq i \leq m \) and \( 1 \leq j \leq n \). A matrix with \( m \) rows and \( n \) columns is said to have size \( m \times n \) and is called an \( m \times n \) matrix (read as “\( m \) by \( n \) matrix”). Hence,

\[
B = \begin{bmatrix}
1 & \sqrt{2} & -3/2 \\
0 & -8 & 4
\end{bmatrix}
\]

is a \( 2 \times 3 \) matrix, while

\[
C = \begin{bmatrix}
4 & 1 & 9 \\
0 & 3 & 2 \\
7 & -1 & 1
\end{bmatrix}
\]

is a \( 3 \times 3 \) matrix. A general \( m \times n \) matrix \( A \) is commonly written as

\[
A = \begin{bmatrix}
a_{11} & a_{12} & \ldots & a_{1n} \\
a_{21} & a_{22} & \ldots & a_{2n} \\
\vdots & \vdots & \ddots & \vdots \\
a_{m1} & a_{m2} & \ldots & a_{mn}
\end{bmatrix}
\]

Therefore, \( a_{ij} \) represents the element located in row \( i \) and column \( j \) of \( A \). This is referred to as the \((i, j)\)-entry of \( A \). In fact, it is convenient shorthand notation to represent the matrix \( A \) by \( [a_{ij}] \) and to write \( A = [a_{ij}] \). The \( i \)th row of \( A \) is \( [a_{i1} \ a_{i2} \ldots a_{in}] \) and the \( j \)th column is

\[
\begin{bmatrix}
a_{1j} \\
a_{2j} \\
\vdots \\
a_{mj}
\end{bmatrix}
\]
For two matrices to be equal, they must have the same size. Furthermore, two \( m \times n \) matrices \( A = [a_{ij}] \) and \( B = [b_{ij}] \) are equal, written as \( A = B \), if \( a_{ij} = b_{ij} \) for all integers \( i \) and \( j \) with \( 1 \leq i \leq m \) and \( 1 \leq j \leq n \). That is, \( A = B \) if \( A \) and \( B \) have the same size and corresponding entries are equal. Hence, in order for
\[
A = \begin{bmatrix} 2 & x & -3 \\ 1/2 & 4 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 2 & 4/5 & -3 \\ y & 4 & 0 \end{bmatrix}
\]
to be equal, we must have \( x = 4/5 \) and \( y = 1/2 \).

For positive integers \( m \) and \( n \), let \( M_{mn}[\mathbb{R}] \) denote the set of all \( m \times n \) matrices whose entries are real numbers. If \( m = n \), then the matrices are called square matrices. The set of all \( m \times m \) (square) matrices whose entries are real numbers is also denoted by \( M_{mm}[\mathbb{R}] \).

We now define addition and scalar multiplication in \( M_{mn}[\mathbb{R}] \). Let \( A, B \in M_{mn}[\mathbb{R}] \), where \( A = [a_{ij}] \) and \( B = [b_{ij}] \). The sum \( A + B \) of \( A \) and \( B \) is defined as that \( m \times n \) matrix \( [c_{ij}] \), where \( c_{ij} = a_{ij} + b_{ij} \) for all integers \( i \) and \( j \) with \( 1 \leq i \leq m \) and \( 1 \leq j \leq n \). For \( \alpha \in \mathbb{R} \), the scalar multiple \( \alpha A \) of \( A \) by \( \alpha \) is defined as \( \alpha A = [d_{ij}] \), where \( d_{ij} = \alpha a_{ij} \) for all integers \( i \) and \( j \) with \( 1 \leq i \leq m \) and \( 1 \leq j \leq n \). For example, if
\[
A = \begin{bmatrix} 2 & -1 & -3 \\ 0 & 4 & 0 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 3 & -9 & 2 \\ -2 & 5 & 0 \end{bmatrix},
\]
then
\[
A + B = \begin{bmatrix} 5 & -10 & -1 \\ -2 & 9 & 0 \end{bmatrix} \quad \text{and} \quad (-2)A = \begin{bmatrix} -4 & 2 & 6 \\ 0 & -8 & 0 \end{bmatrix}.
\]
Under this addition and scalar multiplication, \( M_{mn}[\mathbb{R}] \) is a vector space. As an illustration, we verify that properties 1 and 3–5 of a vector space are satisfied in \( M_{22}[\mathbb{R}] \). Let \( \alpha \in \mathbb{R} \) and let
\[
A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix}.
\]
Then
\[
A + B = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} + \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \begin{bmatrix} a_{11} + b_{11} & a_{12} + b_{12} \\ a_{21} + b_{21} & a_{22} + b_{22} \end{bmatrix}.
\]
This verifies property 1 of a vector space. We see here that verifying property 1 depends only on the definition of addition of matrices and the fact that real numbers are commutative under addition.

Let \( Z = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \), often called the \( 2 \times 2 \) zero matrix. Then
\[
A + Z = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} a_{11} + 0 & a_{12} + 0 \\ a_{21} + 0 & a_{22} + 0 \end{bmatrix} = A
\]
\[
= \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = A
\]
and so $Z$ is a zero element of $M_2[\mathbb{R}]$, thereby verifying property 3.

Next, let $-A = \begin{bmatrix} -a_{11} & -a_{12} \\ -a_{21} & -a_{22} \end{bmatrix}$. Consequently,

$$A + (-A) = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} + \begin{bmatrix} -a_{11} & -a_{12} \\ -a_{21} & -a_{22} \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} = Z,$$

and so $-A$ is a negative of $A$. Therefore, property 4 is satisfied. We note also that if $A$ is multiplied by the scalar $-1$, then we obtain

$$(-1)A = (-1) \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} -a_{11} & -a_{12} \\ -a_{21} & -a_{22} \end{bmatrix} = -A.$$

Finally,

$$\alpha(A + B) = \alpha \begin{bmatrix} a_{11} + b_{11} & a_{12} + b_{12} \\ a_{21} + b_{21} & a_{22} + b_{22} \end{bmatrix} = \begin{bmatrix} \alpha(a_{11} + b_{11}) & \alpha(a_{12} + b_{12}) \\ \alpha(a_{21} + b_{21}) & \alpha(a_{22} + b_{22}) \end{bmatrix}$$

$$= \begin{bmatrix} \alpha a_{11} + \alpha b_{11} & \alpha a_{12} + \alpha b_{12} \\ \alpha a_{21} + \alpha b_{21} & \alpha a_{22} + \alpha b_{22} \end{bmatrix} = \alpha \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} + \alpha \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \end{bmatrix} = \alpha A + \alpha B.$$

Under the right set of circumstances, matrices can also be multiplied — although this, of course, is not a requirement for a vector space.

Let $A = [a_{ij}]$ be an $m \times n$ matrix and $B = [b_{ij}]$ be an $n \times r$ matrix, that is, let $A$ and $B$ be two matrices, where the number of columns in $A$ equals the number of rows in $B$. In this case, we define the product $AB$ of $A$ and $B$ as that $m \times r$ matrix $[c_{ij}]$, where

$$c_{ij} = a_{i1}b_{1j} + a_{i2}b_{2j} + \cdots + a_{in}b_{nj} = \sum_{k=1}^{n} a_{ik}b_{kj} \quad (17.1)$$

for all integers $i$ and $j$ with $1 \leq i \leq m$ and $1 \leq j \leq r$. Hence, the $(i, j)$-entry of $AB$ is obtained from the $i$th row of $A$ and the $j$th column of $B$, namely,

$$[a_{i1} \ a_{i2} \ \ldots \ a_{in}] \quad \text{and} \quad \begin{bmatrix} b_{1j} \\ b_{2j} \\ \vdots \\ b_{nj} \end{bmatrix},$$

by multiplying corresponding terms of this row and column and then adding all $n$ products. The expression (17.1) is referred to as the **inner product** of the $i$th row of $A$ and the $j$th column of $B$. For example, let

$$A = \begin{bmatrix} 1 & -3 & 5 & 0 \\ -1 & 0 & 6 & 2 \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} 1 & -6 & 5 \\ 2 & 0 & 1 \\ 3 & 3 & 2 \\ -6 & 9 & 0 \end{bmatrix}.$$
17.4 Some Properties of Vector Spaces

Since $A$ is a $2 \times 4$ matrix and $B$ is a $4 \times 3$ matrix, the product $AB$ is defined and, in fact, $AB = [c_{ij}]$ is the $2 \times 3$ matrix, where the six inner products are

- $c_{11} = 1 \cdot 1 + (-3) \cdot 2 + 5 \cdot 3 + 0 \cdot (-6) = 10$
- $c_{12} = 1 \cdot (-6) + (-3) \cdot 0 + 5 \cdot 3 + 0 \cdot 9 = 9$
- $c_{13} = 1 \cdot 5 + (-3) \cdot 1 + 5 \cdot 2 + 0 \cdot 0 = 12$
- $c_{21} = (-1) \cdot 1 + 0 \cdot 2 + 6 \cdot 3 + 2 \cdot (-6) = 5$
- $c_{22} = (-1) \cdot (-6) + 0 \cdot 0 + 6 \cdot 3 + 2 \cdot 9 = 42$
- $c_{23} = (-1) \cdot 5 + 0 \cdot 1 + 6 \cdot 2 + 2 \cdot 0 = 7$.

Hence,

$$AB = \begin{bmatrix} 10 & 9 & 12 \\ 5 & 42 & 7 \end{bmatrix}.$$  

On the other hand, since the matrix $B$ is a $4 \times 3$ matrix and $A$ is a $2 \times 4$ matrix, the product $BA$ is not defined. Certainly, however, if $A$ and $B$ are any two square matrices of the same size, then $AB$ and $BA$ are both defined though they need not be equal. For example, if

$A = \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix}$ and $B = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix},$

then

$$AB = \begin{bmatrix} 2 & 1 \\ 2 & 1 \end{bmatrix},$$ while $$BA = \begin{bmatrix} 1 & 2 \\ 1 & 2 \end{bmatrix}. $$

17.4 SOME PROPERTIES OF VECTOR SPACES

Although we have now seen several different vector spaces, there are a number of properties that these and all vector spaces have in common (in addition to the eight defining properties). Since vector spaces are defined by eight properties, one might expect, and rightfully so, that any other properties they have in common are consequences of these eight properties.

According to property 3, every vector space contains at least one zero vector and by property 4, every vector has at least one negative. We show that “at least one” can be replaced by “exactly one” in both instances. Actually, these are consequences of the fact that every vector space is a group under addition (Chapter 15). We verify these nevertheless.

**Theorem 17.1** Every vector space has a unique zero vector.

**Proof** Let $V$ be a vector space and assume that $z$ and $z'$ are both zero vectors in $V$. Since $z$ is a zero vector, $z' + z = z'$. Moreover, since $z'$ is a zero vector, $z + z' = z$. Therefore, $z = z + z' = z' + z = z'$.
10 Chapter 17 Proofs in Linear Algebra

As a consequence of Theorem 17.1, we now know that a vector space $V$ possesses only one zero vector $z$ that satisfies property 3 of a vector space. Hence, we can now refer to $z$ as the zero vector of $V$.

**Theorem 17.2** Let $V$ be a vector space. Then every vector in $V$ has a unique negative.

**Proof** Let $v \in V$ and assume that $v_1$ and $v_2$ are both negatives of $v$. Thus, $v + v_1 = z$ and $v + v_2 = z$. Hence,

$$v_1 = v_1 + z = v_1 + (v + v_2) = (v_1 + v) + v_2 = z + v_2 = v_2.$$}

It is also possible to give a proof of this theorem using the cancellation law in Exercise 17.6(a). In this case, if $v_1$ and $v_2$ are both negatives of a vector $v$ in the vector space $V$, then $v + v_1 = z$ and $v + v_2 = z$, and so $v + v_1 = v + v_2$. Applying the cancellation law gives us $v_1 = v_2$.

As a consequence of Theorem 17.2, we can now refer to $-v$ as the negative of $v$. Of course, the zero vector $z$ has the property that $z + z = z$. However, no other vector has this property.

**Theorem 17.3** Let $V$ be a vector space. If $v$ is a vector such that $v + v = v$, then $v = z$.

**Proof** Since $v + (-v) = z$, it follows that

$$z = v + (-v) = (v + v) + (-v) = v + (v + (-v)) = v + z = v.$$}

A proof like that given for Theorem 17.3 can be obtained by adding $-v$ to the equal vectors $v + v$ and $v$ and proceeding as we did in the discussion following the proof of Theorem 17.2. Also, see Exercise 17.6(b).

We now describe two other properties concerning the zero vector that are consequences of Theorem 17.3.

**Corollary 17.4** Let $V$ be a vector space. Then

(i) $0v = z$ for every vector $v$ in $V$ and

(ii) $\alpha z = z$ for every scalar $\alpha \in \mathbb{R}$.

**Proof** First, we prove (i). Observe that

$$0v = (0 + 0)v = 0v + 0v.$$}

By Theorem 17.3, $0v = z$.

Next we verify (ii). Observe that

$$\alpha z = \alpha (z + z) = \alpha z + \alpha z.$$}

Again, by Theorem 17.3, $\alpha z = z$.

Hence, by Corollary 17.4, $0v = z$ for every vector $v$ in a vector space and $\alpha z = z$ for every scalar $\alpha$. That is, if either $\alpha = 0$ or $v = z$, then $\alpha v = z$. We now show that the converse of this statement is true as well.
Theorem 17.5 Let $V$ be a vector space. If $\alpha v = z$, then either $\alpha = 0$ or $v = z$.

Proof Suppose that $\alpha v = z$ and that $\alpha \neq 0$. It then follows that

$$v = 1v = \left(\frac{1}{\alpha}\right)v = \left(\frac{1}{\alpha}\right)(\alpha v) = \left(\frac{1}{\alpha}\right)z = z,$$

a contradiction. ■

Another useful property is that the scalar multiple of a vector by $-1$ is the negative of that vector. Actually, we have observed this earlier with two particular vector spaces but this is true in general.

Theorem to Prove If $v$ is a vector in a vector space, then $(-1)v = -v$.

Proof Strategy Since $v$ has a unique negative, to show that $(-1)v = -v$, we need only verify that the sum of $v$ and $(-1)v$ is $z$. ♦

Theorem 17.6 If $v$ is a vector in a vector space, then $(-1)v = -v$.

Proof Observe that

$$v + (-1)v = 1v + (-1)v = (1 + (-1))v = 0v = z.$$

Hence, $(-1)v = -v$. ■

17.5 SUBSPACES

Earlier we saw that $F_R = \{ f : f : R \rightarrow R \}$ is a vector space (under function addition and scalar multiplication). Since the set $R[x]$ of all polynomial functions over $R$ is a subset of $F_R$ and the addition and scalar multiplication defined in $R[x]$ are exactly the same as those defined in $F_R$, it was considerably easier to show that $R[x]$ is a vector space. This idea can be made more general.

For a vector space $V$, a subset $W$ of $V$ is called a subspace of $V$ if $W$ is vector space under the same addition and scalar multiplication defined on $V$. Hence, if $W$ is a subspace of a known vector space $V$, then $W$ itself is a vector space. Since every subspace contains a zero vector, $W$ must be nonempty.

As we study vector spaces further, we will see that certain subspaces appear regularly and consequently it is beneficial to have an understanding of subspaces. Furthermore, some sets having an addition and scalar multiplication defined on them are subsets of known vector spaces and can be shown to be vector spaces more easily by verifying that they are subspaces.

If $W$ is a subset of a vector space $V$, what is required to show that $W$ is a subspace of $V$? Of course, $W$ must satisfy the eight properties required of all vector spaces. In addition, if $u, v \in W$, then $u + v$ must belong to $W$. This property is expressed by saying
that \( W \) is **closed under addition**. Also, if \( \alpha \) is a scalar (a real number) and \( v \in W \), then \( \alpha v \) must belong to \( W \). We express this property by saying that \( W \) is **closed under scalar multiplication**.

Property 1 (the commutative property) requires that \( u + v = v + u \) for every two vectors \( u \) and \( v \) in \( W \). However, \( V \) is a vector space and satisfies property 1. Thus, \( u + v = v + u \) in \( W \) and so \( W \) satisfies property 1. By the same reasoning, property 2 and properties 5–8 are satisfied by \( W \). These properties of \( W \) are said to be **inherited** from \( V \). Hence, for a nonempty subset \( W \) of a vector space \( V \) to be a subspace of \( V \), it is necessary that \( W \) be closed under addition and scalar multiplication. Perhaps surprisingly, these requirements are sufficient as well for a nonempty subset \( W \) of \( V \) to be a subspace of \( V \).

**Theorem 17.7** (**The Subspace Test**) A nonempty subset \( W \) of a vector space \( V \) is a subspace of \( V \) if and only if \( W \) is closed under addition and scalar multiplication.

**Proof** First, let \( W \) be a subspace of \( V \). Certainly, \( W \) is closed under addition and scalar multiplication. For the converse, let \( W \) be a nonempty subset of \( V \) that is closed under addition and scalar multiplication. As we noted earlier, \( W \) inherits properties 1, 2 and 5–8 of a vector space from \( V \). Since \( W \) is nonempty and is closed under addition and scalar multiplication, only properties 3 and 4 remain to be verified. Since \( W \neq \emptyset \), there is some vector \( v \) in \( W \). Since \( W \) is closed under scalar multiplication, it follows by Corollary 17.4(i) that \( 0v = 0 \in W \). Hence, \( W \) contains a zero vector (namely the zero vector of \( V \)) and property 3 is satisfied. Now let \( w \) be any vector of \( W \). Again, \((-1)w \in W \). However, by Theorem 17.6, \((-1)w = -w \in W \), and so \( w \) has a negative in \( W \) (namely the negative of \( w \) in \( V \)). Thus, property 4 is satisfied in \( W \) as well.

The proof of Theorem 17.7 brings out two important facts. Namely, if \( W \) is a subspace of a vector space \( V \), then \( W \) contains a zero vector (namely, the zero vector of \( V \)) and for every vector \( w \in W \), its negative \(-w \) belongs to \( W \) as well.

Every vector space \( V \) (containing at least two elements) always contains two subspaces, namely \( V \) itself and the subspace consisting only of the zero vector of \( V \). We now present several examples to illustrate how the Subspace Test (Theorem 17.7) can be applied to show that certain subsets of a vector space are (or are not) subspaces of that vector space. The first two examples concern the vector space \( \mathbb{R}^3 \).

**Result 17.8** The set

\[
W = \{(a, b, 2a - b) : a, b \in \mathbb{R}\}
\]

is a subspace of \( \mathbb{R}^3 \).

First, observe that \( W \) is defined as the collection of vectors of \( \mathbb{R}^3 \) whose 3rd coordinate is twice the first coordinate minus the second coordinate. So, for example, \( W \) contains \((3, 2, 4)\), taking \( a = 3 \) and \( b = 2 \), as well as \((0, 0, 0)\), taking \( a = b = 0 \). Of course, if \( W \) is to be a subspace of \( \mathbb{R}^3 \), then it is essential that \( W \) contains the zero vector of \( \mathbb{R}^3 \).

**Proof of Result 17.8** Since \( W \) contains the zero vector of \( \mathbb{R}^3 \), it follows that \( W \neq \emptyset \). To show that \( W \) is a subspace of \( V \), we need only show that \( W \) is closed under addition (that is, if \( u, v \in W \), then \( u + v \in W \)) and that \( W \) is closed under scalar multiplication (that is, if \( u \in W \)
17.5 Subspaces

and $\alpha \in \mathbf{R}$, then $\alpha \mathbf{u} \in W$). Let $\mathbf{u}, \mathbf{v} \in W$ and $\alpha \in \mathbf{R}$. Then $\mathbf{u} = (a, b, 2a - b)$ and $\mathbf{v} = (c, d, 2c - d)$, where $a, b, c, d \in \mathbf{R}$. Therefore,

$$\mathbf{u} + \mathbf{v} = (a + c, b + d, 2(a + c) - (b + d)) \in W \quad \text{and} \quad \alpha \mathbf{u} = (\alpha a, \alpha b, 2(\alpha a) - (\alpha b)) \in W.$$  

By the Subspace Test, $W$ is a subspace of $\mathbf{R}^3$.

Example 17.9 Determine whether

$$W = \{(a, b, a^2 + b) : a, b \in \mathbf{R}\}$$

is a subspace of $\mathbf{R}^3$.

**Solution** Taking $a = b = 1$, we see that $\mathbf{u} = (1, 1, 2) \in W$. Then $2\mathbf{u} = (2, 2, 4)$. Since $4 \neq 2^2 + 2$, it follows that $2\mathbf{u} \notin W$. Since $W$ is not closed under scalar multiplication, $W$ is not a subspace of $\mathbf{R}^3$. (The subset $W$ of $\mathbf{R}^3$ is not closed under addition either since $\mathbf{u} + \mathbf{u} \notin W$.)

We next consider the vector space $\mathcal{F}_\mathbf{R}$. We have already mentioned that $\mathbf{R}[x]$ is a subspace of $\mathcal{F}_\mathbf{R}$. Also, the set $\mathcal{C}_\mathbf{R} = \{f \in \mathcal{F}_\mathbf{R} : f \text{ is continuous}\}$ is a subspace of $\mathcal{F}_\mathbf{R}$. Indeed, $\mathbf{R}[x]$ is a subspace of $\mathcal{C}_\mathbf{R}$ as well.

**Result 17.10** Let $\mathcal{F}_0 = \{f \in \mathcal{F}_\mathbf{R} : f(1) = 0\}$. Then $\mathcal{F}_0$ is a subspace of $\mathcal{F}_\mathbf{R}$.

Hence, the function $f_1 : \mathbf{R} \to \mathbf{R}$ defined by $f_1(x) = x - 1$ belongs to $\mathcal{F}_0$, as does the zero function $f_0 : \mathbf{R} \to \mathbf{R}$ defined by $f_0(x) = 0$ for all $x \in \mathbf{R}$.

**Proof of Result 17.10** Since $\mathcal{F}_0$ contains the zero function, $\mathcal{F}_0 \neq \emptyset$. Let $f, g \in \mathcal{F}_0$ and $\alpha \in \mathbf{R}$. Then

$$(f + g)(1) = f(1) + g(1) = 0 + 0 = 0 \quad \text{and} \quad (\alpha f)(1) = \alpha f(1) = \alpha \cdot 0 = 0.$$  

Thus, $f + g \in \mathcal{F}_0$ and $\alpha f \in \mathcal{F}_0$. By the Subspace Test, $\mathcal{F}_0$ is a subspace of $\mathcal{F}_\mathbf{R}$.

**Example 17.11** Determine whether

$$\mathcal{F}_1 = \{f \in \mathcal{F}_\mathbf{R} : f(0) = 1\}$$

is a subspace of $\mathcal{F}_\mathbf{R}$.

**Solution** Observe that the functions $g, h \in \mathcal{F}_\mathbf{R}$ defined by $g(x) = x + 1$ and $h(x) = x^2 + 1$ belong to $\mathcal{F}_1$. However, $(g + h)(x) = g(x) + h(x) = x^2 + x + 2$ and $(g + h)(0) = 2$, so $g + h \notin \mathcal{F}_1$. Therefore, $\mathcal{F}_1$ is not closed under addition and so $\mathcal{F}_1$ is not a subspace of $\mathcal{F}_\mathbf{R}$.

The next example concerns the vector space $M_2(\mathbf{R})$ of $2 \times 2$ matrices with real entries.

**Result 17.12** The set

$$W = \left\{ \begin{bmatrix} a & 0 \\ b & c \end{bmatrix} : a, b, c \in \mathbf{R} \right\}$$

is a subspace of $M_2(\mathbf{R})$. 
14 Chapter 17 Proofs in Linear Algebra

Hence, \( W \) consists of all those \( 2 \times 2 \) matrices whose \((1, 2)\)-entry is 0. Thus, the zero matrix, all of whose entries are 0, belongs to \( W \).

**Proof of Result 17.12**

Since \( W \) contains the zero matrix, \( W \neq \emptyset \). Let \( A, B \in W \) and \( \alpha \in \mathbb{R} \). So,

\[
A = \begin{bmatrix} a & 0 \\ b & c \end{bmatrix} \quad \text{and} \quad B = \begin{bmatrix} d & 0 \\ e & f \end{bmatrix},
\]

where \( a, b, c, d, e, f \in \mathbb{R} \). Then

\[
A + B = \begin{bmatrix} a + d & 0 \\ b + e & c + f \end{bmatrix} \quad \text{and} \quad \alpha A = \begin{bmatrix} \alpha a & 0 \\ \alpha b & \alpha c \end{bmatrix}.
\]

Therefore, \( A + B \) and \( \alpha A \) belong to \( W \) and by the Subspace Test, \( W \) is a subspace of \( M_2(\mathbb{R}) \).

17.6 SPANS OF VECTORS

In Result 17.12 we showed that the set

\[
W = \left\{ \begin{bmatrix} a \\ b \\ c \end{bmatrix} : a, b, c \in \mathbb{R} \right\}
\]

is a subspace of \( M_2(\mathbb{R}) \). Thus, if \( A \in W \), then \( A = \begin{bmatrix} a & 0 \\ b & c \end{bmatrix} \) for some \( a, b, c \in \mathbb{R} \). Observe, also, that

\[
A = \begin{bmatrix} a & 0 \\ b & c \end{bmatrix} = \begin{bmatrix} a & 0 \\ 0 & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ b & 0 \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & c \end{bmatrix} = a \begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix} + b \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} + c \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}.
\]

In other words, \( A \) (and, consequently, every matrix in \( W \)) is a linear combination of

\[
\begin{bmatrix} 1 & 0 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 0 \\ 1 & 0 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}.
\]

Therefore, \( W \) is the set of all linear combinations of these three matrices. This observation illustrates a more general situation.

Recall that if \( V \) is a vector space, \( v_1, v_2, \ldots, v_n \in V \) and \( \alpha_1, \alpha_2, \ldots, \alpha_n \in \mathbb{R} \), then every vector of the form \( \alpha_1 v_1 + \alpha_2 v_2 + \cdots + \alpha_n v_n \) is a **linear combination** of the vectors \( v_1, v_2, \ldots, v_n \). Thus, by taking \( \alpha_1 = \alpha_2 = \cdots = \alpha_n = 0 \), we see that the zero vector is a linear combination of \( v_1, v_2, \ldots, v_n \). Also, by taking \( \alpha_i = 1 \) for a fixed integer \( i \) \((1 \leq i \leq n) \) and all other scalars 0, we see that each vector \( v_i \) is a linear combination of \( v_1, v_2, \ldots, v_n \). We have noted that every linear combination of vectors in \( V \) is a vector in \( V \) and, of course, the set of all such linear combinations is a subset of \( V \). In fact, more can be said of this subset.

**Theorem 17.13** Let \( V \) be a vector space containing the vectors \( v_1, v_2, \ldots, v_n \). Then the set \( W \) of all linear combinations of \( v_1, v_2, \ldots, v_n \) is a subspace of \( V \).

**Proof** Since \( W \) contains the zero vector of \( V \), it follows that \( W \neq \emptyset \). Let \( u, w \in W \) and let \( \alpha \in \mathbb{R} \). Then \( u = \alpha_1 v_1 + \alpha_2 v_2 + \cdots + \alpha_n v_n \) and \( w = \beta_1 v_1 + \beta_2 v_2 + \cdots + \beta_n v_n \), where
17.6 Spans of Vectors

\[ \alpha_i, \beta_i \in \mathbb{R} \text{ for } 1 \leq i \leq n. \text{ Then} \]
\[ \mathbf{u} + \mathbf{w} = (\alpha_1 + \beta_1)\mathbf{v}_1 + (\alpha_2 + \beta_2)\mathbf{v}_2 + \cdots + (\alpha_n + \beta_n)\mathbf{v}_n \text{ and} \]
\[ \alpha \mathbf{u} = (\alpha \alpha_1)\mathbf{v}_1 + (\alpha \alpha_2)\mathbf{v}_2 + \cdots + (\alpha \alpha_n)\mathbf{v}_n. \]

So, both \( \mathbf{u} + \mathbf{w} \) and \( \alpha \mathbf{u} \) are linear combinations of \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \) and, hence, belong to \( W \).

Thus, by the Subspace Test, \( W \) is a subspace of \( V \). \( \square \)

For vectors \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \) in a vector space \( V \), the subspace \( W \) of \( V \) consisting of all linear combinations of \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \) is called the \textbf{span} of \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \) and is denoted by \( \langle \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \rangle \). Also, \( W \) is referred to as the subspace of \( V \) \textbf{spanned} by \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \).

By Result 17.12,
\[ W = \left\{ \begin{bmatrix} a & 0 \\ b & c \end{bmatrix} : a, b, c \in \mathbb{R} \right\} = \left\langle \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix}, \begin{bmatrix} 0 \\ 0 \end{bmatrix} \right\rangle. \]

We saw in Result 17.8 that \( W = \{(a, b, 2a - b) : a, b \in \mathbb{R}\} \) is a subspace of \( \mathbb{R}^3 \). Since \( (a, b, 2a - b) = a(1, 0, 2) + b(0, 1, -1) \), it follows that \( W \) is spanned by the vectors \((1, 0, 2)\) and \((0, 1, -1)\), that is, \( W = \{(1, 0, 2), (0, 1, -1)\} \).

We consider another illustration of spans of vectors.

\textbf{Result 17.14} Let \( f_1, f_2, f_3, g_2, g_3 \) be five functions in \( \mathbb{R}[x] \) defined by \( f_1(x) = 1 \), \( f_2(x) = 1 + x^2 \), \( f_3(x) = 1 + x^2 + x^4 \), \( g_2(x) = x^2 \) and \( g_3(x) = x^4 \) for all \( x \in \mathbb{R} \), and let \( W = \langle f_1, f_2, f_3 \rangle \) and \( W' = \langle f_1, g_2, g_3 \rangle \). Then \( W = W' \).

\textbf{Proof Strategy} Since \( W \) and \( W' \) are sets of vectors (polynomial functions) and our goal is to show that \( W = W' \), we proceed in the standard manner by showing that each of \( W \) and \( W' \) is a subset of the other.

\textbf{Proof of Result 17.14} First, we show that \( W \subseteq W' \). Let \( f \in W \). Then \( f = af_1 + bf_2 + cf_3 \) for some \( a, b, c \in \mathbb{R} \). Hence, for each \( x \in \mathbb{R} \),
\[ f(x) = a \cdot 1 + b \cdot (1 + x^2) + c \cdot (1 + x^2 + x^4) \]
\[ = (a + b + c) \cdot 1 + (b + c) \cdot x^2 + c \cdot x^4. \]

Thus, \( f \) is also a linear combination of \( f_1, g_2 \) and \( g_3 \). Consequently, \( W \subseteq W' \). It remains to show that \( W' \subseteq W \). Let \( g \in W' \). Then
\[ g = af_1 + bg_2 + cg_3 \text{ for some } a, b, c \in \mathbb{R}. \]

So, for each \( x \in \mathbb{R} \),
\[ g(x) = a \cdot 1 + b \cdot x^2 + c \cdot x^4 = (a - b) \cdot 1 + b \cdot (1 + x^2) + c \cdot x^4 \]
\[ = (a - b) \cdot 1 + (b - c) \cdot (1 + x^2) + c \cdot (1 + x^2 + x^4). \]

Hence, \( g \) is also a linear combination of \( f_1, f_2, f_3 \) as well and so \( W' \subseteq W \). \( \square \)

From what we have seen, if \( V \) is a vector space containing the vectors \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \), then \( W = \langle \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \rangle \) is a subspace of \( V \) (that contains \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \)). Quite possibly other subspaces of \( V \) contain \( \mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \) as well. Of course, \( V \) itself is a subspace
let $v_1, v_2, \ldots, v_n$. In a certain sense though, $W$ is the smallest subspace of $V$ containing $v_1, v_2, \ldots, v_n$.

**Theorem 17.15** Let $V$ be a vector space containing the vectors $v_1, v_2, \ldots, v_n$ and let $W = \langle v_1, v_2, \ldots, v_n \rangle$. If $W'$ is a subspace of $V$ containing $v_1, v_2, \ldots, v_n$, then $W$ is a subspace of $W'$.

**Proof** Since $W$ and $W'$ are subspaces of $V$, we need only show that $W \subseteq W'$. Let $v \in W$. Thus, $v = a_1v_1 + a_2v_2 + \cdots + a_nv_n$, where $a_i \in \mathbb{R}$ for $1 \leq i \leq n$. Since $v_i \in W'$ for $1 \leq i \leq n$ and $W'$ is a subspace of $V$, it follows that $v \in W'$. Hence, $W \subseteq W'$.

There is a consequence of Theorem 17.15 that is especially useful.

**Corollary 17.16** Let $V$ be a vector space spanned by the vectors $v_1, v_2, \ldots, v_n$. If $W$ is a subspace of $V$ containing $v_1, v_2, \ldots, v_n$, then $W = V$.

**Proof** Since $W$ is a subspace of $V$, certainly $W \subseteq V$. By Theorem 17.15, $V \subseteq W$. Thus, $W = V$.

To illustrate a number of the concepts and results introduced thus far, we consider an example concerning 3-space.

**Result 17.17**

(i) For the vectors $i = (1, 0, 0), j = (0, 1, 0)$ and $k = (0, 0, 1)$, $\mathbb{R}^3 = \langle i, j, k \rangle$.

(ii) If $w_1 = (1, 1, 0), w_2 = (0, 1, 1)$ and $w_3 = (1, 1, 1)$, then $\mathbb{R}^3 = \langle w_1, w_2, w_3 \rangle$.

(iii) Let $u_1 = (1, 1, 1), u_2 = (1, 1, 0)$ and $u_3 = (0, 1, 0)$. Then $\langle u_1, u_2, u_3 \rangle = \langle u_1, u_2 \rangle$.

**Proof** Let $W_1 = \langle i, j, k \rangle$. Since $W_1$ is a subspace of $\mathbb{R}^3$, it follows that $W_1 \subseteq \mathbb{R}^3$. We now show that $\mathbb{R}^3 \subseteq W_1$. Let $v \in \mathbb{R}^3$. So, $v = (a, b, c)$, where $a, b, c \in \mathbb{R}$. Then $v = (a, 0, 0) + (0, b, 0) + (0, 0, c) = ai + bj + ck$. Hence, $v$ is a linear combination of $i, j$ and $k$ and so $v \in W_1$. Hence, $\mathbb{R}^3 \subseteq W_1$. This implies that $\mathbb{R}^3 = \langle i, j, k \rangle$ and (i) is verified.

Next, we verify (ii). Let $W_2 = \langle w_1, w_2, w_3 \rangle$. To verify that $\mathbb{R}^3 = W_2$, it suffices to show by Corollary 17.16 and part (i) of this result that each of the vectors $i, j$ and $k$ belongs to $W_2$. To show that $i, j$ and $k$ belong to $W_2$, we are then required to show that each of $i, j$ and $k$ is a linear combination of $w_1, w_2$ and $w_3$. Since $i = (1, 1, 1) + (-1)(0, 1, 1)$, it follows that $i = 0 \cdot w_1 + (-1)w_2 + 1 \cdot w_3$. Now $j = (0, 1, 0) = (1, 1, 1) + (-1)(0, 1, 1)$, so $j = 1 \cdot w_1 + 1 \cdot w_2 + (-1)w_3$. Finally, $k = (0, 0, 1) = (1, 1, 1) + (-1)(1, 1, 0)$ and so $k = (-1)w_1 + 0 \cdot w_2 + 1 \cdot w_3$. Hence, $\mathbb{R}^3 = W_2$ and (ii) is established.

Finally, we verify (iii). Let $W = \langle u_1, u_2 \rangle$ and $W' = \langle u_1, u_2, u_3 \rangle$. Since $W'$ contains the vectors $u_1$ and $u_2$, it follows by Theorem 17.15 that $W \subseteq W'$.

By Corollary 17.16, to prove that $W' \subseteq W$, we need only show that each of the vectors $u_1, u_2$ and $u_3$ in $W'$ belongs to $W$, that is, each of these three vectors is a linear combination of $u_1$ and $u_2$. This is obvious for $u_1$ and $u_2$ as $u_1 = 1 \cdot u_1 + 0 \cdot u_2$ and $u_2 = 0 \cdot u_1 + 1 \cdot u_2$. Thus, it remains only to show that $u_3$ is a linear combination of $u_1$ and $u_2$. However, $u_3 = (0, 0, 1) = (1, 1, 1) + (-1)(1, 1, 0) = 1 \cdot u_1 + (-1)u_2$, completing the proof.
17.7 Linear Dependence and Independence

For the vectors \( \mathbf{u}_1 = (1, 1, 0) \) and \( \mathbf{u}_2 = (0, 1, 1) \) in \( \mathbb{R}^3 \), the vector \( \mathbf{u}_3 = (-1, 1, 2) \) is a linear combination of \( \mathbf{u}_1 \) and \( \mathbf{u}_2 \) since

\[
\mathbf{u}_3 = (-1, 1, 2) = (-1) \cdot \mathbf{u}_1 + 2 \cdot \mathbf{u}_2 = (-1) \cdot (1, 1, 0) + 2 \cdot (0, 1, 1).
\]

Therefore, in a certain sense, the vector \( \mathbf{u}_3 \) depends on \( \mathbf{u}_1 \) and \( \mathbf{u}_2 \) in a linear manner.

This linear dependence can be restated as

\[
(-1) \cdot \mathbf{u}_1 + 2 \cdot \mathbf{u}_2 + (-1) \cdot \mathbf{u}_3 = (0, 0, 0).
\]

This kind of dependence plays an important role in linear algebra.

Let \( S = \{ \mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m \} \) be a nonempty set of vectors in a vector space \( V \). The set \( S \) is called linearly dependent if there exist scalars \( c_1, c_2, \ldots, c_m \), not all 0, such that \( c_1 \mathbf{u}_1 + c_2 \mathbf{u}_2 + \cdots + c_m \mathbf{u}_m = \mathbf{z} \). If \( S \) is not linearly dependent, then \( S \) is said to be linearly independent. For \( S = \{ \mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m \} \), we also say that the vectors \( \mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m \) are linearly dependent or linearly independent according to whether the set \( S \) is linearly dependent or linearly independent, respectively. Consequently, the vectors \( \mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_m \) are linearly independent if whenever \( c_1 \mathbf{u}_1 + c_2 \mathbf{u}_2 + \cdots + c_m \mathbf{u}_m = \mathbf{z} \), then \( c_i = 0 \) for each \( i \) \((1 \leq i \leq m)\).

We now consider some examples.

**Example 17.18** Determine whether \( S = \{(1, 1, 1), (1, 1, 0), (0, 1, 1)\} \) is a linearly independent set of vectors in \( \mathbb{R}^3 \).

**Solution** Let \( a, b \) and \( c \) be scalars such that

\[
a \cdot (1, 1, 1) + b \cdot (1, 1, 0) + c \cdot (0, 1, 1) = (0, 0, 0).
\]

By scalar multiplication and vector addition, we have \( (a + b, a + b + c, a + c) = (0, 0, 0) \), arriving at the following system of equations:

\[
\begin{align*}
    a + b &= 0 \\
    a + b + c &= 0 \\
    a + c &= 0.
\end{align*}
\]

Subtracting the first equation from the second, we obtain \( c = 0 \). Substituting \( c = 0 \) into the third equation, we obtain \( a = 0 \). Substituting \( a = 0 \) and \( c = 0 \) into the second equation, we obtain \( b = 0 \). Hence, \( a = b = c = 0 \) and \( S \) is linearly independent. ♦

**Example 17.19** Determine whether

\[
S = \left\{ \begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 1 & 2 \end{bmatrix}, \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \right\}
\]

is a linearly independent set of vectors in \( M_2(\mathbb{R}) \).

**Solution** Again, let \( a, b \) and \( c \) be scalars such that

\[
a \begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix} + b \begin{bmatrix} 0 & 1 \\ 1 & 2 \end{bmatrix} + c \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}.
\]
By scalar multiplication and matrix addition, we have

\[
\begin{bmatrix}
2a + c & a + b + c \\
a + b + c & 2b + c
\end{bmatrix} = \begin{bmatrix}
0 & 0 \\
0 & 0
\end{bmatrix}.
\]

This results in the system of equations:

\[
\begin{align*}
2a + c &= 0 \\
a + b + c &= 0 \\
2b + c &= 0
\end{align*}
\]

where the second equation actually occurs twice. From the first and third equations, it follows that \( c = -2a \) and \( c = -2b \) and so \( a = b = -c/2 \). Substituting these values for \( a \) and \( b \) in the second equation gives \((-c/2) + (-c/2) + c = -c + c = 0\), that is, the second equation is satisfied for every value of \( c \). Hence, if we let \( c = -2 \), say, then \( a = b = 1 \) and

\[
\begin{bmatrix}
2 & 1 \\
0 & 1
\end{bmatrix} + \begin{bmatrix}
0 & 1 \\
1 & 2
\end{bmatrix} + (-2) \begin{bmatrix}
1 & 1 \\
1 & 1
\end{bmatrix} = \begin{bmatrix}
0 & 0 \\
0 & 0
\end{bmatrix}.
\]

Consequently, \( S \) is a linearly dependent set of vectors.

\[\blacklozenge\]

We now show that a familiar set of polynomial functions is linearly independent.

**Theorem to Prove**

For every nonnegative integer \( n \), the set \( S_n = \{1, x, x^2, \ldots, x^n\} \) is linearly independent in \( \mathbb{R}[x] \).

**Proof Strategy**

The elements of \( S_n \) are actually functions, say \( S_n = \{f_0, f_1, f_2, \ldots, f_n\} \), where \( f_i : \mathbb{R} \to \mathbb{R} \) is defined by \( f_i(x) = x^i \) for \( 0 \leq i \leq n \) and for all \( x \in \mathbb{R} \). To show that \( S_n \) is linearly independent, we are required to show that if \( c_0 \cdot 1 + c_1 x + c_2 x^2 + \cdots + c_n x^n = 0 \), where \( c_i \in \mathbb{R} \) for \( 0 \leq i \leq n \), then \( c_i = 0 \) for all \( i \). Of course, the question is how to do this. By choosing various values of \( x \), we could arrive at a system of equations to solve. For example, we could begin by letting \( x = 0 \), obtaining \( c_0 \cdot 1 + c_1 \cdot 0 + c_2 \cdot 0 + \cdots + c_n \cdot 0 = 0 \), and so \( c_0 = 0 \). Therefore, \( c_1 x + c_2 x^2 + \cdots + c_n x^n = 0 \). Letting \( x = 1 \) and \( x = 2 \), we have \( c_1 + c_2 + \cdots + c_n = 0 \) and \( 2c_1 + 2^2 c_2 + \cdots + 2^n c_n = 0 \). We could actually arrive at a system of \( n \) equations and \( n \) unknowns, but perhaps this is sounding complicated.

On the other hand, from the statement of the theorem, another approach is suggested. Quite often when we see a theorem stated as “for every nonnegative integer \( n \),” we think of applying induction. The main challenge to such a proof would be to show that if \( \{1, x, x^2, \ldots, x^k\} \) is linearly independent, where \( k \geq 0 \), then \( \{1, x, x^2, \ldots, x^{k+1}\} \) is linearly independent. Hence, we would be dealing with the equation \( c_0 \cdot 1 + c_1 x + c_2 x^2 + \cdots + c_{k+1} x^{k+1} = 0 \) for \( c_i \in \mathbb{R} \), \( 0 \leq i \leq k + 1 \), attempting to show that \( c_i = 0 \) for all \( i \) \((0 \leq i \leq k + 1)\). We already mentioned that showing \( c_0 = 0 \) is not difficult. In order to make use of the induction hypothesis, we need a linear combination of the polynomials \( 1, x, x^2, \ldots, x^k \). One idea for doing this is to take the derivative of \( c_0 \cdot 1 + c_1 x + c_2 x^2 + \cdots + c_{k+1} x^{k+1} \).

\[\blacklozenge\]
17.7 Linear Dependence and Independence

**Proof** We proceed by induction. For \( n = 0 \), we are required to show that \( S_0 = \{1\} \) is linearly independent in \( \mathbb{R}[x] \). Let \( c \) be a scalar such that \( c \cdot 1 = 0 \). Then surely \( c = 0 \) and so \( S_0 \) is linearly independent.

Assume that \( S_k = \{1, x, x^2, \ldots, x^k\} \) is linearly independent in \( \mathbb{R}[x] \), where \( k \) is a nonnegative integer. We show that \( S_{k+1} = \{1, x, x^2, \ldots, x^{k+1}\} \) is linearly independent in \( \mathbb{R}[x] \). Let \( c_0, c_1, \ldots, c_{k+1} \) be scalars such that

\[
c_0 \cdot 1 + c_1 x + c_2 x^2 + \cdots + c_{k+1} x^{k+1} = 0,
\]

for all \( x \in \mathbb{R} \). Letting \( x = 0 \) in (17.2), we see that \( c_0 = 0 \). Now taking the derivatives of both sides of (17.2), we see that

\[
c_1 \cdot 1 + 2c_2 x + 3c_3 x^2 + \cdots + (k+1)c_{k+1} x^k = 0
\]

for all \( x \in \mathbb{R} \). By the induction hypothesis, \( S_k \) is a linearly independent set of vectors in \( \mathbb{R}[x] \) and so \( c_1 = 2c_2 = 3c_3 = \cdots = (k+1)c_{k+1} = 0 \), which implies that \( c_1 = c_2 = c_3 = \cdots = c_{k+1} = 0 \). Since \( c_0 = 0 \) as well, it follows that \( S_{k+1} \) is linearly independent. \( \blacksquare \)

**Proof Analysis** Before proceeding further, it is important that we understand the proof we have just given. The proof began by showing that \( S_0 = \{1\} \) is linearly independent. What this means is that \( S_0 \) consists of the single constant polynomial function \( f \) defined by \( f(x) = 1 \) for all \( x \in \mathbb{R} \). Let \( c \) be a scalar (real number) such that \( c \cdot f = f_0 \), where \( f_0 \) is the zero polynomial function defined by \( f_0(x) = 0 \) for all \( x \in \mathbb{R} \). Thus, for each \( x \in \mathbb{R} \), \( (cf)(x) = f_0(x) = 0 \), that is,

\[
(cf)(x) = c \cdot f(x) = c \cdot 1 = 0 = f_0(x)
\]

and so \( c = 0 \).

We now consider a result for a general vector space.

**Result 17.21** If \( v_1, v_2 \) and \( v_3 \) are linearly independent vectors in a vector space \( V \), then \( v_1, v_1 + v_2 \) and \( v_1 + v_2 + v_3 \) are also linearly independent in \( V \).

**Proof** Let \( a, b \) and \( c \) be scalars such that

\[
a \cdot v_1 + b \cdot (v_1 + v_2) + c \cdot (v_1 + v_2 + v_3) = \mathbf{z}.
\]

From this, we have

\[
(a + b + c) \cdot v_1 + (b + c) \cdot v_2 + c \cdot v_3 = \mathbf{z}.
\]

Since \( v_1, v_2 \) and \( v_3 \) are linearly independent, \( a + b + c = b + c = c = 0 \), from which it follows that \( a = b = c = 0 \) and so \( v_1, v_1 + v_2 \) and \( v_1 + v_2 + v_3 \) are linearly independent. \( \blacksquare \)

Let \( S = \{v_1, v_2, \ldots, v_n\} \) be a set of \( n \) vectors, where \( n \in \mathbb{N} \), and let \( S' \) be a nonempty subset of \( S \). Then \( |S'| = m \) for some integer \( m \) with \( 1 \leq m \leq n \). Since the order in which the elements of \( S \) are listed is irrelevant, these elements can be rearranged and relabeled if necessary so that \( S' = \{v_1, v_2, \ldots, v_m\} \). This fact is quite useful at times.

**Theorem 17.22** Let \( S \) be a finite nonempty set of vectors in a vector space \( V \). If \( S \) is linearly independent in \( V \) and \( S' \) is a nonempty subset of \( S \), then \( S' \) is also linearly independent in \( V \).
Proof We may assume that $S' = \{v_1, v_2, \ldots, v_m\}$ and $S = \{v_1, v_2, \ldots, v_m, v_{m+1}, \ldots, v_n\}$, where then $1 \leq m \leq n$. If $m = n$, then $S' = S$ and surely $S'$ is linearly independent. Thus, we can assume that $m < n$. Let $c_1, c_2, \ldots, c_m$ be scalars such that $c_1v_1 + c_2v_2 + \cdots + c_mv_m = z$.

However, then, $c_1v_1 + c_2v_2 + \cdots + c_mv_m + 0v_{m+1} + 0v_{m+2} + \cdots + 0v_n = z$. (17.3)

Since $S$ is linearly independent, all scalars in (17.3) are 0. In particular, $c_1 = c_2 = \cdots = c_m = 0$, which implies that $S'$ is linearly independent.

We can restate Theorem 17.22 as follows: Let $V$ be a vector space and let $S$ and $S'$ be finite nonempty subsets of $V$ such that $S' \subseteq S$. If $S$ is linearly independent, then $S'$ is linearly independent. The contrapositive of this implication gives us: If $S'$ is linearly dependent, then $S$ is linearly dependent.

Although we have only discussed linear independence and linear dependence in connection with finite sets of vectors, these concepts exist for infinite sets of vectors as well. An infinite set of vectors in a vector space $V$ is **linearly independent** if every finite nonempty subset of $S$ is linearly independent. Equivalently, an infinite set $S$ of vectors in a vector space $V$ is **linearly dependent** if some finite nonempty subset of $S$ is linearly dependent. Every example we have seen of a (finite) set $S$ of linearly dependent vectors in some vector space $V$ gives rise to an infinite set $T$ of linearly dependent vectors, namely, any infinite subset $T$ of $V$ such that $S \subseteq T$ is linearly dependent. But what is an example of a vector space that contains infinitely many linearly independent vectors? We provide such an example now.

**Result 17.23** The set $T = \{1, x, x^2, \ldots\}$ is linearly independent in $\mathbb{R}[x]$.

**Proof** Let $S$ be a finite nonempty subset of $T$. Then there is a largest nonnegative integer $m$ such that $x^m \in S$. Therefore, $S \subseteq S_m = \{1, x, x^2, \ldots, x^m\}$. By Theorem 17.20, $S_m$ is linearly independent in $\mathbb{R}[x]$ and by Theorem 17.22, $S$ is linearly independent. Consequently, $T$ is linearly independent in $\mathbb{R}[x]$.

### 17.8 LINEAR TRANSFORMATIONS

We have seen that many properties of a vector space $V$, of subspaces of $V$, of the span of a set of vectors in $V$ and of linear independence and linear dependence of vectors in $V$ deal with a common concept: linear combinations of vectors. Perhaps this is not unexpected in an area of mathematics called linear algebra. There are occasions when two vectors spaces $V$ and $V'$ are so closely linked that with each vector $w \in V$, there is an associated vector $w' \in V'$ such that the vector associated with $\alpha u + \beta v$ in $V$ is $\alpha u' + \beta v'$ in $V'$. Such an association describes a function from $V$ to $V'$. In particular, a function $f : V \to V'$ is said to **preserve linear combinations** of vectors if $f(\alpha u + \beta v) = \alpha f(u) + \beta f(v)$ for all $u, v \in V$ and every two scalars $\alpha$ and $\beta$. If $f : V \to V'$ has the property that $f(u + v) = f(u) + f(v)$ for all $u, v \in V$, then $f$ is said to **preserve
addition. If \( f(\alpha u) = \alpha f(u) \) for all \( u \in V \) and every scalar \( \alpha \), then \( f \) is said to preserve scalar multiplication.

Let \( z' \) be the zero vector of \( V' \). If \( f : V \to V' \) preserves linear combinations and \( u, v \in V \), then

\[
f(u + v) = f(1 \cdot u + 1 \cdot v) = 1 \cdot f(u) + 1 \cdot f(v) = f(u) + f(v)
\]

and \( f(\alpha u) = f(\alpha u + 0v) = \alpha f(u) + 0f(v) = \alpha f(u) + z' = \alpha f(u) \). Hence, if \( f : V \to V' \) is a function that preserves linear combinations, then \( f \) preserves addition and scalar multiplication as well.

Conversely, suppose that \( f : V \to V' \) is a function that preserves both addition and scalar multiplication. Then for \( u, v \in V \) and scalars \( \alpha \) and \( \beta \),

\[
f(\alpha u + \beta v) = f(\alpha u) + f(\beta v) = \alpha f(u) + \beta f(v),
\]

that is, \( f \) preserves linear combinations. Because functions that preserve linear combinations are so important in linear algebra, they are given a special name.

Let \( V \) and \( V' \) be vector spaces. A function \( T : V \to V' \) is called a linear transformation if \( T \) preserves both addition and scalar multiplication, that is, if \( T \) satisfies the following conditions:

1. \( T(u + v) = T(u) + T(v) \)
2. \( T(\alpha v) = \alpha T(v) \)

for all \( u, v \in V \) and all \( \alpha \in \mathbb{R} \). There are some points in connection with these conditions that need to be addressed and that may not be self-evident. Condition 1 states that \( T(u + v) = T(u) + T(v) \) for every two vectors \( u \) and \( v \) of \( V \). Hence, the addition indicated in \( T(u + v) \) takes place in \( V \), while, on the other hand, since \( T(u) \) and \( T(v) \) are vectors in \( V' \), the addition indicated in \( T(u) + T(v) \) takes place in \( V' \). Also, condition 2 states that \( T(\alpha v) = \alpha T(v) \) for every vector \( v \) in \( V \) and every scalar \( \alpha \). By the same reasoning, the scalar multiplication indicated in \( T(\alpha v) \) takes place in \( V \), while the scalar multiplication in \( \alpha T(v) \) takes place in \( V' \). From what we have already seen, every linear transformation preserves linear combinations of vectors (hence, the name).

Let’s consider an example of a linear transformation.

**Result 17.24** The function \( T : \mathbb{R}^3 \to \mathbb{R}^2 \) defined by

\[
T((a, b, c)) = T(a, b, c) = (2a + c, 3c - b)
\]

is a linear transformation.

Before we prove Result 17.24, let’s be certain that we understand what this function does. For example, \( T(1, 2, 3) = (5, 7) \) and \( T(1, -6, -2) = (0, 0) \), while \( T(0, 0, 0) = (0, 0) \). We now show that \( T \) is a linear transformation.

**Proof of Result 17.24** Let \( u, v \in \mathbb{R}^3 \). Then \( u = (a, b, c) \) and \( v = (d, e, f) \) for \( a, b, c, d, e, f \in \mathbb{R} \). Then

\[
T(u + v) = T(a + d, b + e, c + f) = (2(a + d) + c + f, 3(c + f) - (b + e))
\]

\[
= (2a + c, 3c - b) + (2d + f, 3f - e)
\]

\[
= T(a, b, c) + T(d, e, f) = T(u) + T(v)
\]
Chapter 17  Proofs in Linear Algebra

and

\[ T(\alpha \mathbf{u}) = T(\alpha(a, b, c)) = T(\alpha a, \alpha b, \alpha c) \]
\[ = (2\alpha a + \alpha c, 3\alpha c - \alpha b) = \alpha(2a + c, 3c - b) = \alpha T(\mathbf{u}), \]

as desired.

Sometimes the vectors in \( \mathbb{R}^3 \) are written as “column vectors,” that is, as \[
\begin{bmatrix} a \\ b \\ c \end{bmatrix}
\] rather than \((a, b, c)\) or the “row vector” \([a \ b \ c]\). In this case, notice that the linear transformation \(T : \mathbb{R}^3 \rightarrow \mathbb{R}^2\) defined by \(T(a, b, c) = (2a + c, 3c - b)\) can be described as

\[ T(a, b, c) = T \left( \begin{bmatrix} a \\ b \\ c \end{bmatrix} \right) = \begin{bmatrix} 2 & 0 & 1 \\ 0 & -1 & 3 \end{bmatrix} \begin{bmatrix} a \\ b \\ c \end{bmatrix} = \begin{bmatrix} 2a + c \\ -b + 3c \end{bmatrix}. \]

that is, if we let \( \mathbf{v} = \begin{bmatrix} a \\ b \\ c \end{bmatrix} \) and \( A = \begin{bmatrix} 2 & 0 & 1 \\ 0 & -1 & 3 \end{bmatrix} \), then this linear transformation can be defined in terms of the matrix \( A \), namely,

\[ T(\mathbf{v}) = A\mathbf{v}. \]

In general, if \( A \) is an \( m \times n \) matrix, then the function \( T : \mathbb{R}^n \rightarrow \mathbb{R}^m \) defined by \( T(\mathbf{u}) = A\mathbf{u} \) for an \( n \times 1 \) column vector \( \mathbf{u} \in \mathbb{R}^n \) is a linear transformation. For example, consider the \( 3 \times 2 \) matrix \( A = \begin{bmatrix} 1 & -2 \\ 3 & -1 \\ 2 & 5 \end{bmatrix} \). For \( \mathbf{u} = \begin{bmatrix} a \\ b \end{bmatrix} \), \( \mathbf{v} = \begin{bmatrix} c \\ d \end{bmatrix} \) and \( \alpha \in \mathbb{R} \),

\[ T(\mathbf{u} + \mathbf{v}) = T \left( \begin{bmatrix} a + c \\ b + d \end{bmatrix} \right) = \begin{bmatrix} 1 & -2 \\ 3 & -1 \\ 2 & 5 \end{bmatrix} \begin{bmatrix} a + c \\ b + d \end{bmatrix} = \begin{bmatrix} a + c - 2b - 2d \\ 3a + 3c - b - d \\ 2a + 2c + 5b + 5d \end{bmatrix} \]
\[ = \begin{bmatrix} a - 2b \\ 3a - b \\ 2a + 5b \end{bmatrix} + \begin{bmatrix} c - 2d \\ 3c - d \\ 2c + 5d \end{bmatrix} = T \left( \begin{bmatrix} a \\ b \end{bmatrix} \right) + T \left( \begin{bmatrix} c \\ d \end{bmatrix} \right) \]
\[ = T(\mathbf{u}) + T(\mathbf{v}) \]

and

\[ T(\alpha \mathbf{u}) = T \left( \begin{bmatrix} \alpha a \\ \alpha b \end{bmatrix} \right) = \begin{bmatrix} 1 & -2 \\ 3 & -1 \\ 2 & 5 \end{bmatrix} \begin{bmatrix} \alpha a \\ \alpha b \end{bmatrix} = \begin{bmatrix} \alpha a - 2\alpha b \\ 3\alpha a - \alpha b \\ 2\alpha a + 5\alpha b \end{bmatrix} \]
\[ = \alpha \begin{bmatrix} a - 2b \\ 3a - b \\ 2a + 5b \end{bmatrix} = \alpha T \left( \begin{bmatrix} a \\ b \end{bmatrix} \right) = \alpha T(\mathbf{u}). \]

Thus, \( T : \mathbb{R}^2 \rightarrow \mathbb{R}^3 \) is a linear transformation. The proof for a general \( m \times n \) matrix is similar. As another illustration of a linear transformation, we consider a well-known function from \( \mathbb{R}[x] \) to itself.
17.8 Linear Transformations

**Result 17.25** The function \( D \) (for differentiation) from \( \mathbb{R}[x] \) to \( \mathbb{R}[x] \) defined by
\[
D(c_0 + c_1x + c_2x^2 + \cdots + c_nx^n) = c_1 + 2c_2x + \cdots + nc_nx^{n-1}
\]
is a linear transformation.

**Proof** Let \( f, g \in \mathbb{R}[x] \), where \( f(x) = a_0 + a_1x + a_2x^2 + \cdots + a_rx^r \) and \( g(x) = b_0 + b_1x + b_2x^2 + \cdots + b_tx^t \) and, say, \( r \leq s \). Then
\[
D(f(x) + g(x)) = D((a_0 + a_1x + \cdots + a_rx^r) + (b_0 + b_1x + \cdots + b_tx^t))
= D((a_0 + b_0) + (a_1 + b_1)x + \cdots + (a_r + b_r)x^r + b_{r+1}x^{r+1} + \cdots + b_tx^t)
= (a_1 + b_1) + \cdots + r(a_r + b_r)x^{r-1} + (r + 1)b_{r+1}x^r + \cdots + sb_t x^{s-1}
= (a_1 + 2a_2x + \cdots + ra_rx^{r-1}) + (b_1 + 2b_2x + \cdots + sb_t x^{s-1})
= D(f(x)) + D(g(x))
\]
and
\[
D(\alpha f(x)) = D(\alpha a_0 + \alpha a_1x + \alpha a_2x^2 + \cdots + \alpha a_rx^r)
= \alpha a_1 + 2\alpha a_2x + \cdots + r\alpha a_rx^{r-1}
= \alpha(a_1 + 2a_2x + \cdots + ra_rx^{r-1}) = \alpha D(f(x)).
\]
Since \( D \) preserves both addition and scalar multiplication, it is a linear transformation.

There is a special kind a function from a vector space to itself that is always a linear transformation.

**Result 17.26** Let \( V \) be a vector space over the set \( \mathbb{R} \) of real numbers. For \( c \in \mathbb{R} \), the function \( T : V \to V \) defined by \( T(v) = cv \) is a linear transformation.

**Proof** Let \( u, w \in V \). Then
\[
T(u + w) = c(u + w) = cu + cw = T(u) + T(w);
\]
while, for \( \alpha \in \mathbb{R} \),
\[
T(\alpha u) = c(\alpha u) = (c\alpha)(u) = (\alpha c)(u) = \alpha(cu) = \alpha T(u).
\]
Therefore, \( T \) is a linear transformation.

For \( c = 1 \), the function \( T \) defined in Result 17.26 is the identity function, while for \( c = 0 \), the function \( T \) maps every vector into the zero vector. Consequently, both of these functions are linear transformations.

We now look at functions involving other vector spaces. For a function \( f \in \mathcal{F}_\mathbb{R} \) and a real number \( r \), we define the function \( f + r \) by \( (f + r)(x) = f(x) + r \) for all \( x \in \mathbb{R} \).

**Example 17.27** Let \( r \) be a nonzero real number. Prove or disprove: The function \( T : \mathcal{F}_\mathbb{R} \to \mathcal{F}_\mathbb{R} \) defined by \( T(f) = f + r \) is a linear transformation.

**Solution** Let \( f, g \in \mathcal{F}_\mathbb{R} \). Observe that
\[
T(f + g) = (f + g) + r,
\]

Therefore, \( T(f + g) = T(f) + T(g) \) and \( T(cf) = cT(f) \), showing that \( T \) is a linear transformation.
while
\[ T(f) + T(g) = (f + r) + (g + r) = (f + g) + 2r. \]

Since \( r \neq 0 \), it follows that \( T(f + g) \neq T(f) + T(g) \). Therefore, \( T \) is not a linear transformation. ♦

**Example 17.28** Let \( T : M_2(\mathbb{R}) \rightarrow M_2(\mathbb{R}) \) be a function defined by
\[ T \left( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \right) = \begin{bmatrix} ad & 0 \\ 0 & bc \end{bmatrix}. \]
Prove or disprove: \( T \) is a linear transformation.

**Solution** Since
\[ T \left( \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \right) = T \left( \begin{bmatrix} 2 & 2 \\ 2 & 2 \end{bmatrix} \right) = \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} \]
and
\[ 2T \left( \begin{bmatrix} 1 & 1 \\ 1 & 1 \end{bmatrix} \right) = 2 \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ 0 & 2 \end{bmatrix}, \]
\( T \) is not a linear transformation. ♦

**Example 17.29** The function \( T : M_2(\mathbb{R}) \rightarrow M_2(\mathbb{R}) \) is defined by
\[ T \left( \begin{bmatrix} a & b \\ c & d \end{bmatrix} \right) = \begin{bmatrix} a & a \\ c & c \end{bmatrix}. \]
Prove or disprove: \( T \) is a linear transformation.

**Solution** Let \( \begin{bmatrix} a_1 & b_1 \\ c_1 & d_1 \end{bmatrix}, \begin{bmatrix} a_2 & b_2 \\ c_2 & d_2 \end{bmatrix} \in M_2(\mathbb{R}) \) and \( \alpha \in \mathbb{R} \). Then
\[
T \left( \begin{bmatrix} a_1 & b_1 \\ c_1 & d_1 \end{bmatrix} + \begin{bmatrix} a_2 & b_2 \\ c_2 & d_2 \end{bmatrix} \right) = T \left( \begin{bmatrix} a_1 + a_2 & b_1 + b_2 \\ c_1 + c_2 & d_1 + d_2 \end{bmatrix} \right)
\]
\[
= \begin{bmatrix} a_1 + a_2 & a_1 + a_2 \\ c_1 + c_2 & c_1 + c_2 \end{bmatrix} = \begin{bmatrix} a_1 & a_1 \\ c_1 & c_1 \end{bmatrix} + \begin{bmatrix} a_2 & a_2 \\ c_2 & c_2 \end{bmatrix}
\]
\[
= T \left( \begin{bmatrix} a_1 & b_1 \\ c_1 & d_1 \end{bmatrix} \right) + T \left( \begin{bmatrix} a_2 & b_2 \\ c_2 & d_2 \end{bmatrix} \right),
\]
while
\[
T \left( \alpha \begin{bmatrix} a_1 & b_1 \\ c_1 & d_1 \end{bmatrix} \right) = T \left( \begin{bmatrix} \alpha a_1 & \alpha b_1 \\ \alpha c_1 & \alpha d_1 \end{bmatrix} \right) = \begin{bmatrix} \alpha a_1 & \alpha a_1 \\ \alpha c_1 & \alpha c_1 \end{bmatrix}
\]
\[
= \alpha \begin{bmatrix} a_1 & a_1 \\ c_1 & c_1 \end{bmatrix} = \alpha T \left( \begin{bmatrix} a_1 & b_1 \\ c_1 & d_1 \end{bmatrix} \right).
\]
Since \( T \) preserves both addition and scalar multiplication, \( T \) is a linear transformation. ♦
17.9 PROPERTIES OF LINEAR TRANSFORMATIONS

An important property of linear transformations is that the composition of any two linear transformations (when the composition is defined) is also a linear transformation. This fact has an interesting consequence, as we shall see.

Theorem 17.30 Let $V$, $V'$ and $V''$ be vector spaces. If $T_1 : V \to V'$ and $T_2 : V' \to V''$ are linear transformations, then the composition $T_2 \circ T_1 : V \to V''$ is a linear transformation as well.

Proof For $u, v \in V$ and a scalar $\alpha$, observe that

$$(T_2 \circ T_1)(u + v) = T_2(T_1(u + v)) = T_2(T_1(u) + T_1(v)) = (T_2 \circ T_1)(u) + (T_2 \circ T_1)(v)$$

and

$$(T_2 \circ T_1)(\alpha v) = T_2(T_1(\alpha v)) = T_2(\alpha T_1(v)) = \alpha T_2(T_1(v)) = \alpha (T_2 \circ T_1)(v).$$

Therefore, $T_2 \circ T_1$ is a linear transformation.

As an example of the preceding theorem, let $T_1 : \mathbb{R}^3 \to \mathbb{R}^2$ and $T_2 : \mathbb{R}^2 \to \mathbb{R}^3$ be linear transformations defined by

$$T_1(a, b, c) = (a + 2b - c, 3b + 2c)$$

and

$$T_2(a, b) = (b, 2a, a + b).$$

Then $T_2 \circ T_1 : \mathbb{R}^3 \to \mathbb{R}^3$ is given by

$$(T_2 \circ T_1)(a, b, c) = T_2(T_1(a, b, c)) = T_2(a + 2b - c, 3b + 2c) = (3b + 2c, 2a + 4b - 2c, a + 5b + c).$$

From what we mentioned earlier, $T_1$ and $T_2$ can also be defined by

$$T_1 \left( \begin{array}{c} a \\ b \\ c \end{array} \right) = \left[ \begin{array}{ccc} 1 & 2 & -1 \\ 0 & 3 & -2 \end{array} \right] \left[ \begin{array}{c} a \\ b \\ c \end{array} \right]$$

and

$$T_2 \left( \begin{array}{c} a \\ b \end{array} \right) = \left[ \begin{array}{cc} 0 & 1 \\ 2 & 0 \\ 1 & 1 \end{array} \right] \left[ \begin{array}{c} a \\ b \end{array} \right].$$

Interestingly enough,

$$T_2 \circ T_1 \left( \begin{array}{c} a \\ b \\ c \end{array} \right) = \left[ \begin{array}{ccc} 0 & 1 & 2 \\ 2 & 0 & 3 \\ 1 & 1 & -2 \end{array} \right] \left[ \begin{array}{c} a \\ b \\ c \end{array} \right];$$

that is, the composition $T_2 \circ T_1$ can be obtained by multiplying the matrices that describe $T_1$ and $T_2$. Therefore, if we represent the linear transformations $T_1$ and $T_2$ by matrices $A_1$ and $A_2$, respectively, then the matrix that represents $T_2 \circ T_1$ is $A_2A_1$. This also explains why the definition of matrix multiplication, though curious at first, is actually quite logical.

Two fundamental properties of a linear transformation are given in the next theorem.
Chapter 17  Proofs in Linear Algebra

Theorem 17.31  Let \( V \) and \( V' \) be vector spaces with respective zero vectors \( z \) and \( z' \). If \( T : V \rightarrow V' \) is a linear transformation, then

\[
\begin{align*}
(i) \quad & T(z) = z' \\
(ii) \quad & T(-v) = -T(v) \text{ for all } v \in V.
\end{align*}
\]

Proof  We first verify \((i)\). Since \( T \) preserves scalar multiplication,

\[ T(z) = T(0z) = 0T(z) = z'. \]

Next we verify \((ii)\). Let \( v \in V \). Then

\[ T(v) + T(-v) = T(v + (-v)) = T(z) = z', \]

the last equality following by \((i)\). Since the vector \( T(v) \) in \( V' \) has a unique negative, namely \(-T(v)\), we conclude that \( T(-v) = -T(v) \). \[\]

If \( T : V \rightarrow V' \) is a linear transformation, then it is often of interest to know how \( T \) acts on subspaces of \( V \). Let’s recall some terminology and notation from functions. In a linear transformation \( T : V \rightarrow V' \), the set \( V \) is the domain of \( T \) and the set \( V' \) is the codomain of \( T \). If \( W \) is a subset of \( V \), then \( T(W) = \{ T(w) : w \in W \} \) is the image of \( W \) under \( T \). In particular, \( T(V) \) is the range of \( T \).

Theorem 17.32  Let \( V \) and \( V' \) be vector spaces and let \( T : V \rightarrow V' \) be a linear transformation. If \( W \) is a subspace of \( V \), then \( T(W) \) is a subspace of \( V' \).

Proof  Let \( z \) and \( z' \) be the zero vectors in \( V \) and \( V' \), respectively. Since \( z \in W \) and \( T(z) = z' \) by Theorem 17.31, it follows that \( z' \in T(W) \) and so \( T(W) \neq \emptyset \). Thus, we need only show that \( T(W) \) is closed under addition and scalar multiplication. Let \( u \) and \( v \) be two vectors in \( T(W) \). Hence, there exist vectors \( u \) and \( v \) in \( W \) such that \( T(u) = u \) and \( T(v) = v \). Then

\[ u + v = T(u) + T(v) = T(u + v). \]

Since \( u, v \in W \) and \( W \) is a subspace of \( V \), it follows that \( u + v \in W \). Hence, \( u + v = T(u + v) \in T(W) \).

Next let \( \alpha \) be a scalar and \( x \in T(W) \). We show that \( \alpha x \in T(W) \). Since \( x \in T(W) \), there exists \( u \in W \) such that \( T(u) = x \). Now,

\[ \alpha x = \alpha T(u) = T(\alpha u). \]

Since \( \alpha u \in W \), it follows that \( \alpha x = T(\alpha u) \in T(W) \). By the Subspace Test, \( T(W) \) is a subspace of \( V' \). \[\]

To illustrate Theorem 17.32, let’s return to the linear transformation \( T : \mathbb{R}^3 \rightarrow \mathbb{R}^2 \) defined in Result 17.24 by \( T(a, b, c) = (2a + c, 3c - b) \). Let \( W = \{(a, b, 0) : a, b \in \mathbb{R} \} \). We use the Subspace Test to show that \( W \) is a subspace of \( \mathbb{R}^3 \). Since \( (0, 0, 0) \in W \), it follows that \( W \neq \emptyset \). Let \( (a_1, b_1, 0), (a_2, b_2, 0) \in W \) and let \( \alpha \in \mathbb{R} \). Then

\[
(a_1, b_1, 0) + (a_2, b_2, 0) = (a_1 + a_2, b_1 + b_2, 0) \in W \quad \text{and} \quad \alpha(a_1, b_1, 0) = (\alpha a_1, \alpha b_1, 0) \in W.
\]

Since \( W \) is closed under addition and scalar multiplication, \( W \) is a subspace of \( \mathbb{R}^3 \). By Theorem 17.32, \( T(W) = \{(2a, -b) : a, b \in \mathbb{R} \} \) is a subspace of \( \mathbb{R}^2 \). We show in fact
Exercises for Chapter 17

Theorem 17.33 Let $V$ and $V'$ be vector spaces and let $T : V \to V'$ be a linear transformation. Then the kernel of $T$ is a subspace of $V$.

Proof Let $z$ and $z'$ be the zero vectors of $V$ and $V'$, respectively. Since $T(z) = z'$, it follows that $z \in \ker(T)$ and so $\ker(T) \neq \emptyset$. Now let $u, v \in \ker(T)$ and $\alpha \in \mathbb{R}$. Then

$$T(u + v) = T(u) + T(v) = z' + z' = z'$$

and

$$T(\alpha u) = \alpha T(u) = \alpha z' = z'.$$

This implies that $u + v \in \ker(T)$ and $\alpha u \in \ker(T)$. By the Subspace Test, $\ker(T)$ is a subspace of $V$.

Returning once again to the linear transformation $T : \mathbb{R}^3 \to \mathbb{R}^2$ in Result 17.24 defined by $T(a, b, c) = (2a + c, 3c - b)$, we see that

$$\ker(T) = \{(a, b, c) : 2a + c = 0 \text{ and } 3c - b = 0\}$$

is a subspace of $\mathbb{R}^3$. Since $2a + c = 0$ and $3c - b = 0$, it follows that $a = -c/2$ and $b = 3c$. Thus, $\ker(T) = \{(-c/2, 3c, c) : c \in \mathbb{R}\}$. In other words, $\ker(T)$ is the subspace of $\mathbb{R}^3$ consisting of all scalar multiples of $(-1/2, 3, 1)$.

EXERCISES FOR CHAPTER 17

17.1. Prove that the set $C = \{(a + bi) : a, b \in \mathbb{R}\}$ of complex numbers is a vector space under the addition $(a + bi) + (c + di) = (a + c) + (b + d)i$ and scalar multiplication $\alpha(a + bi) = \alpha a + \alpha bi$, where $\alpha \in \mathbb{R}$.

17.2. Although we have taken $\mathbb{R}$ to be the set of scalars in a vector space, this need not always be the case. Let $V = \{([a], [b]) : [a], [b] \in \mathbb{Z}_3\}$ and let $\mathbb{Z}_3$ be the set of scalars.
Chapter 17  Proofs in Linear Algebra

(a) Show that $V$ is a vector space over the set $\mathbb{Z}_3$ of scalars under the addition $([a], [b]) + ([c], [d]) = ([a + c], [b + d])$ and scalar multiplication $[k]([a], [b]) = ([ka], [kb])$.

(b) Write out precisely the elements of $V$. (Hence, a vector space can have more than one vector and be finite.)

17.3. Addition or scalar multiplication is defined in $\mathbb{R}^2$ in each of the following. (Each operation not defined is taken as the standard one.) Under these operations, determine whether $\mathbb{R}^2$ is a vector space.

(a) $(a, b, c) + (d, e, f) = (a, b, c)$
(b) $(a, b, c) + (d, e, f) = (a - d, b - e, c - f)$
(c) $(a, b, c) + (d, e, f) = (0, 0, 0)$
(d) $\alpha(a, b, c) = (a, b, c)$
(e) $\alpha(a, b, c) = (b, c, a)$
(f) $\alpha(a, b, c) = (0, 0, 0)$
(g) $\alpha(a, b, c) = (aa, 3ab, ac)$

17.4. Let $V$ be a vector space, where $u, v \in V$. Prove that there exists a unique vector $x$ in $V$ such that $u + x = v$.

17.5. Let $V$ be a vector space with $v \in V$ and $\alpha \in \mathbb{R}$. Prove that $\alpha(-v) = (-\alpha)v = -(\alpha v)$.

17.6. (a) Let $V$ be a vector space and $u, v, w \in V$. Prove that if $u + v = u + w$, then $v = w$. (This is the cancellation property for addition of vectors.)

(b) Use (a) to prove Theorem 17.3.

17.7. Prove or disprove:
(a) No vector is its own negative.
(b) Every vector is the negative of some vector.
(c) Every vector space has at least two vectors.

17.8. Let $V$ be a vector space containing nonzero vectors $u$ and $v$. Prove that if $u \neq \alpha v$ for each $\alpha \in \mathbb{R}$, then $u \neq \beta(u + v)$ for each $\beta \in \mathbb{R}$.

17.9. Determine which of the following subsets of $\mathbb{R}^4$ are subspaces of $\mathbb{R}^4$.

(a) $W_1 = \{(a, a, a, a) : a \in \mathbb{R}\}$
(b) $W_2 = \{(a, 2b, 3a, 4b) : a, b \in \mathbb{R}\}$
(c) $W_3 = \{(a, 0, 0, 1) : a \in \mathbb{R}\}$
(d) $W_4 = \{(a, a^2, 0, 0) : a \in \mathbb{R}\}$
(e) $W_5 = \{(a, b, a + b, b) : a, b \in \mathbb{R}\}$

17.10. Let $\mathcal{F}_\mathbb{R}$ be the vector space of all functions from $\mathbb{R}$ to $\mathbb{R}$. Determine which of the following subsets of $\mathcal{F}_\mathbb{R}$ are subspaces of $\mathcal{F}_\mathbb{R}$.

(a) $W_1$ consists of all functions $f$ such that $f(1) = 0 = f(2)$.
(b) $W_2$ consists of all functions $f$ such that $f(1) = 0$ or $f(2) = 0$.
(c) $W_3$ consists of all functions $f$ such that $f(2) = 2f(1)$.
(d) $W_4$ consists of all functions $f$ such that $f(1) \neq f(2)$.
(e) $W_5$ consists of all functions $f$ such that $f(1) \neq 0$.

17.11. Recall that the set $\mathbb{R}[x]$ of polynomial functions is a subspace of $\mathcal{F}_\mathbb{R}$. Now determine which of the following subsets of $\mathbb{R}[x]$ are subspaces of $\mathbb{R}[x]$.

(a) $U_1 = \{f : f(x) = a \text{ for a fixed real number } a\}$ (The set of all constant polynomials)
(b) $U_2 = \{f : f(x) = ax^2 + bx^2 + dx, a, b, c, d \in \mathbb{R}, d \neq 0\}$
Exercises for Chapter 17

17.12. Let $M_2(\mathbb{R})$ be the vector space of $2 \times 2$ matrices whose entries are real numbers. Determine which of the following subsets of $M_2(\mathbb{R})$ are subspaces of $M_2(\mathbb{R})$.

(a) $W = \left\{ \begin{bmatrix} a & b \\ c & d \end{bmatrix} : \quad ad - bc = 0 \right\}$

(b) $W = \left\{ \begin{bmatrix} a & b \\ c & d \end{bmatrix} : \quad \alpha_1a + \alpha_2b + \alpha_3c + \alpha_4d = 0 \right\}$, where $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ are fixed real numbers.

17.13. Prove that

$$W = \left\{ \begin{bmatrix} a_1 & a_2 & a_3 \\ 0 & a_4 & a_5 \\ 0 & 0 & a_6 \end{bmatrix} : \quad a_i \in \mathbb{R} \quad \text{for} \quad 1 \leq i \leq 6 \right\}$$

is a subspace of the vector space $M_3(\mathbb{R})$.

17.14. Let $U$ and $W$ be subspaces of a vector space $V$. Prove that $U \cap W$ is a subspace of $V$.

17.15. The graph of the function $f : \mathbb{R} \rightarrow \mathbb{R}$ defined by $f(x) = \frac{2}{3}x$ is a straight line in $\mathbb{R}^2$ passing through the origin. Each point $(x, y)$ on this graph is a solution of the equation $3x - 5y = 0$. Prove that the set $S$ of solutions of this equation is a subspace of $\mathbb{R}^2$.

17.16. Determine the following linear combinations:

(a) $4 \cdot (1, -2, 3) + (-2) \cdot (1, -1, 0)$

(b) $(-1) \begin{bmatrix} 3 \\ 1 \\ -2 \end{bmatrix} + 2 \begin{bmatrix} 1 \\ 1 \\ 2 \end{bmatrix} + 5 \begin{bmatrix} -1 \\ 1 \\ -1 \end{bmatrix}$

17.17. In $\mathbb{R}^3$, write $i = (1, 0, 0)$ as a linear combination of $u_1 = (0, 1, 1), u_2 = (1, 0, 1)$ and $u_3 = (1, 1, 0)$.

17.18. Let $u = (1, 2, 3), v = (0, 1, 2)$ and $w = (3, 1, -1)$ be vectors in $\mathbb{R}^3$.

(a) Show that $w$ can be expressed as a linear combination of $u$ and $v$.

(b) Show that the vector $x = (8, 5, 2)$ can be expressed as a linear combination of $u, v$ and $w$ in more than one way.

17.19. Let $V$ be a vector space containing the vectors $v_1, v_2, \ldots, v_n$ and the vectors $w_1, w_2, \ldots, w_m$. Let $W = \langle v_1, v_2, \ldots, v_n \rangle$ and $W' = \langle w_1, w_2, \ldots, w_m \rangle$. Prove that if each vector $v_i$ ($1 \leq i \leq n$) is a linear combination of the vectors $w_1, w_2, \ldots, w_m$, then $W \subseteq W'$.

17.20. Prove that $\langle (1, 2, 3), (0, 4, 1) \rangle = \langle (1, 6, 4), (1, -2, 2) \rangle$ in $\mathbb{R}^3$.

17.21. Let $V$ be a vector space containing the vectors $u$ and $v$. Prove that

(a) $\langle u, v \rangle = \langle u, 2u + v \rangle$.

(b) $\langle u, v \rangle = \langle u + v, u - v \rangle$.

17.22. Determine which sets $S$ of vectors are linearly independent in the indicated vector space $V$.

(a) $S = \{(1, 1, 1), (1, -2, 3), (2, 5, -1)\}; \quad V = \mathbb{R}^3$.

(b) $S = \{(1, 0, -1), (2, 1, 1), (0, 1, 3)\}; \quad V = \mathbb{R}^3$.

(c) $S = \left\{ \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}, \begin{bmatrix} 1 & 2 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 0 & 1 \\ 0 & 1 \end{bmatrix} \right\}; \quad V = M_2(\mathbb{R})$. 
17.23. For the vectors $\mathbf{u} = (1, 1, 1)$ and $\mathbf{v} = (1, 0, 2)$, find a vector $\mathbf{w}$ such that $\mathbf{u}, \mathbf{v}, \mathbf{w}$ are linearly independent in $\mathbb{R}^3$. Verify that $\mathbf{u}, \mathbf{v}, \mathbf{w}$ are linearly independent.

17.24. Prove or disprove: If $\mathbf{u}_1, \mathbf{u}_2, \mathbf{u}_3$ are linearly independent vectors in a vector space $V$, then $\mathbf{u}_1 + \mathbf{u}_2, \mathbf{u}_1 + \mathbf{u}_3, 2\mathbf{u}_3$ are linearly independent vectors in $V$.

17.25. Determine which ones $S$ of vectors in $\mathcal{F}_\mathbb{R}$ are linearly independent.

(a) $S = \{1, \sin^2 x, \cos^2 x\}$
(b) $S = \{1, \sin x, \cos x\}$
(c) $S = \{1, e^x, e^{-x}\}$
(d) $S = \{1, x, x/(x^2 + 1)\}$.

17.26. Let $S = \{\mathbf{u}_1, \mathbf{u}_2, \ldots, \mathbf{u}_n\}$ be a linearly dependent set of $n \geq 2$ vectors in a vector space $V$. Prove that if each subset of $S$ consisting of $n - 1$ vectors is linearly independent, then there exist nonzero scalars $c_1, c_2, \ldots, c_n$ such that $c_1\mathbf{u}_1 + c_2\mathbf{u}_2 + \cdots + c_n\mathbf{u}_n = \mathbf{0}$.

17.27. Prove that if $T : V \to V'$ is a linear transformation, then

$$T(\mathbf{v}_1 + \alpha_2\mathbf{v}_2 + \cdots + \alpha_n\mathbf{v}_n) = \mathbf{v}_1T(\mathbf{v}_1) + \alpha_2T(\mathbf{v}_2) + \cdots + \alpha_nT(\mathbf{v}_n),$$

where $\mathbf{v}_1, \mathbf{v}_2, \ldots, \mathbf{v}_n \in V$ and $\alpha_1, \alpha_2, \ldots, \alpha_n \in \mathbb{R}$.

17.28. Let $V$ and $V'$ be vector spaces and let $T : V \to V'$ be a linear transformation. Prove that if $W'$ is a subspace of $V'$, then $T^{-1}(W')$ is a subspace of $V$.

17.29. Prove that there exists a bijective linear transformation $T : \mathbb{R}^2 \to \mathbb{C}$, where $\mathbb{C} = \{a + bi : a, b \in \mathbb{R}\}$ is the set of complex numbers.

17.30. For vector spaces $V$ and $V'$, let $T_1$ and $T_2$ be linear transformations from $V$ to $V'$. Define $T_1 + T_2 : V \to V'$ as

$$(T_1 + T_2)(\mathbf{v}) = T_1(\mathbf{v}) + T_2(\mathbf{v}).$$

Prove that $T_1 + T_2$ is also a linear transformation.

17.31. Let $W = \left\{ \begin{bmatrix} a & b \\ 0 & a + b \end{bmatrix} : a, b \in \mathbb{R} \right\}$.

(a) Prove that $W$ is a subspace of $M_2(\mathbb{R})$.
(b) Prove that there exists a bijective linear transformation $T : \mathbb{R}^2 \to W$.

17.32. For the $2 \times 3$ matrix $A = \begin{bmatrix} 3 & 1 & -1 \\ 2 & -5 & 2 \end{bmatrix}$, a function $T : \mathbb{R}^3 \to \mathbb{R}^2$ is defined by $T(\mathbf{u}) = A\mathbf{u}$, where $\mathbf{u}$ is a $3 \times 1$ column vector in $\mathbb{R}^3$.

(a) Determine $T(\mathbf{u})$ for $\mathbf{u} = \begin{bmatrix} 4 \\ -1 \\ -2 \end{bmatrix}$.
(b) Prove that $T$ is a linear transformation.

17.33. Let $D : \mathbb{R}[x] \to \mathbb{R}[x]$ be the differentiation linear transformation defined by

$$D(c_0 + c_1x + \cdots + c_nx^n) = c_1 + 2c_2x + \cdots + nc_nx^{n-1}.$$ Determine each of the following.

(a) $D(W)$, where $W = \{a + bx : a, b \in \mathbb{R}\}$.
(b) $D(W)$, where $W = \mathbb{R}$.
(c) $\ker(D)$. 

17.34. Let $T : M_2(\mathbb{R}) \rightarrow M_2(\mathbb{R})$ be the linear transformation defined by

$$T\left(\begin{bmatrix} a & b \\ c & d \end{bmatrix}\right) = \begin{bmatrix} a & a \\ c & c \end{bmatrix}$$

and consider the subset $W = \left\{ \begin{bmatrix} a & 0 \\ 0 & d \end{bmatrix} : a, d \in \mathbb{R} \right\}$ of $M_2(\mathbb{R})$.

(a) Prove that $W$ is a subspace of $M_2(\mathbb{R})$.

(b) Determine the subspace $T(W)$ of $M_2(\mathbb{R})$.

(c) Determine the subspace $\ker(T)$ of $M_2(\mathbb{R})$.

17.35. For the following statement $S$ and proposed proof, either (1) $S$ is true and the proof is correct, (2) $S$ is true and the proof is incorrect or (3) $S$ is false and the proof is incorrect. Explain which of these occurs.

$S$: Let $V$ be a vector space. If $u$ is a vector of $V$ such that $u + v = v$ for some $v \in V$, then $u + v = v$ for all $v \in V$.

Proof Assume that $u + v = v$ for some $v \in V$. Then we also know that $z + v = v$, where $z$ is the zero vector of $V$. Hence, $u + v = z + v$. By Exercise 17.6, $u = z$ and so $u + v = v$ for all $v \in V$. $\blacksquare$
Proofs with Real and Complex Numbers

While we have encountered the integers and rational numbers often throughout our discussions and the real numbers to a somewhat lesser degree, there are many areas of mathematics for which it is the real numbers that are of primary interest to us. There are properties possessed by the real numbers that the integers and rational numbers do not have. However, as we will see, the rational and real numbers have many properties in common. Many properties of the real numbers were described and verified in Section 4.3. In fact, it was the real numbers we encountered most often in Chapter 14 when studying proofs in calculus. In this chapter, we will describe properties possessed by the real numbers – and only by the real numbers.

Real numbers have been encountered in more elementary mathematics as roots of polynomials with real coefficients. However, we have seen polynomial equations with real number coefficients that have no real number roots. This characteristic of the real numbers does not occur with the complex numbers; that is, every polynomial equation with complex number coefficients has only roots that are real or complex numbers.

Our goal in this chapter then is to discuss these two important classes of numbers – the real numbers and the complex numbers.

18.1 THE REAL NUMBERS AS AN ORDERED FIELD

Interest in real numbers can no doubt be traced back many centuries to measurement, magnitude and distance as these numbers were needed to answer questions of the type “How much . . .”, “How many . . .” and “How far . . .” In mathematics, however, our interest in real numbers relies more on certain properties they possess. First, we recall some of the basic properties of real numbers.

A fundamental characteristic of real numbers concerns the fact that they can be added and multiplied, always resulting in a real number, and that these two operations lead to several basic properties possessed by this important set of numbers. That is, addition + and multiplication · are binary operations (if \( a, b \in \mathbb{R} \), then \( a + b \in \mathbb{R} \) and \( ab = a \cdot b \in \mathbb{R} \)). In particular, the real numbers satisfy the following properties.

The fact that $\mathbb{R}$ satisfies properties 1–9 above means that $\mathbb{R}$ is a field (an algebraic structure described in Chapter 16). There are fields distinct from the real numbers, however. For example, the set $\mathbb{Q}$ of rational numbers and the set $\mathbb{Z}_p$ of integers modulo a prime $p$ are fields. The field $\mathbb{Z}_p$ is finite, of course, since it consists of $p$ elements, while the field $\mathbb{Q}$ is denumerable and the field $\mathbb{R}$ is uncountable (see Section 11.3). Unlike the field $\mathbb{Z}_p$ of integers modulo a prime $p$, the real numbers (and rational numbers as well) have two properties (called properties of order) that allow us to talk about positive real numbers and negative real numbers.

### Properties of Order

10. Every real number $a$ satisfies exactly one of the following: $a > 0$, $a = 0$, $a < 0$.

11. If $a, b \in \mathbb{R}$ such that $a > 0$ and $b > 0$, then $a + b > 0$ and $ab > 0$.

Of course, $a \geq 0$ tells us that $a > 0$ or $a = 0$, and $b \leq 0$ tells us that $b < 0$ or $b = 0$. For two real numbers $a$ and $b$, we write $a > b$, as expected, to mean $a - b > 0$. We may also write $a > b$ as $b < a$.

That the field $\mathbb{R}$ satisfies properties 10 and 11 means that $\mathbb{R}$ is an ordered field. The set $\mathbb{Q}$ of rational numbers is also an ordered field. The field $\mathbb{Z}_2$, consisting only of
the two elements \([0]\) and \([1]\), is not an ordered field. If \(\mathbb{Z}_2\) were an ordered field, then by property 10, either \([1] > [0]\) or \([1] < [0]\). If \([1] > [0]\), then \([1] + [1] = [0] > [0]\) by property 11, which is impossible. On the other hand, if \([1] < [0]\), then \([0] > [1]\) and so \([0] - [1] = [0] + (-[1]) = [0] + [1] = [1] > [0]\), again impossible.

Result 18.1 If \(a, b, c\) and \(d\) are real numbers such that \(a > b\) and \(c > d\), then \(ac + bd > ad + bc\).

Proof Since \(a > b\) and \(c > d\), it follows that \(a - b > 0\) and \(c - d > 0\). Therefore, by property 11,

\[(a - b)(c - d) = ac + bd - (ad + bc) > 0.\]

Hence, \(ac + bd > ad + bc\).

While we have seen that the set \(\mathbb{R}\) of real numbers is an ordered field, this property of \(\mathbb{R}\) is not enough to distinguish it from all other fields since \(\mathbb{Q}\) as well is an ordered field. We now consider an additional property possessed by real numbers that no other ordered field has.

### 18.2 The Real Numbers and the Completeness Axiom

Let \(S\) be a nonempty subset of \(\mathbb{R}\). A real number \(b\) is said to be an upper bound for \(S\) if \(x \leq b\) for all \(x \in S\). A real number \(a\) is said to be a lower bound for \(S\) if \(a \leq x\) for all \(x \in S\). A set of real numbers having both an upper and lower bound is called a bounded set. A set that is not bounded is called an unbounded set. For example, the interval \((0, 1)\) is a bounded set. Every number \(b \geq 1\) is an upper bound. The set \(\mathbb{N}\) has lower bounds. In fact, any number \(a \leq 1\) is a lower bound for \(\mathbb{N}\).

A real number \(d\) is a least upper bound or supremum for \(S\) if \(d\) is an upper bound of \(S\) and \(d \leq b\) for every upper bound \(b\) of \(S\). A real number \(c\) is a greatest lower bound or infimum for \(S\) if \(c\) is a lower bound of \(S\) and \(c \geq a\) for every lower bound \(a\) of \(S\). While a set of real numbers with an upper bound has infinitely many upper bounds, this is not the case with least upper bounds. The same is true for lower bounds and greatest lower bounds.

Theorem 18.2 Every subset \(S\) of real numbers having a least upper bound has a unique least upper bound. Also, if \(S\) has a greatest lower bound, then it is unique as well.

Proof Assume that some subset \(S\) of real numbers has two least upper bounds, say \(b_1\) and \(b_2\). Since \(b_1\) is a least upper bound, \(b_1 \leq b_2\); while since \(b_2\) is a least upper bound, \(b_2 \leq b_1\). Therefore, \(b_1 = b_2\).

The proof of the uniqueness of a greatest lower bound is similar.

The unique least upper bound (unique supremum) for a set \(S\) of real numbers is denoted by \(\text{lub}(S)\) or \(\text{sup}(S)\). Furthermore, the unique greatest lower bound (unique infimum) for a set \(S\) of real numbers is denoted by \(\text{glb}(S)\) or \(\text{inf}(S)\).

If an upper bound \(b\) for a set \(S\) of real numbers belongs to \(S\), then \(b = \text{sup}(S)\) and \(b\) is the greatest or maximum element of \(S\). If a lower bound \(a\) for \(S\) belongs to \(S\), then
4 Chapter 18 Proofs with Real and Complex Numbers

$a = \inf(S)$ and $a$ is the least or minimum element of $S$. Should $S$ have these elements, then the maximum element of $S$ is denoted by $\max(S)$ and the minimum element of $S$ is denoted by $\min(S)$. Certainly, if $S$ is a finite nonempty set of real numbers, then $S$ has both a maximum element and minimum element. The contrapositive of this statement then says: If $S$ is a nonempty set of real numbers having either no maximum element or no minimum element, then $S$ is an infinite set.

Example 18.3
(a) The set $S = \{x \in \mathbb{R} : 0 \leq x < 1\} = [0, 1)$ has 1 as an upper bound and 0 as a lower bound. In fact, 1 is the supremum of $S$ (and so $\sup(S) = 1$) while 0 is the infimum (and so $\inf(S) = 0$). In addition, $\min(S) = 0$, while $S$ has no maximum element.
(b) The set $\mathbb{R}^+$ of positive real numbers has no upper bound and 0 is the infimum of $\mathbb{R}^+$ (and so $\inf(\mathbb{R}^+) = 0$). This set has no maximum or minimum element.
(c) The set $S = \{x \in \mathbb{Q} : \sqrt{2} < x < \sqrt{3}\}$ has the rational number 2 as an upper bound and 1 as a lower bound. It turns out for any $M \in \mathbb{Q}$ that is an upper bound for $S$, there is an upper bound $M' \in \mathbb{Q}$ for $S$ such that $M' < M$ and so $S$ has no least upper bound in $\mathbb{Q}$. Also, $S$ has no greatest lower bound in $\mathbb{Q}$.

Example 18.4 For each of the following sets $S$ of real numbers, determine $\sup(S)$ and $\inf(S)$ should these exist. Also determine $\max(S)$ and $\min(S)$ if these exist.

(a) $S = \{-1, 3, 5, \pi^2, 8\}$
(b) $S = \{\frac{1}{n} : n \in \{1, 2, \ldots, 100\}\}$
(c) $S = \{x \in \mathbb{R} : x < 3\}$
(d) $S = \{x \in \mathbb{Q} : -1 \leq x \leq \sqrt{2}\}$.

Solution
(a) $\sup(S) = \max(S) = \pi^2$, $\inf(S) = \min(S) = -1$.
(b) $\sup(S) = \max(S) = 1$, $\inf(S) = \min(S) = 1/100$.
(c) $\sup(S) = 3$ while $\max(S)$ does not exist. The set $S$ has no lower bound.
(d) $\sup(S) = \sqrt{2}$ but $\max(S)$ does not exist, while $\inf(S) = \min(S) = -1$.

There is another important property possessed by the real numbers. While this property may seem self-evident, it cannot, however, be proved by means of the definitions and properties we have stated. Consequently, we accept this as an axiom for the real numbers.

The Completeness Axiom Every nonempty set of real numbers having an upper bound in $\mathbb{R}$ has a least upper bound in $\mathbb{R}$.

With this additional axiom, $\mathbb{R}$ now takes on the added structure of a complete ordered field. As with other algebraic structures, there is a concept of isomorphism for complete ordered fields. Here, it turns out that every complete ordered field is isomorphic to $\mathbb{R}$. Consequently, there is essentially only one complete ordered field, namely the real numbers. Therefore, the defining properties of a complete ordered field provide a characterization of the real numbers. We observed in Example 18.3(c) that the set $S = \{x \in \mathbb{Q} : \sqrt{2} < x < \sqrt{3}\}$ has upper bounds in $\mathbb{Q}$ but no least upper bound in $\mathbb{Q}$. Therefore, the set $\mathbb{Q}$ of rational numbers is an example of an ordered field that is not a complete ordered field.
We saw in Theorem 5.16 that the number $\sqrt{2}$ is not rational; that is, there is no rational number $r$ for which $r^2 = 2$. This, however, brings up an even more fundamental question – one that may not even have occurred to us. How do we know that there is any real number $r$, rational or not, such that $r^2 = 2$? We are now in a position to verify this.

**Theorem 18.5** The real number $\sqrt{2}$ exists, that is, there is a real number $r$ for which $r^2 = 2$.

**Proof** Let $S = \{x \in (0, \infty) : x^2 < 2\}$. Since 1, for example, belongs to $S$, the set $S$ is nonempty. Also, since every real number $x \in S$ has the property that $x^2 < 4 = 2^2$, it follows that $x < 2$ for each $x \in S$ and so 2 is an upper bound for $S$. By the Completeness Axiom, $S$ has a least upper bound, say sup($S$) = $a$. We claim that $a^2 = 2$. Assume, to the contrary, that $a^2 \neq 2$. There are then two possibilities for $a$.

*Case 1. $a^2 < 2$.* Let $b = 2/a$ and so $ab = 2$. Since $a^2 < 2$, it follows that $a = a^2/a < 2/a = b$. We show that there is a real number greater than $a$ that belongs to $S$, which will contradict the fact that $a$ is a least upper bound of $S$.

Let $c$ be the arithmetic mean (average) of $a$ and $b$, that is, $c = (a + b)/2$. Thus, $a < c < b$. Since $a \neq b$, it follows that $(a - b)^2 > 0$ and so $(a - b)^2 = a^2 - 2ab + b^2 > 0$. Thus, $a^2 + 2ab + b^2 > 4ab$ and so $(a + b)^2 > 4ab$. Hence,

$$c^2 = \left(\frac{a + b}{2}\right)^2 > ab = 2 \text{ and so } \left(\frac{c}{2}\right)^2 > \frac{1}{2}.$$ 

Therefore,

$$\left(\frac{2}{c}\right)^2 < 2$$

and so $\frac{2}{c} \in S$. Since $\frac{c}{2} < \frac{b}{2}$, it follows that $\frac{2}{c} > \frac{2}{b} = a$, which is impossible since $a$ is an upper bound of $S$.

*Case 2. $a^2 > 2$.* As in Case 1, we let $b = 2/a$ and $c = (a + b)/2$. Here, we have $a = a^2/a > 2/a = b$ and so $b < c < a$. Applying the same argument as in Case 1, we have $c^2 > 2$ again. For each $x \in S$, it follows that $x^2 < 2 < c^2$, which implies that $x < c$. That is, $c$ is an upper bound for $S$. Since $c < a$ and sup($S$) = $a$, we have a contradiction here as well. ■

Since $\mathbb{R}$ satisfies the Completeness Axiom, it not only follows that every set of real numbers having an upper bound in $\mathbb{R}$ has a least upper bound in $\mathbb{R}$ but it has the analogous property for lower bounds.

**Theorem 18.6** Every nonempty set of real numbers having a lower bound in $\mathbb{R}$ has a greatest lower bound in $\mathbb{R}$.

**Proof** Let $S$ be a nonempty set of real numbers having $a \in \mathbb{R}$ as a lower bound for $S$. Therefore, $a \leq x$ for every $x \in S$. Let $T = \{-x : x \in S\}$. Since $a \leq x$, it follows that $-a \geq -x$ for every element $-x \in T$. Therefore, $-a$ is an upper bound for $T$. By the Completeness Axiom, $T$ has a least upper bound $b$. Therefore, $-a \geq b \geq -x$ and so $a \leq -b \leq x$. That is, $-b$ is a lower bound for $S$ and is at least as large as every lower bound for $S$. Hence, $-b$ is the greatest lower bound for $S$. ■
Among the many properties of the real numbers is a simple-sounding, yet nevertheless useful, property called the **Archimedean Principle**. This is named for the ancient Greek geometer and physicist Archimedes of Syracuse. This principle appears in Book V of Euclid’s classic *Elements*. It is sometimes referred to as the Axiom of Archimedes, but this is doubly misleading, as it is not an axiom since it is a consequence of the Completeness Axiom and is not due to Archimedes (in fact, Archimedes credits it to Eudoxus of Cnidus).

**Theorem 18.7** (The Archimedean Principle) For every real number \( x \), there exists a positive integer \( n \) such that \( x < n \).

**Proof** If \( x \leq 0 \), then \( n = 1 \) has the desired property. Hence, we may assume that \( x \) is positive. Let \( S = \{ k \in \mathbb{Z} : k \leq x \} \). Then \( x \) is an upper bound for \( S \) and so \( S \) has a least upper bound \( b \). Consequently, \( k \leq b \) for all \( k \in S \). Since \( b - 1 \) is not an upper bound for \( S \), it follows that there is an integer \( m \in S \) for which \( b - 1 < m \). Let \( n = m + 1 \). Then \( n \in \mathbb{N} \) and \( n > b \). Since \( n \notin S \), it follows that \( n > x \). ■

We now present two consequences of the Archimedean Principle.

**Corollary 18.8** For every two real numbers \( x \) and \( y \) with \( x > 0 \), there exists a positive integer \( n \) such that \( nx > y \).

**Proof** Consider the real number \( y/x \). By Theorem 18.7, there exists a positive integer \( n \) such that \( n > y/x \). Thus, \( nx > y \). ■

**Corollary 18.9** For every positive real number \( \epsilon \), there exists a positive integer \( n \) such that \( 1/n < \epsilon \).

**Proof** By Corollary 18.8, there exists a positive integer \( n \) such that \( ne > 1 \). Thus, \( 1/n < \epsilon \). ■

We are now in a position to establish two important properties of real numbers, namely that both the rational numbers and the irrational numbers are **dense** in the real numbers; that is, for every two real numbers \( a \) and \( b \) with \( a < b \), there is a rational number \( r \) and an irrational number \( t \) such that \( a < r < b \) and \( a < t < b \). If \( a \) and \( b \) are rational numbers with \( a < b \), then \( \frac{a+b}{2} \) is rational and \( a < \frac{a+b}{2} < b \). Also, if \( a \) and \( b \) are both rational with \( a < b \), then so is \( b - a \), while \( a + \frac{b-a}{\sqrt{2}n} \) is irrational for every positive integer \( n \). Since \( \frac{b-a}{\sqrt{2}n} < b - a \), it follows that \( a < a + \frac{b-a}{\sqrt{2}n} < b \). More generally, we have the following two theorems.

**Theorem 18.10** (The Rational Numbers are Dense in \( \mathbb{R} \)) For every two real numbers \( a \) and \( b \) with \( a < b \), there exists a rational number \( r \) such that \( a < r < b \).

**Proof** First, if \( a < 0 \) and \( b > 0 \), then \( r = 0 \) has the desired property. If \( a = 0 \), then there is a positive integer \( n \) such that \( 1/n < b \) (by Corollary 18.9) and \( r = 1/n \) has the desired property. If \( b = 0 \), then \( -a > 0 \) and there is a positive integer \( n \) such that \( 1/n < -a \) and \( r = -1/n \).
has the desired property. Hence, we may assume that $a$ and $b$ are both positive or both negative. We consider these two cases.

**Case 1.** $0 < a < b$. By Corollary 18.9, then there is a positive integer $n$ such that $\frac{1}{n} < b - a$. Hence, $a < b - \frac{1}{n}$. For such a positive integer $n$, there exists a positive integer $m$ such that $\frac{1}{m} < \frac{1}{n}$ (again by Corollary 18.9). Thus, $m > nb$. Therefore, there are positive integers $m$ such that $m \geq nb$. By the Well-Ordering Principle (see Section 6.1), the set $S = \{m \in \mathbb{N} : m \geq nb \}$ has a least element $m_0$. Therefore, $m_0 \in S$ but $m_0 - 1 \notin S$ and so $m_0 \geq nb$ while $m_0 - 1 < nb$. Therefore, $\frac{m_0 - 1}{n} < b$. However, $m_0 \geq nb$, so $b \leq \frac{m_0}{n}$. Thus, $a < b - \frac{1}{n} \leq \frac{m_0}{n} - \frac{1}{n} = \frac{m_0 - 1}{n} < b$.

Letting $r = \frac{m_0 - 1}{n}$, we have $a < r < b$.

**Case 2.** $a < b < 0$. Thus, $0 < -b < -a$. By Case 1, there is a rational number $r$ such that $-b < r < -a$ and so the rational number $-r$ satisfies $a < -r < b$.

**Theorem 18.11** (The Irrational Numbers are Dense in $\mathbb{R}$) For every two real numbers $a$ and $b$ with $a < b$, there exists an irrational number $t$ such that $a < t < b$.

**Proof** If $0 \leq a < b$ or $a < b \leq 0$, then by Theorem 18.10, there is a nonzero rational number $r$ such that $\frac{a}{\sqrt{2}} < r < \frac{b}{\sqrt{2}}$. If $a < 0$ and $b > 0$, then there is a rational number $r$ such that $0 < r < \frac{b}{\sqrt{2}}$. In either case, $a < \sqrt{2} r < b$. Since $\sqrt{2} r$ is an irrational number, $t = \sqrt{2} r$ has the desired property.

### 18.3 Open and Closed Sets of Real Numbers

For a real number $x$ and a positive real number $\varepsilon$, the $\varepsilon$-neighborhood $N_\varepsilon(x)$ of $x$ is the open interval

$$N_\varepsilon(x) = \{ y \in \mathbb{R} : |y - x| < \varepsilon \} = (x - \varepsilon, x + \varepsilon).$$

By the deleted $\varepsilon$-neighborhood $N^*_\varepsilon(x)$ of $x$ is meant the set

$$N^*_\varepsilon(x) = \{ y \in \mathbb{R} : 0 < |y - x| < \varepsilon \} = (x - \varepsilon, x) \cup (x, x + \varepsilon).$$

That is, $N^*_\varepsilon(x) = N_\varepsilon(x) - \{x\}$. A neighborhood of a real number $x$ is an $\varepsilon$-neighborhood of $x$ for some $\varepsilon > 0$, while a deleted neighborhood of $x$ is a deleted $\varepsilon$-neighborhood of $x$ for some $\varepsilon > 0$. Therefore, a neighborhood of $x$ is an open interval centered at $x$. A neighborhood of $x$ is often denoted by $N(x)$, or more simply by $N$, and a deleted neighborhood of $x$ is commonly denoted by $N^*(x)$.

A point $x$ belonging to a set $S$ of real numbers is an **interior point** of $S$ if there exists some neighborhood $N$ of $x$ for which $N \subseteq S$. In particular, every point of a neighborhood or deleted neighborhood of any real number is an interior point. The set of all interior points of $S$ is called the **interior** of $S$ and is denoted by $\text{Int}(S)$.
Chapter 18  Proofs with Real and Complex Numbers

Example 18.12  Determine the interior of each of the following sets of real numbers.

\( (a) \ S = (0, 1) \quad (b) \ S = [-1, 0) \cup (0, 1] \quad (c) \ S = \{ x \in \mathbb{R} : x \geq 0 \} \)

\( (d) \ S = \mathbb{R} \quad (e) \ S = \left\{ \frac{1}{n} : n \in \mathbb{N} \right\} \quad (f) \ S = \bigcap_{n \in \mathbb{N}} \left[-\frac{1}{n}, \frac{1}{n}\right] \)

\( (g) \ S = \emptyset. \)

**Solution**

\( (a) \ \text{Int}(S) = (0, 1) = N_1 \left( \frac{1}{2} \right) \quad (b) \ \text{Int}(S) = (-1, 0) \cup (0, 1) = N_1^*(0) \)

\( (c) \ \text{Int}(S) = \mathbb{R}^+ \quad (d) \ \text{Int}(S) = \mathbb{R} \quad (e) \ \text{Int}(S) = \emptyset \)

\( (f) \ \text{Int}(S) = \emptyset \quad (g) \ \text{Int}(S) = \emptyset. \)

A set \( S \) of real numbers is called an **open set** if every point of \( S \) is an interior point of \( S \). Hence, \( \text{Int}(S) = S \) if and only if \( S \) is an open set. Thus, every open interval of real numbers is an open set. Furthermore, since \( \text{Int}(\mathbb{R}) = \mathbb{R} \) and \( \text{Int}(\emptyset) = \emptyset \) (as seen above), both \( \mathbb{R} \) and \( \emptyset \) are open sets. Not only is \( \text{Int}(S) \) an open set for all those sets \( S \) mentioned in Example 18.12, the interior of every set is an open set (see Exercise 18.22). Since \( \text{Int}(S) \) is always a subset of \( S \), it suffices to show that \( S \subseteq \text{Int}(S) \) when establishing that a set \( S \) is open. That is, to show that a set \( S \) is open, it suffices to show that every point of \( S \) is an interior point of \( S \).

A set \( S \) of real numbers is called a **closed set** if its complement \( S^c \) is open. Consequently, every closed interval of real numbers is a closed set, as are both \( \mathbb{R} \) and \( \emptyset \).

Example 18.13  Determine which of the following sets of real numbers are open, which are closed and which are neither.

\( (a) \ S = [0, \infty) \quad (b) \ S = (0, \infty) \quad (c) \ S = [0, 1] \cup [2, 3) \)

\( (d) \ S = \{1, 2, 3\} \quad (e) \ S = \left\{ \frac{1}{n} : n \in \mathbb{N} \right\} \quad (f) \ S = \bigcap_{n \in \mathbb{N}} (n, n + \frac{1}{n}). \)

**Solution**

First, the set \( S \) in (b) is open. Since the set \( S \) in (f) is \( \emptyset \), this set is both open and closed. The sets \( S \) in (a) and (d) are both closed. The sets \( S \) in (c) and (e) are neither.

For a set \( S \) of real numbers, a point \( x \in \mathbb{R} \) is called a **boundary point** of \( S \) if every neighborhood \( N \) of \( x \) contains both a point in \( S \) and a point not in \( S \), that is, \( \mathbb{N} \cap S \neq \emptyset \) and \( N \cap \overline{S} \neq \emptyset \). The set of all boundary points of \( S \) is called the **boundary** of \( S \) and is denoted by \( \text{Bd}(S) \). Therefore, for every set \( S \) of real numbers, \( \text{Bd}(S) = \overline{\text{Bd}(S)} \).

Example 18.14  Determine the boundary of each of the following sets of real numbers.

\( (a) \ S = (0, 1) \quad (b) \ S = [-1, 0) \cup (0, 1] \quad (c) \ S = \{ x \in \mathbb{R} : x \geq 0 \} \)

\( (d) \ S = \mathbb{R} \quad (e) \ S = \left\{ \frac{1}{n} : n \in \mathbb{N} \right\} \quad (f) \ S = \bigcap_{n \in \mathbb{N}} \left[-\frac{1}{n}, \frac{1}{n}\right]. \)

**Solution**

\( (a) \ \text{Bd}(S) = [0, 1] \quad (b) \ \text{Bd}(S) = \{-1, 0, 1\} \quad (c) \ \text{Bd}(S) = \{0\} \)

\( (d) \ \text{Bd}(S) = \emptyset \quad (e) \ \text{Bd}(S) = S \cup \{0\} \quad (f) \ \text{Bd}(S) = \{0\}. \)
The following theorem gives a characterization of sets $S$ of real numbers that are closed in terms of the boundary of $S$.

**Theorem 18.15** A set $S$ of real numbers is closed if and only if $\text{Bd}(S) \subseteq S$.

**Proof**

First, suppose that $S$ is a closed set. Then $\overline{S}$ is an open set. Assume, to the contrary, that $\text{Bd}(S) \not\subseteq S$. Then there exists some real number $x \in \text{Bd}(S)$ such that $x \notin S$. Since $\overline{S}$ is an open set, there is a neighborhood $N$ of $x$ such that $N \subseteq \overline{S}$, contradicting the fact that $x$ is a boundary point of $S$.

For the converse, assume that $S$ is a set such that $\text{Bd}(S) \subseteq S$. We show that $S$ is a closed set or, equivalently, that $\overline{S}$ is an open set. Let $x \in \overline{S}$. Thus, $x \notin S$. Since $\text{Bd}(S) \subseteq S$, it follows that $x \notin \text{Bd}(S)$. Hence, there is a neighborhood $N$ of $x$ such that $N \cap S = \emptyset$. Therefore, $N \subseteq \overline{S}$ and so $\overline{S}$ is open.

Some open sets can be constructed from certain collections of open sets.

**Theorem 18.16**

(a) The union of any collection of open sets of real numbers is an open set.

(b) The intersection of any finite collection of open sets of real numbers is an open set.

**Proof**

(a) Let $\{S_\alpha\}_{\alpha \in I}$ be a collection of open sets of real numbers (where $I$ is an index set) and let $x \in \bigcup_{\alpha \in I} S_\alpha$. Then $x \in S_\alpha$ for some $\alpha \in I$. Since $S_\alpha$ is an open set, there is a neighborhood $N$ of $x$ such that $N \subseteq S_\alpha$. Consequently, $N \subseteq \bigcup_{\alpha \in I} S_\alpha$ and so $\bigcup_{\alpha \in I} S_\alpha$ is open.

(b) Let $\{S_1, S_2, \ldots, S_n\}$ be a (finite) collection of open sets of real numbers and let $x \in \bigcap_{i=1}^n S_i$. Thus, $x \in S_i$ for each $i$ with $1 \leq i \leq n$. Since $S_i$ is an open set for $1 \leq i \leq n$, there is an $\epsilon_i$-neighborhood $N_i$ of $x$, where $\epsilon_i > 0$, such that $N_i \subseteq S_i$. Let $\epsilon = \min\{\epsilon_i : 1 \leq i \leq n\}$ and let $N = N_\epsilon(x)$. Since $N \subseteq N_i$ for $i = 1, 2, \ldots, n$, it follows that $N \subseteq S_i$ for $i = 1, 2, \ldots, n$. Therefore, $N \subseteq \bigcap_{i=1}^n S_i$ and so $\bigcap_{i=1}^n S_i$ is open.

**Example 18.17** For each positive integer $n$, the open interval $(-\frac{1}{n}, \frac{1}{n})$ is an open set. Since $\bigcap_{n \in \mathbb{N}} S_n = \{0\}$ is not an open set, it follows that Theorem 18.16(b) cannot be extended to say that the intersection of any collection of open sets of real numbers is open.

In Theorem 6.15, we saw (by one of De Morgan’s laws) that for any finite number $A_1, A_2, \ldots, A_n$ of sets,

$$\bigcup_{i=1}^n A_i = \bigcap_{i=1}^n A_i.$$
Chapter 18  Proofs with Real and Complex Numbers

By Exercise 6.29, the following is also true:

\[
\bigcap_{i=1}^{n} A_i = \bigcup_{i=1}^{n} A_i.
\]

In fact, there is a De Morgan’s law in both cases for any collection \( \{S_\alpha\}_{\alpha \in I} \) of sets being considered. From this result and Theorem 18.16, we have the following.

**Corollary 18.18**

(a) The intersection of any collection of closed sets of real numbers is a closed set.

(b) The union of any finite collection of closed sets of real numbers is a closed set.

Let \( S \) be a set of real numbers. A real number \( x \) is an **accumulation point** of \( S \) if every deleted neighborhood of \( x \) contains a point of \( S \). The set of accumulation points of \( S \) is denoted by \( \text{Acc}(S) \). Thus, every interior point of \( S \) is an accumulation point of \( S \) and so \( \text{Int}(S) \subseteq \text{Acc}(S) \).

A real number \( x \in S \) is called an **isolated point** of \( S \) if there exists some deleted neighborhood of \( x \) containing no point of \( S \). Therefore, a point \( x \in S \) is an isolated point of \( S \) if and only if \( x \) is not an accumulation point of \( S \).

The **closure** of a set \( S \) of real numbers is the set \( \text{Cl}(S) = S \cup \text{Acc}(S) \).

**Theorem 18.19**  Let \( S \) be a set of real numbers. Then a real number \( x \) belongs to \( \text{Cl}(S) \) if and only if every neighborhood of \( x \) contains an element of \( S \).

**Proof**  Let \( x \in \text{Cl}(S) \). Then \( x \in S \) or \( x \) is an accumulation point of \( S \). In either case, every neighborhood of \( x \) contains an element of \( S \).

For the converse, suppose that \( x \) is a real number having the property that every neighborhood of \( x \) contains an element of \( S \). If \( x \notin S \), then every deleted neighborhood of \( x \) contains an element of \( S \). Thus, either \( x \in S \) or \( x \) is an accumulation point of \( S \) and so \( x \in \text{Cl}(S) \).

While Theorem 18.15 states that a set \( S \) of real numbers is closed if and only if \( \text{Bd}(S) \subseteq S \), the same can be said if \( \text{Bd}(S) \) is replaced by \( \text{Acc}(S) \).

**Theorem 18.20**  A set \( S \) of real numbers is closed if and only if \( \text{Acc}(S) \subseteq S \).

**Proof**  First, let \( S \) be a closed set and assume, to the contrary, that there is an accumulation point \( x \) of \( S \) that does not belong to \( S \). Therefore, \( x \notin \bar{S} \). Since \( S \) is closed, \( \bar{S} \) is open. Consequently, there is a neighborhood \( N \) of \( x \) such that \( N \subseteq \bar{S} \). However then, \( N \cap S = \emptyset \), which contradicts the fact that \( x \) is an accumulation point of \( S \).

We now verify the converse. Assume that \( \text{Acc}(S) \subseteq S \). We show that \( S \) is a closed set or, equivalently, that \( \bar{S} \) is an open set. Let \( x \in \bar{S} \). Since \( \text{Acc}(S) \subseteq S \), it follows that \( x \) is not an accumulation point of \( S \). Consequently, there is a neighborhood \( N \) of \( x \) such that \( N \cap S = \emptyset \) and so \( N \subseteq \bar{S} \). Hence, \( \bar{S} \) is open.

Employing the concept of accumulation point, we can show that all nonempty closed sets of real numbers which are bounded have an interesting property.
18.3 Open and Closed Sets of Real Numbers

**Theorem 18.21** Every nonempty, closed, bounded set of real numbers has both a maximum element and a minimum element.

**Proof** Let \( S \) be a nonempty, closed, bounded set of real numbers. Since \( S \) has an upper bound, \( \text{sup}(S) \) exists, say \( \text{sup}(S) = b \). We claim that \( b \in S \).

Suppose that \( b \not\in S \). Then for a positive integer \( \epsilon \), there exists \( y \in S \) such that \( b - \epsilon < y < b \), so \( N^*(b) \cap S \neq \emptyset \). Hence, \( b \in \text{Acc}(S) \). Since \( S \) is closed, it follows by Theorem 18.20 that \( b \in S \), which is a contradiction. Consequently, \( \text{max}(S) \) exists and \( \text{max}(S) = b \). Similarly, \( S \) contains a minimum element.

**Example 18.22** Determine the set of accumulation points and the closure of each of the following sets of real numbers as well as identify any isolated points in the set.

\((a)\) \( S = \{ \frac{1}{n} : n \in \mathbb{N} \} \) \hspace{1cm} \((b)\) \( S = \bigcap_{n \in \mathbb{N}} \left( -\frac{1}{n}, \frac{1}{n} \right) \)

\((c)\) \( S = (1, 2] \) \hspace{1cm} \((d)\) \( S = \mathbb{Q} \cap [0, 1] \)

\((e)\) \( S = \{1, 2, 3\} \) \hspace{1cm} \((f)\) \( S = \mathbb{R} \)

**Solution**

\((a)\) \( \text{Acc}(S) = \{0\} \), \( \text{Cl}(S) = S \cup \{0\} \). All points of \( S \) are isolated points.

\((b)\) \( S = \{0\} \), \( \text{Acc}(S) = \emptyset \), \( \text{Cl}(S) = \{0\} \). The point 0 is an isolated point.

\((c)\) \( \text{Cl}(S) = \text{Acc}(S) = [1, 2] \).

\((d)\) \( \text{Cl}(S) = \text{Acc}(S) = [0, 1] \).

\((e)\) \( \text{Acc}(S) = \emptyset \), \( \text{Cl}(S) = S \). Each point of \( S \) is an isolated point.

\((f)\) \( \text{Cl}(S) = \text{Acc}(S) = \mathbb{R} \).

Not surprisingly, the closure of every set of real numbers is a closed set.

**Theorem 18.23** If \( S \) is a set of real numbers, then \( \text{Cl}(S) \) is a closed set.

**Proof** By Theorem 18.20, it suffices to show that \( \text{Acc}(\text{Cl}(S)) \subseteq \text{Cl}(S) \). Let \( x \in \text{Acc}(\text{Cl}(S)) \).

Thus, \( x \) is an accumulation point of \( \text{Cl}(S) \). Let \( N = N(x) \) be a neighborhood of \( x \). Thus, \( N \) contains a point \( y \in \text{Cl}(S) \) that is distinct from \( x \). Since \( y \in \text{Cl}(S) = S \cup \text{Acc}(S) \), it follows that \( y \in S \) or \( y \in \text{Acc}(S) \).

First, suppose that \( y \in S \). Then \( N^*(x) \cap S \neq \emptyset \). Next, suppose that \( y \in \text{Acc}(S) \). Since \( N^*(x) \) is an open set, there is a neighborhood \( N'(y) \) such that \( N'(y) \subseteq N^*(x) \). Since \( y \in \text{Acc}(S) \), there is a point \( z \in S \cap N'(y) \) such that \( z \) is different from both \( y \) and \( x \).

Consequently, each deleted neighborhood of \( x \) contains a point of \( S \), which implies that \( x \in \text{Acc}(S) \) and so \( x \in \text{Cl}(S) \).

**Theorem 18.24** Let \( S \) be a set of real numbers. Then \( \text{Cl}(S) = S \) if and only if \( S \) is a closed set.

**Proof** First, suppose that \( \text{Cl}(S) = S \). Then \( S \) is a closed set by Theorem 18.23. For the converse, suppose that \( S \) is a closed set. By Theorem 18.20, \( \text{Acc}(S) \subseteq S \). Then \( \text{Cl}(S) = S \cup \text{Acc}(S) = S \).
Chapter 18  Proofs with Real and Complex Numbers

18.4 COMPACT SETS OF REAL NUMBERS

A collection \( \{S_a\}_{a \in I} \) of sets of real numbers is called a **cover** of a set \( S \) of real numbers if \( S \subseteq \bigcup_{a \in I} S_a \). If every set \( S_a, \ a \in I \), is an open set, then \( \{S_a\}_{a \in I} \) is called an **open cover** of \( S \). If \( \{S_a\}_{a \in I} \) is a cover (or open cover) of \( S \) and \( J \subseteq I \) such that \( \{S_a\}_{a \in J} \) is also a cover of \( S \), then \( \{S_a\}_{a \in J} \) is called a **subcover** (or **open subcover**) of \( S \).

**Example 18.25**

(a) Let \( S = \mathbb{Z} \) and let \( S_n = (n - 1, n + 1) \) for each \( n \in \mathbb{Z} \). Then \( \{S_n\}_{n \in \mathbb{Z}} \) is an open cover of \( S \).

(b) Let \( S = [2, 3] \) and let \( S_\alpha = (\alpha - \frac{1}{2}, \alpha + \frac{1}{2}) \) for each \( \alpha \in S \). Then \( \{S_\alpha\}_{\alpha \in S} \) is an open cover of \( S \).

(c) Let \( S = \left\{ \frac{1}{n} : n \in \mathbb{N} \right\} \) and let \( I = \mathbb{N} \cup \{0\} \). Furthermore, let \( S_0 = (-1, 1) \), \( S_1 = \left( \frac{1}{2}, 2 \right) \) and \( S_n = (-1, \frac{1}{n}) \) for each \( n \in \mathbb{N} \setminus \{1\} \). Then \( \{S_\alpha\}_{\alpha \in I} \) is an open cover of \( S \). For \( J = \{0, 1\}, \{S_\alpha\}_{\alpha \in J} = \{S_0, S_1\} \) is an open subcover of \( S \).

A set \( S \) of real numbers is called **compact** if every open cover of \( S \) contains a finite subcover. That is, \( S \) is compact if for every open cover \( \{S_\alpha\}_{\alpha \in I} \) of \( S \), there is a finite subset \( J \) of \( I \) such that \( \{S_\alpha\}_{\alpha \in J} \) is also a cover of \( S \).

A major theorem concerning properties of real numbers is the Heine–Borel Theorem, which characterizes compact sets of real numbers as those sets that are closed and bounded. This theorem was initially proved and used by the mathematician Peter Gustav Lejeune Dirichlet in the 1860s, although only published in 1904. Similar techniques were later used by Eduard Heine, Karl Weierstrass and Salvatore Pincherle. The first mathematician to state and prove the theorem in the form usually presented was Émile Borel, which occurred in 1895. First, we state and prove a lemma that turns out to be a special case of the Heine–Borel Theorem.

**Lemma 18.26**

Let \( S = [a, b] \) be a closed interval, where \( a, b \in \mathbb{R} \) and \( a \leq b \). Then every open cover of \( S \) has a finite open subcover.

**Proof**

Let \( \{S_\alpha\}_{\alpha \in I} \) be an open cover of \( S \). Certainly, \( \{a\} \) is covered by one of these open sets. Let \( X = \{x \in [a, b] : \{a, x\} \text{ has a finite subcover}\} \).

Since \( a \in X \), it follows that \( X \neq \emptyset \). Furthermore, because \( b \) is an upper bound for \( X \), the set \( X \) has a least upper bound \( c \). Since \( c \in [a, b] \), there exists \( \beta \in I \) such that \( c \in S_\beta \). Since \( S_\beta \) is an open set, there exists an \( \varepsilon \)-neighborhood \( N_\varepsilon(c) \) of \( c \) such that \( N_\varepsilon(c) \subseteq S_\beta \), that is, \( (c - \varepsilon, c + \varepsilon) \subseteq S_\beta \). Because \( c - \varepsilon \) is not an upper bound for \( X \), there is \( x \in X \) for which \( x > c - \varepsilon \). There is a finite open subcover of \( [a, x] \), which we denote by \( \{S_1, S_2, \ldots, S_n\} \). Then \( \{S_1, S_2, \ldots, S_n, S_\beta\} \) is a finite subcover of \( [a, c + \varepsilon] \). If \( b \in [a, c + \varepsilon] \), then \( c = b \), completing the proof. Otherwise, \( b \notin [a, c + \varepsilon] \) and so \( c + \frac{\varepsilon}{2} \in X \), contradicting the fact that \( c \) is an upper bound for \( X \).

By Lemma 18.26, every closed interval is a compact set. Of course, every closed interval is a closed and bounded set. The Heine–Borel Theorem states that sets possessing these two properties are the only sets that are compact.
Theorem 18.27 (The Heine–Borel Theorem) A set $S$ of real numbers is compact if and only if $S$ is closed and bounded.

**Proof**

First, assume that $S$ is a compact set of real numbers. We begin by showing that $S$ is bounded. Let $T_n = (-n, n)$ for each $n \in \mathbb{N}$. Since $\bigcup_{n \in \mathbb{N}} T_n = \mathbb{R}$, it follows that $S \subseteq \bigcup_{n \in \mathbb{N}} T_n$ and so $\{T_n\}_{n \in \mathbb{N}}$ is an open cover of $S$. Because $S$ is compact, this open cover has a finite subcover, say $\{T_n\}_{n \in J}$ where $J$ is a finite subset of $\mathbb{N}$. Let $M$ be the largest integer in $J$. Then

$$\bigcup_{n \in J} T_n = T_M = (-M, M)$$

and so $M$ is an upper bound and $-M$ a lower bound for $S$. That is, $S$ is bounded.

Next, we show that $S$ is closed. By Theorem 18.20, it suffices to show that every accumulation point of $S$ belongs to $S$. Assume, to the contrary, that there is an accumulation point $x$ of $S$ that does not belong to $S$. That is, $x \notin S$. For each $n \in \mathbb{N}$, let $S_n = \left[ x - \frac{1}{n}, x + \frac{1}{n} \right] = (-\infty, x - \frac{1}{n}) \cup \left( x, x + \frac{1}{n}, \infty \right)$. Thus, each set $S_n$ is open. Since $x \notin S$, it follows that $S \subseteq \bigcup_{n \in \mathbb{N}} S_n$ and so $\{S_n\}_{n \in \mathbb{N}}$ is an open cover of $S$. Because $S$ is compact, this open cover has a finite subcover, say $\{S_n\}_{n \in J}$ where $J$ is a finite subset of $\mathbb{N}$. Let $M$ be the largest integer in $J$. Then

$$S \subseteq \left( -\infty, x - \frac{1}{M} \right) \cup \left( x + \frac{1}{M}, \infty \right).$$

However then, $\left[ x - \frac{1}{M}, x + \frac{1}{M} \right]$ contains no point of $S$ and so $\left( x - \frac{1}{M}, x + \frac{1}{M} \right)$ also contains no point of $S$, contradicting the fact that $x$ is an accumulation point of $S$.

We now verify the converse. Let $S$ be a set of real numbers that is closed and bounded. We show that $S$ is compact. Let $\{S_a\}_{a \in I}$ be an open cover of $S$. Since $S$ is a bounded set, there is a closed interval $[a, b]$ such that $S \subseteq [a, b]$. Because $S$ is closed, $\overline{S}$ is open. Then $\overline{S} \cup \{S_a\}_{a \in I}$ is a collection of open sets. Since $S \subseteq \bigcup_{a \in I} S_a$, it follows that

$$\left( \bigcup_{a \in I} S_a \right) \cup \overline{S} = \mathbb{R}.$$ 

Thus, $\overline{S} \cup \{S_a\}_{a \in I}$ is an open cover of $\mathbb{R}$ and of $[a, b]$ as well. By Lemma 18.26, there is a finite subcover of $[a, b]$ and hence, of $S$ as well. We consider two cases.

**Case 1.** *The finite subcover does not contain $\overline{S}$.* Then this is a finite subcollection of $\{S_a\}_{a \in I}$ that is an open cover of $S$.

**Case 2.** *The finite subcover contains $\overline{S}$.* Suppose that the subcover is $\{S_1, S_2, \ldots, S_n, \overline{S}\}$. Since $S$ and $\overline{S}$ are disjoint, $S \subseteq \bigcup_{i=1}^n S_i$ and so $\{S_1, S_2, \ldots, S_n\}$ is an open cover of $S$.$\blacksquare$

The Heine–Borel Theorem implies that every compact set of real numbers possesses an interesting and useful property.
Corollary 18.28 Every nonempty compact set of real numbers contains both a maximum and minimum element.

Proof Let $S$ be a nonempty compact set of real numbers. By Theorem 18.21, the set $S$ is closed and bounded and so by Theorem 18.21, $S$ contains both a maximum and minimum element.

A theorem closely related to the Heine–Borel Theorem is the Bolzano–Weierstrass Theorem. This theorem is named for the two mathematicians Bernard Bolzano and Karl Weierstrass, but was first proved by Bolzano in 1817 as a lemma used in proving the Intermediate Value Theorem of Calculus. Some 50 years later, this theorem was recognized as important in itself and proved again – this time by Weierstrass.

Theorem 18.29 (The Bolzano–Weierstrass Theorem) Every bounded infinite set of real numbers has at least one accumulation point.

Proof Assume, to the contrary, that there is a bounded infinite set $S$ of real numbers that has no accumulation points. Since $\text{Acc}(S) = \emptyset$, it follows by Theorem 18.20 that $S$ is a closed set. Because $S$ is closed and bounded, it follows by the Heine–Borel Theorem that $S$ is compact. Since $\text{Acc}(S) = \emptyset$, it follows that for each $x \in S$, there is a neighborhood $N_x$ of $x$ such that $N_x \cap S = \{x\}$. Then $\{N_x\}_{x \in S}$ is an open cover of $S$. Since $S$ is compact, there is a finite subcover $\{N_{x_1}, N_{x_2}, \ldots, N_{x_n}\}$. However, since

$$S \cap \left( \bigcup_{i=1}^{n} N_{x_i} \right) = \{x_1, x_2, \ldots, x_n\},$$

it follows that $S$ is finite, a contradiction.

18.5 COMPLEX NUMBERS

A linear equation with integer coefficients is an equation of the type $ax + b = 0$ where $a, b \in \mathbb{Z}$ and $a \neq 0$. Many such equations do not have integer roots. For example, $2x + 1 = 0$ has no integer roots. In fact, it is equations such as these that suggest the necessity of introducing rational numbers so that equations $ax + b = 0$, where $a, b \in \mathbb{Z}$ and $a \neq 0$, always have a rational root, namely $x = -b/a \in \mathbb{Q}$. Indeed, if $ax + b = 0$ where $a, b \in \mathbb{Q}$ and $a \neq 0$, then this equation has the rational root $-b/a$. Furthermore, if $a, b \in \mathbb{R}$ and $a \neq 0$, then $ax + b = 0$ has the real number root $x = -b/a$. Consequently, linear equations with real coefficients always have a real root, while linear equations with rational coefficients always have a rational root. As we saw, linear equations with integer coefficients do not in general have an integer root.

In the case of quadratic equations $ax^2 + bx + c = 0$ with $a, b, c \in \mathbb{R}$ and $a \neq 0$, the situation is quite different. There is no guarantee of real number roots for such an equation. For example, the equation $x^2 + 1 = 0$, or equivalently $x^2 = -1$, has no real number root since the square of every real number is a nonnegative real number. This suggests extending the set $\mathbb{R}$ of real numbers to include a new number $i$ for which $i^2 = -1$, that is, $i = \sqrt{-1}$. The equation $x^2 = -1$ then has two roots, namely $i$ and $-i$. This brings us to another important class of numbers.
A **complex number** \( z \) is a number of the form \( a + bi \), where \( a, b \in \mathbb{R} \) and \( i = \sqrt{-1} \). While complex numbers can be represented in other ways, \( a + bi \) is the most common way of representing a complex number \( z \) and is referred to as the **rectangular representation** or **rectangular form** of \( z \). Recall that \( \mathbb{C} \) denotes the set of complex numbers.

While \( \sqrt{a/b} = \sqrt{ab} \) for every two nonnegative real numbers \( a \) and \( b \), such is not the case for negative real numbers. For example, \( \sqrt{-1} \sqrt{-1} = (\sqrt{-1})^2 = i^2 = -1 \) but \( \sqrt{(-1)(-1)} = \sqrt{1} = 1 \). Thus, \( \sqrt{-1} \sqrt{-1} \neq \sqrt{(-1)(-1)} \).

For the complex number \( z = a + bi \), the real number \( a \) is called the **real part** of \( z \) and denoted by \( \text{Re}(z) \) and \( b \) is called the **imaginary part** of \( z \) and denoted by \( \text{Im}(z) \). Thus, if \( z = 3 + (-1)i = 3 - i \), then the real part of \( z \) is 3 and its imaginary part is -1.

Two complex numbers \( z_1 \) and \( z_2 \) are **equal** if \( \text{Re}(z_1) = \text{Re}(z_2) \) and \( \text{Im}(z_1) = \text{Im}(z_2) \); that is, \( a + bi = c + di \), where \( a, b, c, d \in \mathbb{R} \), if \( a = c \) and \( b = d \). If the imaginary part of a complex number \( z \) is 0, then \( z \) is a real number and so \( \mathbb{R} \subseteq \mathbb{C} \). According to the quadratic formula, the roots of the quadratic equation \( az^2 + bz + c = 0 \), where \( a, b, c \in \mathbb{R} \) and \( a \neq 0 \), are

\[
z = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.
\]

that is, there are two roots, namely

\[
\frac{-b + \sqrt{b^2 - 4ac}}{2a} \quad \text{and} \quad \frac{-b - \sqrt{b^2 - 4ac}}{2a}.
\]

The real number \( b^2 - 4ac \) is referred to as the **discriminant** of the quadratic polynomial \( p(z) = az^2 + bz + c \). The roots of \( p(z) \) are real numbers if the discriminant \( b^2 - 4ac \geq 0 \) and the roots are equal if and only if \( b^2 - 4ac = 0 \). On the other hand, these roots are complex numbers that are not real if \( b^2 - 4ac < 0 \). Long ago, such equations were declared unsolvable. However, complex numbers allow us to solve every quadratic equation with the quadratic formula. Not only does every quadratic equation with real coefficients have two (not necessarily distinct) complex number roots, but it turns out that every quadratic equation with complex coefficients has two complex number roots as well. While we’ll discuss this in more detail soon, let’s look at an example.

**Example 18.30** Determine the roots of the quadratic equation \( 5z^2 + 6z + 5 = 0 \).

**Solution** Applying the quadratic formula to this equation (with \( a = 5 \) and \( b = 6 \)), we have

\[
z = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} = \frac{-6 \pm \sqrt{36 - 100}}{10} = \frac{-6 \pm \sqrt{-64}}{10} = \frac{-3 \pm 4i}{5},
\]

Not only are complex numbers the roots of this and every quadratic equation but a classic theorem in mathematics tells us that something much more general is true. This theorem provides one of many reasons as to why complex numbers are so important in the study of mathematics.

**The Fundamental Theorem of Algebra** Every polynomial equation

\[a_nz^n + a_{n-1}z^{n-1} + \cdots + a_1z + a_0 = 0\]
16 Chapter 18 Proofs with Real and Complex Numbers

where \( n \geq 1 \), \( a_i \in \mathbb{C} \) for \( 0 \leq i \leq n \) and \( a_n \neq 0 \) has \( n \) (not necessarily distinct) roots, all of which are complex numbers.

As is the case with integers, rational numbers and real numbers, it is possible to add, subtract, multiply and divide two complex numbers, provided we are not dividing by the zero complex number \( 0 = 0 + 0i \).

For two complex numbers \( z_1 = a + bi \) and \( z_2 = c + di \), where \( a, b, c, d \in \mathbb{R} \), the sum \( z_1 + z_2 \) and product \( z_1z_2 \) of \( z_1 \) and \( z_2 \) are defined by

\[
z_1 + z_2 = (a + bi) + (c + di) = (a + c) + (b + d)i
\]

\[
z_1z_2 = (a + bi)(c + di) = (ac - bd) + (ad + bc)i.
\]

The difference \( z_1 - z_2 \) of \( z_1 \) and \( z_2 \) is then

\[
z_1 - z_2 = (a + bi) - (c + di) = (a - c) + (b - d)i.
\]

The conjugate of the complex number \( z_1 = a + bi \) is the complex number

\[
\overline{z_1} = a - bi = a + (-b)i.
\]

Consequently,

\[
\overline{z_1} = z_1, \overline{z_1 + z_2} = \overline{z_1} + \overline{z_2}, \overline{z_1z_2} = \overline{z_1} \cdot \overline{z_2} \text{ and } z_1\overline{z_1} = (a + bi)(a - bi) = a^2 + b^2.
\]

The quotient \( z_1/z_2 \), where \( z_2 \neq 0 \) (that is, \( c \neq 0 \) or \( d \neq 0 \)), can be written as

\[
\frac{z_1}{z_2} = \frac{a + bi}{c + di} = \frac{z_1}{z_2} \cdot \frac{z_2}{z_2} = \frac{a + bi}{c + di} \cdot \frac{c - di}{c - di} = \frac{(ac + bd) + (bc - ad)i}{c^2 + d^2} = \frac{ac + bd}{c^2 + d^2} + \frac{bc - ad}{c^2 + d^2}i.
\]

Hence, the sum, difference, product and quotient of two complex numbers (where the denominator is nonzero in the case of division) is once again a complex number. With these definitions of addition, subtraction, multiplication and division, together with the unity (multiplicative identity) \( 1 = 1 + 0i \) and zero element (additive identity) \( 0 = 0 + 0i \), the set \( \mathbb{C} \) of complex numbers forms a field (see Section 16.5). The complex numbers are not an ordered field, however. If this were the case, then either \( i > 0 \) or \( i < 0 \). If \( i > 0 \), then \( i^2 = (-i)^2 = -1 > 0 \), which is impossible. If \( i < 0 \) or equivalently, \( 0 > i \), then since \( 1 > 0 \), it follows that \( 0 \cdot 1 > i \cdot 0 \), or \( 0 > 0 \), which is also impossible.

The complex number \( z = a + bi \) is sometimes represented by the ordered pair \((a, b)\) of real numbers \( a \) and \( b \) and further represented as a point in the plane (referred to as the complex plane in this case). This observation was first made by the famous British mathematician Sir William Rowan Hamilton. The geometric representation of a complex number \( z = a + bi \) is shown in Figure 18.1, where in this example \( a \) and \( b \) are positive real numbers. The \( x \)-axis in the complex plane is referred to as the real axis and the \( y \)-axis in the complex plane is also referred to as the imaginary axis. The directed line segment from the origin \((0, 0)\) to the point \((a, b)\) results in the vector \( \vec{z} \).

The modulus of a complex number \( z = a + bi \), denoted by \(|z|\), is defined by

\[|z| = \sqrt{a^2 + b^2}.\]

(The plural of modulus is moduli.) Equivalently, the modulus of \( z \) is the distance between the points \((0, 0)\) and \((a, b)\) and is the length of the vector \( \vec{z} \). Some of the fundamental properties of the modulus of a complex number are listed below (see Exercise 18.85).
The geometric representation of a complex number $z = a + bi$ can be represented as a point $(a, b)$ in the complex plane, where $a$ is the projection along the real axis and $b$ is the projection along the imaginary axis.

**Figure 18.1** The geometric representation of a complex number

**Theorem 18.31** For complex numbers $z_1 = a + bi$ and $z_2 = c + di$, where $a, b, c, d \in \mathbb{R}$,

(a) $|z_1|^2 = z_1 \cdot \overline{z_1} = a^2 + b^2$.

(b) $|Re(z_1)| \leq |z_1|$ and $|Im(z_1)| \leq |z_1|$.

(c) $|z_1^2| = |z_1|^2$, $|z_1| = |z_1|$ and $|z_1| = |\overline{z_1}|$.

(d) $|z_1 z_2| = |z_1| |z_2|$ and for $z_2 \neq 0$, $\left| \frac{z_1}{z_2} \right| = \frac{|z_1|}{|z_2|}$.

Another well-known property involving the modulus of a complex number is presented next.

**Theorem 18.32** *(The Triangle Inequality)* For complex numbers $z_1$ and $z_2$,

$$|z_1 + z_2| \leq |z_1| + |z_2|.$$ 

**Proof** Observe that

$$|z_1 + z_2|^2 = (z_1 + z_2)(\overline{z_1 + z_2}) = (z_1 + z_2)(\overline{z_1} + \overline{z_2})$$

$$= z_1 \overline{z_1} + z_1 \overline{z_2} + z_2 \overline{z_1} + z_2 \overline{z_2} = |z_1|^2 + |z_2|^2 + |z_1| |z_2| + |z_2|^2$$

$$= |z_1|^2 + 2Re(z_1 \overline{z_2}) + |z_2|^2 \leq |z_1|^2 + 2|Re(z_1 \overline{z_2})| + |z_2|^2$$

$$\leq |z_1|^2 + 2|z_1| |z_2| + |z_2|^2 = |z_1|^2 + 2|z_1| |z_2| + |z_2|^2$$

$$= (|z_1| + |z_2|)^2,$$

producing the desired property. 

A point $P$ in the plane with rectangular coordinates $(x, y)$ can also be described in terms of polar coordinates. In this system, the origin is called the pole, denoted by $O$, and the positive $x$-axis is called the polar axis. Here, the polar coordinates of $P$ are $(r, \theta)$, where $r = \sqrt{x^2 + y^2}$ is the distance between $O$ and $P$, which is also the length of the vector $\overrightarrow{OP}$ from $O$ to $P$. The number $\theta$ is the angle (in radians) measured from the
18 Chapter 18 Proofs with Real and Complex Numbers

polar axis to the line $OP$. The angle $\theta$ is positive if it is measured counterclockwise and negative if it is measured clockwise. While $r$ is unique, there are infinitely many choices for $\theta$ and so the polar coordinates of $P$ are not unique either.

The rectangular coordinates $(x, y)$ and the polar coordinates $(r, \theta)$ of a point in the plane are related by the equations

$$x = r \cos \theta \quad \text{and} \quad y = r \sin \theta.$$ 

Therefore, a complex number $z = x + yi$ can also be expressed as $z = r \cos \theta + i(r \sin \theta)$ or

$$z = r(\cos \theta + i \sin \theta),$$

which is referred to as the polar representation or polar form of the complex number $z$. (See Figure 18.2.)

Figure 18.2 Determining the polar representation of a complex number

The angle $\theta$ in the polar representation of a complex number $z$ is called an argument of $z$. Consequently, any argument $\theta$ of $z$ must satisfy the equations $\cos \theta = x/r$ and $\sin \theta = y/r$. Since $\cos \theta$ and $\sin \theta$ are periodic of period $2\pi$, an argument is not unique. Indeed, if $\theta_0$ is an argument of a complex number $z$, so are $\theta_0 \pm 2\pi$ and $\theta_0 \pm 4\pi$, for example. Since $\tan \theta = y/x$, an argument for $z$ can be found if we know its rectangular form. However, since $\tan \theta$ has period $\pi$, we must be a bit careful in determining $\theta$ when using $\tan \theta = y/x$ only. In fact, the inverse tangent $\tan^{-1}(y/x)$ of $y/x$ produces a solution for $\theta$. Because $-\frac{\pi}{2} < \tan^{-1}(y/x) < \frac{\pi}{2}$, it follows that $\tan^{-1}(y/x)$ only gives a value of $\theta$ in the first or fourth quadrant regardless of the quadrant in which $P$ is located.

While $\arg(z)$ represents a set of numbers $\theta$ such that $x = r \cos \theta$ and $y = r \sin \theta$, an argument $\theta$ satisfying $-\pi < \theta \leq \pi$ is called the principal argument of $z$. The principal argument of $z$ is unique and is often denoted by $\text{Arg}(z)$. In particular,

1. if $x > 0$, then $\text{Arg}(z) = \tan^{-1}\left(\frac{y}{x}\right)$
2. if $x < 0$ and $y \geq 0$, then $\text{Arg}(z) = \tan^{-1}\left(\frac{y}{x}\right) + \pi$
3. if $x < 0$ and $y < 0$, then $\text{Arg}(z) = \tan^{-1}\left(\frac{y}{x}\right) - \pi$.

Example 18.33 Find a polar form of the complex number $z = -1 + i$.

Solution Since $x = -1$ and $y = 1$, it follows that $r = \sqrt{2}$. Therefore, $\cos \theta = x/r = -1/\sqrt{2}$ and $\sin \theta = y/r = 1/\sqrt{2}$, while $\tan \theta = y/x = -1$. Since $\theta$ is an angle in the second quadrant, all of the angles $3\pi/4, 3\pi/4 + 2\pi = 11\pi/4, -5\pi/4$ and $-5\pi/4 - 2\pi = -13\pi/4$
are arguments of \( z \), while \( 3\pi/4 \) is the principal argument of \( z \). Therefore, the point \( P(-1, 1) \) has polar coordinates \( (\sqrt{2}, 3\pi/4), (\sqrt{2}, 11\pi/4), (\sqrt{2}, -5\pi/4) \) and \( (\sqrt{2}, -13\pi/4) \), for example. A polar form of \( z \) is \( \sqrt{2}(\cos \frac{3\pi}{4} + i \sin \frac{3\pi}{4}) \).

Since \( \tan^{-1}(y/x) = \tan^{-1}(-1) = -\pi/4 \), this does not provide an argument for \( z \), however. In particular, \( \text{Arg}(-1 + i) = -\frac{\pi}{4} + \pi = \frac{3\pi}{4} \).

\[ \text{DE MOIVRE'S THEOREM AND EULER'S FORMULA} \]

An important theorem concerning complex numbers is due to the French mathematician Abraham De Moivre. To prove this theorem, two identities from trigonometry will be useful. For real numbers \( A \) and \( B \),

\[
\sin(A + B) = \sin A \cos B + \cos A \sin B
\]
\[
\cos(A + B) = \cos A \cos B - \sin A \sin B.
\]

For complex numbers \( z_1 = r_1(\cos \theta_1 + i \sin \theta_1) \) and \( z_2 = r_2(\cos \theta_2 + i \sin \theta_2) \), their product can therefore be expressed as

\[
z_1z_2 = r_1r_2(\cos \theta_1 + i \sin \theta_1)(\cos \theta_2 + i \sin \theta_2)
\]
\[
= r_1r_2(\cos \theta_1 \cos \theta_2 - \sin \theta_1 \sin \theta_2) + i(\sin \theta_1 \cos \theta_2 + \cos \theta_1 \sin \theta_2)
\]
\[
= r_1r_2[\cos(\theta_1 + \theta_2) + i \sin(\theta_1 + \theta_2)].
\]

The following theorem was proved early in the 18th century.

**Theorem 18.34 (De Moivre’s Theorem)** For every positive integer \( n \),

\[
(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta.
\]

**Proof** We proceed by induction. Certainly the result holds for \( n = 1 \). Assume that

\[
(\cos \theta + i \sin \theta)^k = \cos k\theta + i \sin k\theta
\]

for a positive integer \( k \). Then

\[
(\cos \theta + i \sin \theta)^{k+1} = (\cos \theta + i \sin \theta)(\cos \theta + i \sin \theta)^k
\]
\[
= (\cos \theta + i \sin \theta)(\cos k\theta + i \sin k\theta)
\]
\[
= \cos(k + 1)\theta + i \sin(k + 1)\theta.
\]

The result then follows by the Principle of Mathematical Induction.

Let’s see how De Moivre’s theorem can be used to determine a power of a complex number.
Example 18.35  Determine \( \left( \frac{\sqrt{3}}{2} + \frac{1}{2}i \right)^6 \).

Solution  First, we express \( z = \frac{\sqrt{3}}{2} + \frac{1}{2}i \) in polar form. Since \( x = \frac{\sqrt{3}}{2} \) and \( y = \frac{1}{2} \), it follows that \( r = \sqrt{x^2 + y^2} = 1 \). Therefore, \( \cos \theta = x/r = \sqrt{3}/2 \) and \( \sin \theta = y/r = 1/2 \). Furthermore, \( \tan \theta = y/x = 1/\sqrt{3} \). Since \( \theta \) is an angle in the first quadrant, we can choose \( \theta = \pi/6 \), which is \( \text{Arg}(z) \), and so \( z = \cos \frac{\pi}{6} + i \sin \frac{\pi}{6} \). By De Moivre’s Theorem,
\[
z^6 = \left( \cos \frac{\pi}{6} + i \sin \frac{\pi}{6} \right)^6 = \cos \pi + i \sin \pi = -1.
\]

This also says that \( \frac{\sqrt{3}}{2} + \frac{1}{2}i \) is a root (one of the six roots) of the equation \( z^6 = -1 \). \( \diamondsuit \)

The solutions of the equation \( z^6 = 1 \) are 1 and \(-1\), of course. This equation can be solved by first rewriting it as \( z^2 - 1 = 0 \) and then factoring \( z^2 - 1 = (z - 1)(z + 1) = 0 \). To solve the equation \( z^3 = 1 \), we can write it as \( z^3 - 1 = 0 \) and then factor, obtaining
\[
z^3 - 1 = (z - 1)(z^2 + z + 1) = 0.
\]

Applying the quadratic formula to \( z^2 + z + 1 = 0 \), we have
\[
z = \frac{-1 \pm \sqrt{-3}}{2} = \frac{-1 \pm i \sqrt{3}}{2} = \frac{1}{2} \pm \frac{\sqrt{3}i}{2}.
\]
Therefore, the three roots of \( z^3 = 1 \) are \( 1, (-1 + i\sqrt{3})/2 \) and \( (-1 - i\sqrt{3})/2 \). The roots of the equation \( z^4 = 1 \) or, equivalently, \( z^4 - 1 = 0 \) are \( 1, -1, i, -i \). Observe that the solutions of all three of these equations are equally spaced points on the circle \( x^2 + y^2 = 1 \) in the complex plane (see Figure 18.3).

![Figure 18.3](image)

**Figure 18.3**  Location of roots of the equations \( z^n = 1 \) for \( n = 2, 3, 4 \)

For a complex number \( \alpha \), we now consider finding the \( n \) roots of the equation \( z^n = \alpha \), where \( n \) is a positive integer. That is, we seek the \( n \)th roots of \( \alpha \). As we have seen, \( \alpha \) can be expressed as \( \alpha = r(\cos \theta + i \sin \theta) \) or as \( \alpha = r(\cos(\theta + 2k\pi) + i \sin(\theta + 2k\pi)) \).
for some integer \( k \). If \( z_1 \) is a root of the equation \( z^n = \alpha \), then \( z_1^n = \alpha \). It follows by De Moivre’s theorem that \( z_1 \) can be expressed as \( z_1 = \sqrt[n]{\alpha} \left( \cos \left( \frac{\theta + 2k\pi}{n} \right) + i \sin \left( \frac{\theta + 2k\pi}{n} \right) \right) \) for some integer \( k \). Since the numbers \( \sqrt[n]{\alpha} \left( \cos \left( \frac{\theta + 2k\pi}{n} \right) + i \sin \left( \frac{\theta + 2k\pi}{n} \right) \right) \) are distinct when \( k \in \{0, 1, 2, \ldots, n-1\} \), it follows that these are the \( n \) distinct roots of \( z^n = \alpha \). We may therefore express the \( n \) roots of \( z^n = \alpha \) as \( z_0, z_1, \ldots, z_{n-1} \), where

\[
 z_k = \sqrt[n]{\alpha} \left( \cos \left( \frac{\theta + 2k\pi}{n} \right) + i \sin \left( \frac{\theta + 2k\pi}{n} \right) \right)
\]

for \( k \in \{0, 1, 2, \ldots, n-1\} \).

**Example 18.36** Find the three solutions of the equation \( z^3 = i \).

**Solution** First, observe that \( i = r(\cos \theta + i \sin \theta) \) where \( r = 1 \) and \( \theta = \frac{\pi}{2} \). Hence, the three roots \( z_0, z_1, z_2 \) of this equation are

\[
 z_k = \sqrt[3]{1} \left( \cos \left( \frac{\frac{\pi}{2} + 2k\pi}{3} \right) + i \sin \left( \frac{\frac{\pi}{2} + 2k\pi}{3} \right) \right)
\]

for \( k = 0, 1, 2 \). Therefore,

\[
 z_0 = \cos \frac{\pi}{6} + i \sin \frac{\pi}{6} = \frac{\sqrt{3}}{2} + \frac{1}{2}i
\]

\[
 z_1 = \cos \frac{5\pi}{6} + i \sin \frac{5\pi}{6} = -\frac{\sqrt{3}}{2} + \frac{1}{2}i
\]

\[
 z_2 = \cos \frac{3\pi}{2} + i \sin \frac{3\pi}{2} = -i
\]

which are then the three cube roots of \( i \). These three complex numbers are displayed in the complex plane in Figure 18.4.

![Figure 18.4](image-url)
Example 18.37 Determine the roots of the quadratic equation $z^2 + 2iz + (2 - 4i) = 0$.

Solution Applying the quadratic formula to this equation, where then $a = 1$, $b = 2i$ and $c = 2 - 4i$, we see that the roots are

$$z = \frac{1}{2} \left( -2i \pm \sqrt{(2i)^2 - 4 \cdot 1 \cdot (2 - 4i)} \right) = \frac{1}{2} \left( -2i \pm \sqrt{-12 + 16i} \right)$$

$$= \frac{1}{2} \left( -2i \pm 2\sqrt{-3 + 4i} \right) = -i \pm \sqrt{-3 + 4i}.$$

To express the roots in the rectangular form of a complex number, we seek real numbers $a$ and $b$ for which $(a + bi)^2 = -3 + 4i$ and so

$$a^2 + 2abi - b^2 = -3 + 4i.$$

Therefore, $a^2 - b^2 = -3$ and $2ab = 4$. Substituting $b = 2/a$ into $a^2 - b^2 = -3$, we obtain

$$a^4 + 3a^2 - 4 = 0 \text{ or } (a^2 - 1)(a^2 + 4) = 0.$$

Since $a \in \mathbb{R}$, either $a = 1$ or $a = -1$. If $a = 1$, then $b = 2$; while if $a = -1$, then $b = -2$. In either case,

$$\pm \sqrt{-3 + 4i} = \pm (1 + 2i)$$

and so the solutions of this equation are

$$z_1 = -i + (1 + 2i) = 1 + i \text{ and } z_2 = -i - (1 + 2i) = -1 - 3i.$$

Furthermore, $z^2 + 2iz + (2 - 4i) = [z - (1 + i)][z - (-1 - 3i)].$

Recall from calculus that the power series

$$1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \frac{x^4}{4!} + \cdots$$

converges to $e^x$ for every real number $x$. Therefore, for every real number $\theta$,

$$e^{i\theta} = 1 + \theta + \frac{\theta^2}{2!} + \frac{\theta^3}{3!} + \frac{\theta^4}{4!} + \cdots.$$

Also, for every real number $\theta$, the following are convergent series:

$$\cos \theta = 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - \frac{\theta^6}{6!} + \cdots$$

$$\sin \theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \frac{\theta^7}{7!} + \cdots.$$

Therefore, for every real number $\theta$,

$$e^{i\theta} = 1 + (i\theta) + \frac{(i\theta)^2}{2!} + \frac{(i\theta)^3}{3!} + \frac{(i\theta)^4}{4!} + \cdots$$

$$= \left( 1 - \frac{\theta^2}{2!} + \frac{\theta^4}{4!} - \frac{\theta^6}{6!} + \cdots \right) + i \left( \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \frac{\theta^7}{7!} + \cdots \right)$$

$$= \cos \theta + i \sin \theta.$$
This gives us the following formula named for the famous mathematician Leonhard Euler.

**Theorem 18.38** (Euler’s Formula) For every real number \( \theta \),

\[
e^{i\theta} = \cos \theta + i \sin \theta.
\]

When \( \theta = \pi \), Euler’s Formula results in \( e^{i\pi} = \cos \pi + i \sin \pi = -1 + i0 = -1 \) or

The Euler Identity \( e^{i\pi} + 1 = 0 \).

This amazing identity discovered by Euler ties together in a very basic way what might be considered the five most important numbers in mathematics:

- **0** : the additive identity: \( 0 + r = r \) for every \( r \in \mathbb{R} \)
- **1** : the multiplicative identity: \( 1 \cdot r = r \) for every \( r \in \mathbb{R} \)
- **i** : the fundamental imaginary number
- **\( \pi \)** : the fundamental circular constant from geometry
- **e** : the base of natural logarithms.

In 1988 the British mathematician and mathematics educator David Wells wrote an article in the journal *The Mathematical Intelligencer* discussing mathematical theorems and which of these are the most beautiful. He asked the readers to vote on this question as well. In 1990 he wrote another article giving the results of the vote. The Euler Identity came out on top.

Since the polar representation of a complex number \( z \) is \( r(\cos \theta + i \sin \theta) \), it follows by Euler’s Formula that \( z \) can be expressed as \( z = re^{i\theta} \).

---

**EXERCISES FOR CHAPTER 18**

18.1. Let \( a, b, c \in \mathbb{R} \). Prove each of the following.

(a) Exactly one of the following holds: (i) \( a > b \), (ii) \( a = b \), (iii) \( a < b \).
(b) If \( a > b \) and \( b > c \), then \( a > c \).
(c) If \( a > b \), then \( a + c > b + c \).
(d) If \( a > b \) and \( c > 0 \), then \( ac > bc \).
(e) If \( a \neq 0 \), then \( a^2 = a \cdot a > 0 \).

18.2. Let \( a, b, c, d \in \mathbb{R} \). Prove or disprove the following: If \( a > b \) and \( c > d \), then \( ac > bd \).

18.3. We know, for every \( a \in \mathbb{R} \), that \( a > 0 \), \( a = 0 \) or \( a < 0 \) and that for \( a, b \in \mathbb{R} \) for which \( a > 0 \) and \( b > 0 \) that \( a + b > 0 \) and \( ab > 0 \). Determine all nonnegative real numbers \( c \) for which the following two properties are satisfied:

(1) If \( a \in \mathbb{R} \), then exactly one of the following holds: \( a > c, a = c, a < c \).
(2) If \( a, b \in \mathbb{R} \) such that \( a > c \) and \( b > c \), then \( a + b > c \) and \( ab > c \).

18.4. Let \( F = \{ a + b\sqrt{2} : a, b \in \mathbb{Q} \} \).

(a) Show that \( \mathbb{Q} \subset F \subset \mathbb{R} \).
(b) Show that \( F \) is an ordered field.
24 Chapter 18 Proofs with Real and Complex Numbers

18.5. We saw that the field \( \mathbb{Z}_2 \) is not an ordered field. Show, for every odd prime \( p \), that \( \mathbb{Z}_p \) is also not an ordered field.

18.6. Show that the set \( \mathbb{Z} \) of integers is not an ordered field.

18.7. Prove that if \( F \) is an ordered field such that \( F \subseteq \mathbb{R} \), then \( \mathbb{Q} \subseteq F \).

18.8. For each of the following sets \( S \) of real numbers, determine \( \sup(S) \) and \( \inf(S) \) if these exist. Also, determine \( \max(S) \) and \( \min(S) \) if these exist.

(a) \( S = \{4, 4.9, 4.99, 4.999, \ldots\} \)
(b) \( S = \{r \in \mathbb{Q} : r^2 \leq 9\} \)
(c) \( S = \left\{1 + \frac{(-1)^n}{n} : n \in \mathbb{N}\right\} \)
(d) \( S = \left\{\frac{(-1)^n}{n+1} : n \in \mathbb{N}\right\} \)
(e) \( S = \{x \in \mathbb{R} : x^2 - 5x < 6\} \)
(f) \( S = \left\{\frac{1}{n+1} : x \in \mathbb{R}\right\} \)
(g) \( S = \left\{\sum_{k=1}^{n} \frac{1}{k^2} : n \in \mathbb{N}\right\} \)
(h) \( S = \bigcup_{n \in \mathbb{N}} A_n \), where \( A_n = \left(\frac{1}{n}, \frac{1}{n} + \frac{1}{n}\right) \) for \( n \in \mathbb{N} \)
(i) \( S = \left\{\frac{1}{m} + \frac{1}{n} : m, n \in \mathbb{N}\right\} \).

18.9. Let \( S \) be a nonempty set of real numbers for which \( \inf(S) \) and \( \sup(S) \) exist.

(a) Prove that \( \inf(S) \leq \sup(S) \).
(b) State and prove a necessary and sufficient condition for \( S \) to have the property that \( \inf(S) = \sup(S) \).

18.10. Give an example of a bounded infinite set \( S \) of irrational numbers such that both \( \inf(S) \) and \( \sup(S) \) are rational numbers.

18.11. Let \( S \) be a nonempty set of real numbers such that both \( \inf(S) \) and \( \sup(S) \) exist and let \( T \) be a nonempty subset of \( S \).

(a) Prove that \( \inf(T) \) and \( \sup(T) \) exist.
(b) Prove that \( \inf(S) \leq \inf(T) \leq \sup(T) \leq \sup(S) \).

18.12. Let \( A \) and \( B \) be nonempty sets of real numbers such that both \( \sup(A) \) and \( \sup(B) \) exist.

(a) Does \( \sup(A \cap B) \) exist?
(b) Prove that if \( \sup(A \cap B) \) exists, then \( \sup(A \cap B) \leq \min(\sup(A), \ \sup(B)) \).
(c) Prove or disprove: \( \sup(A \cap B) = \min(\sup(A), \ \sup(B)) \).

18.13. Let \( S \) be a nonempty set of real numbers. Prove that \( a = \inf(S) \) if and only if \( a \) is a lower bound for \( S \) and for every real number \( y > a \), there exists \( x \in S \) such that \( a \leq x < y \).

18.14. Let \( A \) be a nonempty subset of \( \mathbb{R} \) and let \( f : A \to \mathbb{R} \) and \( g : A \to \mathbb{R} \) be functions such that both \( f(A) \) and \( g(A) \) are bounded sets.

(a) Prove that \( \sup(f(A) + g(A)) \leq \sup(f(A)) + \sup(g(A)) \).
(b) Prove that \( \inf(f(A) + g(A)) \geq \inf(f(A)) + \inf(g(A)) \).
(c) Give an example of a nonempty set \( A \) of real numbers and functions \( f : A \to \mathbb{R} \) and \( g : A \to \mathbb{R} \) such that the inequalities in (a) and (b) are strict.

18.15. Without using the Archimedean Principle or the Completeness Axiom, prove that if \( r \) is a positive rational number, then there exists a positive integer \( n \) such that \( n > \sqrt{r} \).

18.16. For an irrational number \( a \), let \( S = \{x \in \mathbb{Q} : x > a\} \). Prove that \( \inf(S) = a \).

18.17. Let \( a, b \in \mathbb{R} \) such that \( a < b \). Show that \( S = \{r \in \mathbb{Q} : r \in (a, b)\} \) is an infinite set.
18.18. Let \( S \) be a nonempty bounded set of real numbers having no maximum element. Prove that if \( s \in S \), then \( \sup(S) = \sup(S - \{s\}) \).

18.19. Let \( S = \{\sqrt{2}r : r \in \mathbb{Q}\} \). Is the set \( S \) dense in \( \mathbb{R} \)?

18.20. Let \( x \) be a real number.

(a) Prove that there exists a unique least integer \( n \) such that \( n \geq x \). (Recall that \( n \) is called the ceiling of \( x \) and is denoted by \( \lceil x \rceil \).)

(b) Prove that there exists a unique greatest integer \( \ell \) such that \( \ell \leq x \). (Recall that \( \ell \) is called the floor of \( x \) and is denoted by \( \lfloor x \rfloor \).)

18.21. (a) Prove that the union of a finite number of bounded sets is bounded.

(b) Prove that if \( A_1, A_2, \ldots, A_n \) are bounded sets, then

\[
\sup(A_1 \cup A_2 \cup \cdots \cup A_n) = \max(\sup(A_1), \sup(A_2), \ldots, \sup(A_n))
\]

and

\[
\inf(A_1 \cup A_2 \cup \cdots \cup A_n) = \min(\inf(A_1), \inf(A_2), \ldots, \inf(A_n)).
\]

18.22. Prove that the interior of every set of real numbers is open.

18.23. (a) Prove that if \( S \) and \( T \) are open sets of real numbers that are dense in \( \mathbb{R} \), then \( S \cap T \) is dense in \( \mathbb{R} \).

(b) Is the result in (a) true if only one of \( S \) and \( T \) is an open set?

(c) Is the result in (a) true if neither \( S \) nor \( T \) is an open set?

18.24. Show that a set \( S \) of real numbers is closed if and only if \( \overline{S} \subseteq \text{Int}(\overline{S}) \).

18.25. Prove that if \( S \) and \( T \) are sets of real numbers, then \( \text{Int}(S) \cap \text{Int}(T) = \text{Int}(S \cap T) \).

18.26. Give an example of nonempty sets \( A \) and \( B \) of real numbers such that \( \mathbb{R} = A \cup B \) and \( \text{Int}(A) \cap \text{Int}(B) = \emptyset \).

18.27. (a) Prove that if \( A \) and \( B \) are two nonempty disjoint open sets of real numbers, then \( A \cup B \neq \mathbb{R} \).

(b) Prove that the only sets of real numbers that are both open and closed are \( \mathbb{R} \) and \( \emptyset \).

18.28. Let \( A_n = [a_n, b_n] \) be a closed interval of real numbers for each \( n \in \mathbb{N} \) where then \( a_n \leq b_n \). Prove that if \( A_{n+1} \subseteq A_n \) for each \( n \in \mathbb{N} \), then \( \bigcap_{n=1}^{\infty} A_n \neq \emptyset \).

18.29. For each subset \( S \) of \( \mathbb{R} \) given below, classify \( S \) as either (1) open, (2) closed, (3) both open and closed or (4) neither open nor closed. Also, determine \( \text{Bd}(S) \) and \( \text{Int}(S) \) in each case.

\[
\begin{align*}
(a) \quad S &= [1, 2] \cup [3, 4] \cup [5, 6] \cup \cdots \cup [2001, 2002] \\
(b) \quad S &= [x \in \mathbb{R} : |x - 3| < 5] \\
(c) \quad S &= [x \in \mathbb{R} : 0 < x^2 < 9] \\
(d) \quad S &= \bigcap_{n=1}^{\infty} (1 - \frac{1}{n}, 1 + \frac{1}{n}) \\
(e) \quad S &= \bigcap_{n=1}^{\infty} (0, 1 + \frac{1}{n}).
\end{align*}
\]

18.30. For the subset \( S = \{a + b\sqrt{2} : a, b \in \mathbb{Q}\} \) of \( \mathbb{R} \), prove that \( \text{Bd}(S) = \mathbb{R} \).

18.31. In each part below, give an example of a set \( S \) of real numbers satisfying the specified condition.

(a) \( \text{Acc}(S) \cap \text{Acc}(\overline{S}) = [1, 2] \)

(b) \( \text{Bd}(S) \cap \text{Bd}(\overline{S}) = \emptyset \)

(c) \( \text{Cl}(S) \cap \text{Cl}(\overline{S}) = [1] \).

18.32. Classify each set \( S \) of real numbers below as either (1) open, (2) closed, (3) both open and closed or (4) neither open nor closed. Also, determine \( \text{Bd}(S) \), \( \text{Cl}(S) \), \( \text{Int}(\text{Cl}(S)) \) and \( \text{Cl}(\text{Int}(S)) \) in each case.

\[
\begin{align*}
(a) \quad S &= (-2, 5) \cup (3, 6) \quad (b) \quad S &= \mathbb{Z} \quad (c) \quad S &= (-1, 1] \cup [2, 5) \\
(d) \quad S &= \{x \in \mathbb{Q} : |x - 5| \geq 2\} \quad (e) \quad S &= \bigcup_{n=1}^{\infty} (1 - \frac{1}{n}, 1) \quad (f) \quad S &= \bigcup_{n=1}^{\infty} \left[ \frac{1}{n}, 1 \right].
\end{align*}
\]

18.33. Give an example of a set \( S \) of real numbers such that \( \text{Acc}(S) \) is an infinite set that is disjoint from \( S \).
26  Chapter 18  Proofs with Real and Complex Numbers

18.34. Give an example of the following.
   (a) A nonempty set $S$ of real numbers such that $\text{Bd}(S) = \emptyset$.
   (b) A nonempty set $S$ of real numbers such that $\text{Bd}(S) = \text{Cl}(S)$.
   (c) A collection $\mathcal{F} = \{A_n\}_{n \in \mathbb{N}}$ of nonempty open sets such that $\bigcap_{n=1}^{\infty} A_n$ is not open.
   (d) A collection $\mathcal{F} = \{A_n\}_{n \in \mathbb{N}}$ of nonempty closed sets such that $\bigcup_{n=1}^{\infty} A_n$ is not closed.

18.35. (a) Prove that if $S$ and $T$ are sets of real numbers, then $\text{Cl}(S \cap T) \subseteq \text{Cl}(S) \cap \text{Cl}(T)$.
   (b) Give an example of sets $A$ and $B$ of real numbers such that $\text{Cl}(A \cap B) \neq \text{Cl}(A) \cap \text{Cl}(B)$.

18.36. Let $S$ be a set of real numbers for which $\inf(S)$ exists. Let $\inf(S) = c$.
   (a) Prove, for every real number $\epsilon > 0$, that $S \cap N_\epsilon(c) \neq \emptyset$.
   (b) Prove that if $S$ is a closed set, $\min(S)$ exists and $\min(S) = c$.

18.37. For each part below, give an example of a set $S$ of real numbers such that $\text{Bd}(S) \neq \emptyset$ and $\text{Acc}(S) \neq \emptyset$ that satisfies the condition.
   (a) $\text{Bd}(S) \subset \text{Acc}(S)$
   (b) $\text{Acc}(S) \subset \text{Bd}(S)$
   (c) $\text{Bd}(S) = \text{Acc}(S)$.

18.38. Prove that $\text{Acc}(S)$ is a closed set for every set $S$ of real numbers.

18.39. (a) Let $S$ be a set of real numbers such that $\text{Bd}(S) \neq \emptyset$ and $\text{Bd}(S) \cap \text{Acc}(S) = \emptyset$. Show that (1) $S$ is a closed set, (2) $S = \text{Int}(S) \cup \text{Bd}(S)$ and (3) $\text{Int}(S) = \text{Acc}(S)$.
   (b) Prove that there exists no set $S$ of real numbers for which $\text{Bd}(S) \neq \emptyset$, $\text{Acc}(S) \neq \emptyset$ and $\text{Bd}(S) \cap \text{Acc}(S) = \emptyset$.

18.40. Let $S$ be a set of real numbers. Prove that $c \in S$ is an accumulation point of $S$ if and only if each neighborhood of $c$ contains infinitely many points of $S$.

18.41. For each of the following sets $S$ of real numbers, determine $\text{Bd}(S)$, $\text{Cl}(S)$, $\text{Int}(S)$ and $\text{Cl}(S) - \text{Int}(S)$.
   (a) $S = [0, 1) \cup (2, 3)$  (b) $S = \left\{ \frac{1}{n} : n \in \mathbb{N} \right\}$  (c) $S = (-\infty, 0) \cup \mathbb{N}$.

18.42. Exercise 18.41 may suggest that $\text{Bd}(S) = \text{Cl}(S) - \text{Int}(S)$ for every set $S$ of real numbers. Prove that this is, in fact, the case.

18.43. For each of the following, either give an example of a set $S$ of real numbers that satisfies the given condition or show that no such example exists.
   (a) $\text{Acc}(\text{Acc}(S)) \neq \text{Acc}(S)$
   (b) $\text{Bd}(\text{Bd}(S)) \neq \text{Bd}(S)$
   (c) $\text{Cl}(\text{Cl}(S)) \neq \text{Cl}(S)$
   (d) $\text{Int}(\text{Int}(S)) \neq \text{Int}(S)$.

18.44. Give an example of a set $S$ of real numbers such that $\text{Acc}(\text{Acc}(\text{Acc}(S))) \neq \text{Acc}(\text{Acc}(S))$.

18.45. Prove, for every set $S$ of real numbers, that $\mathbb{R} = \text{Int}(S) \cup \text{Bd}(S) \cup \text{Int}(\overline{S})$.

18.46. Prove that $\overline{\text{Int}(S)} = \text{Int}(\overline{S})$ for every set $S$ of real numbers.

18.47. Let $S$ be a set of real numbers and let $T = \{L : L$ is an open set with $L \subseteq S\}$. Prove that $\text{Int}(S) = \bigcup_{L \in T} L$.

18.48. Let $S$ be a set of real numbers and let $T = \{K : K$ is a closed set with $S \subseteq K\}$. Prove that $\text{Cl}(S) = \bigcap_{K \in T} K$.

18.49. Let $S$ be a nonempty compact set of real numbers with the property that every open cover of $S$ contains a subcover consisting of a single set belonging to the open cover. What is $S$?
18.50. Prove that a set $S$ of real numbers is compact if and only if for every collection $\{T_\alpha\}_{\alpha \in I}$ of closed sets for which $\bigcap_{\alpha \in I} T_\alpha \subseteq S$, there exists a finite subcollection $\{T_\alpha\}_{\alpha \in J}$ of these sets for which $\bigcap_{\alpha \in J} T_\alpha \subseteq S$.

18.51. Determine which of the following sets are compact.

(a) $S = [-1000, 1000]$. 
(b) $S = (0, 2]$, where $f : \mathbb{R} \rightarrow \mathbb{R}$ is defined by $f(x) = x^2 + 2$.
(c) $S = \{\frac{1}{n} : n \in \mathbb{N}\} \cup \{0\}$. 
(d) $S = (1, \infty)$, where $f : [1, \infty) \rightarrow \mathbb{R}$ is defined by $f(x) = \frac{1}{x}$.
(e) $S = \{1\} \cup \bigcup_{n=1}^{10} [n, n + 1)$.

18.52. Let $S$ be the open interval $(0, 2)$ and let $S_n = \left(\frac{1}{n}, 2\right)$ for $n \in \mathbb{N}$.

(a) Prove that $C = \{S_n\}_{n \in \mathbb{N}}$ is an open cover of $S$.
(b) Prove that $C$ contains no finite subcover of $S$.

18.53. Let $S = \{\frac{1}{n} : n \in \mathbb{N}\}$. Give an example of an open cover of $S$ that contains no finite subcover.

18.54. Use the definition of compact sets to show that the set $S = [0, \infty)$ is not compact.

18.55. Show that the set $S = \{x \in \mathbb{Q} : 0 \leq x \leq 2\}$ is not compact.

(a) by applying Theorem 18.27.
(b) by using the definition of a compact set.

18.56. Prove or disprove the following.

(a) If $S$ is a set of real numbers and $K$ is a compact set of real numbers, then $S \cap K$ is compact.
(b) Every finite set of real numbers is compact.
(c) Let $S$ be a set of real numbers and let $C$ be an open cover of $S$ consisting of an infinite number of open sets, no one of which contains $S$. If $C$ contains a finite subcover of $S$, then $S$ is compact.
(d) If the intersection of an infinite collection of open sets is nonempty, then this intersection is not a compact set.

18.57. (a) Prove that every closed subset of a compact set of real numbers is compact.
(b) Prove that if $S$ is a compact set of real numbers and $K$ is a nonempty closed subset of $S$, then $K$ has both a maximum and a minimum element.

18.58. Let $S$ be a set of real numbers and let $\{S_\alpha\}_{\alpha \in I}$ be an open cover of $S$. Prove that a set $S$ of real numbers is compact if and only if every cover $C$ of $S$ of the form $C = \{S_\alpha \cap S : S_\alpha \text{ is an open set for each } \alpha \in \text{an index set } I\}$ contains a finite subcover of $S$.

18.59. Prove that a set $S$ of real numbers is bounded if and only if $\text{Cl}(S)$ is compact.

18.60. (a) Prove that the union of a finite number of nonempty compact sets of real numbers is compact.
(b) Show that the union of an infinite number of nonempty compact sets of real numbers may not be compact.

18.61. Prove that the intersection of an infinite number of nonempty compact sets of real numbers is compact.

18.62. Prove, for every real number $r$ and every compact set $S$, that the set $T = \{x + r : x \in S\}$ is also compact.

18.63. (a) Prove that if $A$ and $B$ are open sets of real numbers such that $A \cap B$ is a compact set, then $A \cap B = \emptyset$.
(b) Prove or disprove: There exists an infinite collection of open sets of real numbers whose intersection is a nonempty compact set.

18.64. (a) Prove or disprove: Every bounded set of real numbers consisting of isolated points is finite.
(b) Prove or disprove: Every closed, bounded set of real numbers consisting of isolated points is finite.

18.65. Prove, for every compact set $S$ of real numbers and every real number $r \notin S$, that there exist disjoint open sets $U$ and $V$ such that $S \subseteq U$ and $r \in V$. 

Exercises for Chapter 18
28 Chapter 18 Proofs with Real and Complex Numbers

18.66. Prove, for every two disjoint compact sets \( S \) and \( T \) of real numbers, that there exist disjoint open sets \( U \) and \( V \) such that \( S \subseteq U \) and \( T \subseteq V \).

18.67. Prove that a set \( S \) of real numbers is compact if and only if every infinite subset of \( S \) has an accumulation point belonging to \( S \).

18.68. Express the sum, difference, product and quotient of the following pairs of complex numbers in rectangular form.
   
   (a) \( 1 + i, 1 + 2i \)  
   (b) \( 2 - i, 3 - 4i \)  
   (c) \( 4i, 1/(3 - i) \)  
   (d) \( 3 + 7i, 3 - 7i \)  
   (e) \( i^3, 1 + i^4 \).

18.69. Express each of the following complex numbers in rectangular form.
   
   (a) \( (3 - i)^2 \)  
   (b) \( (1 + 2i)^3 \)  
   (c) \( i^3(3 + 2i)^3 \)  
   (d) \( \frac{3+i}{1+i} \)  
   (e) \( (2 + i)(1 - 3i)(4 - 5i) \)  
   (f) \( \frac{(1 + i^6)}{1 - i^7} \).

18.70. Express each of the following complex numbers in rectangular form.
   
   (a) \( \frac{12}{\sqrt{3}i} \)  
   (b) \( \frac{4}{1 + \sqrt{3}i} \)  
   (c) \( \frac{5}{3 + 4i} \)  
   (d) \( \frac{25}{4 - 3i} \).

18.71. Show that \( \sqrt{2} + i \) is a cube root of \( -\sqrt{2} + 5i \).

18.72. Determine \( i^n \) for every positive integer \( n \).

18.73. Prove the following for complex numbers \( z, z_1 \) and \( z_2 \).
   
   (a) \( \overline{\overline{z}} = z \)  
   (b) \( \overline{z_1 + z_2} = \overline{z_1} + \overline{z_2} \)  
   (c) \( \overline{z_1 z_2} = \overline{z_1} \cdot \overline{z_2} \).

18.74. Prove, for every \( n \) complex numbers \( \alpha_1, \alpha_2, \ldots, \alpha_n \) where \( n \in \mathbb{N} \), that 
   
   \[ \overline{\alpha_1 + \alpha_2 + \cdots + \alpha_n} = \overline{\alpha_1} + \overline{\alpha_2} + \cdots + \overline{\alpha_n} \].

18.75. (a) Prove, for every \( n \) complex numbers \( \alpha_1, \alpha_2, \ldots, \alpha_n \) where \( n \in \mathbb{N} \), that
   
   \[ \overline{\alpha_1 \cdot \alpha_2 \cdots \alpha_n} = \overline{\alpha_1} \overline{\alpha_2} \cdots \overline{\alpha_n} \].

   (b) Prove for each \( \alpha \in \mathbb{C} \) that \( \overline{\alpha^n} = \overline{\alpha}^n \) for every \( n \in \mathbb{N} \).

18.76. Find two positive real numbers \( a \) and \( b \) such that the product of the four complex numbers \( z = a + bi \), \( \overline{z} \), \( -z \) and \( -\overline{z} \) is 4.

18.77. For a positive real number \( a \), determine the roots of the quadratic equation \( z^2 + 2az + 5a^2 = 0 \).

18.78. Find the solutions of the quadratic equation \( z^2 + \sqrt{3}z + 3i = 0 \).

18.79. Use the fact that \( (\sqrt{3} + \sqrt{3}i)^2 = 6i \) to find the solutions of the equation \( z^2 - 6z + 9 = 6i \).

18.80. Let \( z_1, z_2 \in \mathbb{C} \). Prove that \( z_1 z_2 = 0 \) if and only if \( z_1 = 0 \) or \( z_2 = 0 \).

18.81. Solve the following equations.
   
   (a) \( z^2 - 2z + 2 = 0 \)  
   (b) \( z^4 - 16 = 0 \)  
   (c) \( z^3 - 3z^2 + z - 3 = 0 \)  
   (d) \( z^4 + 3z^2 + 2 = 0 \).

18.82. Given that \( i \) is a root of the equation \( z^7 + 6z^6 - cz^3 + dz^2 - 1 = 0 \), determine the real numbers \( c \) and \( d \).

18.83. Let \( p(z) = a_0 + a_1z + a_2z^2 + \cdots + a_nz^n \) where \( a_i \in \mathbb{R} \) for \( 0 \leq i \leq n \). Use Exercises 18.74 and 18.75 to prove that if \( p(\alpha) = 0 \) for some \( \alpha \in \mathbb{C} \), then \( p(\overline{\alpha}) = 0 \).

18.84. Determine all complex numbers \( z \) satisfying each of the following.
   
   (a) \( z^2 = -8i \)  
   (b) \( z(2 + 3i) = 5 + i \)  
   (c) \( z^2 + 2z = -1 \).
18.85. Prove Theorem 18.31: For complex numbers \( z_1 = a + bi \) and \( z_2 = c + di \), where \( a, b, c, d \in \mathbb{R} \),

(a) \( |z_1|^2 = z_1 \cdot \overline{z_1} = a^2 + b^2 \).
(b) \( |\text{Re}(z_1)| \leq |z_1| \) and \( |\text{Im}(z_1)| \leq |z_1| \).
(c) \( |z_1| = |z| \) and \( |z_1| = |\overline{z}| \).
(d) \( |z_1 z_2| = |z_1| |z_2| \) and for \( z_2 \neq 0 \), \( \frac{|z_1|}{|z_2|} = \frac{z_1}{z_2} \).

18.86. (a) Prove, for every \( n \) complex numbers \( \alpha_1, \alpha_2, \ldots, \alpha_n \) where \( n \in \mathbb{N} \), that

\[ |\alpha_1 \cdot \alpha_2 \cdots \alpha_n| = |\alpha_1| |\alpha_2| \cdots |\alpha_n|. \]

(b) Prove, for every complex number \( \alpha \), that \( |\alpha^n| = |\alpha|^n \) for every positive integer \( n \).

18.87. Use Exercise 18.86 to determine \( |z| \) for each of the following.

(a) \( z = (1 - \sqrt{3}i)(4 + 3i)(12 - 5i) \) \hspace{1cm} (b) \( z = (3 - i)^6 \).

18.88. Prove, for every \( n \geq 2 \) complex numbers \( z_1, z_2, \ldots, z_n \), that

\[ |z_1 + z_2 + \cdots + z_n| \leq |z_1| + |z_2| + \cdots + |z_n|. \]

18.89. Use Exercise 18.88 to show for complex numbers \( z_1 \) and \( z_2 \) that \( |z_1 - z_2| \geq |z_1| - |z_2| \).

18.90. Prove, for the complex number \( z = a + bi \) where \( a, b \in \mathbb{R} \), that

\[ \frac{|a| + |b|}{\sqrt{2}} \leq |z| \leq |a| + |b|. \]

18.91. Express each of the following complex numbers in polar form.

(a) \( \sqrt{3} + i \) \hspace{1cm} (b) \( -\sqrt{3} - i \) \hspace{1cm} (c) \( 1 - \sqrt{3}i \)
(d) \( 5 \) \hspace{1cm} (e) \( 4 - 4i \) \hspace{1cm} (f) \( 2\sqrt{3} - 2i \).

18.92. Find the principal argument of each of the following complex numbers.

(a) \( -3 - 3i \) \hspace{1cm} (b) \( -5 \) \hspace{1cm} (c) \( -1 + \sqrt{3}i \) \hspace{1cm} (d) \( -i \).

18.93. Find the rectangular form of the complex numbers having the following polar representations.

(a) \( \sqrt{2} \left( \cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right) \) \hspace{1cm} (b) \( 2 \left( \cos \left(-\frac{\pi}{3}\right) + i \sin \left(-\frac{\pi}{3}\right) \right) \)
(c) \( 2 \left( \cos \frac{5\pi}{6} + i \sin \frac{5\pi}{6} \right) \) \hspace{1cm} (d) \( 4 \left( \cos \frac{\pi}{2} + i \sin \frac{\pi}{2} \right) \).

18.94. Determine \( (1 + i)^{10} \).

18.95. Determine \( (-1 - \sqrt{3}i)^{12} \).

18.96. Express each of the following complex numbers in rectangular form.

(a) \( (1 - i)^{15} \) \hspace{1cm} (b) \( (1 - \sqrt{3}i)^{10} \) \hspace{1cm} (c) \( (2 + 2i)^9 \) \hspace{1cm} (d) \( \left[ 5 \left( \cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right) \right]^7 \)
(e) \( \left[ 3 \left( \cos \frac{3\pi}{4} + i \sin \frac{3\pi}{4} \right) \right]^5 \) \hspace{1cm} (f) \( \left[ 2 \left( \cos \left(-\frac{3\pi}{2}\right) + i \sin \left(-\frac{3\pi}{2}\right) \right) \right]^8 \).

18.97. Use the fact that the roots of the equation \( z^n - 1 = 0 \) are equally spaced points on a circle in the complex plane to obtain the roots of this equation.

18.98. Find the roots of the equation \( z^4 = -1 \) and plot these roots in the complex plane.

18.99. Determine \( \alpha \) if \( \left( \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}i \right)^8 = \alpha \). Then determine the roots of the equation \( z^8 - \alpha = 0 \).

18.100. Use De Moivre’s theorem to verify the following trigonometric identities.

(a) \( \cos(3\theta) = \cos^3 \theta - 3 \cos \theta \sin^2 \theta \) \hspace{1cm} (b) \( \sin(3\theta) = 3 \cos^2 \theta \sin \theta - \sin^3 \theta \).
Chapter 18  Proofs with Real and Complex Numbers

18.101. Express each of the following complex numbers as \( re^{i\theta} \) for real numbers \( r \) and \( \theta \).
   (a) \( 3 + 4i \)  (b) \( 2 - 2i \)  (c) \( -\sqrt{3} + i \).

18.102. Express the complex number \( \arctan(1)e^{i\arctan(1)} \) in rectangular form.

18.103. Determine the two complex numbers (expressed in rectangular form) whose square is \( 3e^{\frac{\pi}{3}i} \).

18.104. (a) Determine the roots of the quadratic equation \((1 + i)z^2 - (1 + 3i)z - (2 - 2i) = 0\).
   (b) Prove that if \( p(z) \) is a quadratic polynomial all of whose nonzero coefficients are complex numbers that are not real numbers and whose two roots are real numbers, then there exists a complex number \( \alpha \) such that \( \alpha p(z) \) is a quadratic polynomial all of whose nonzero coefficients are real numbers.
19

Proofs in Topology

Recall from calculus that a function \( f : X \to \mathbb{R} \), where \( X \subseteq \mathbb{R} \), is continuous at \( a \in X \) if for every \( \epsilon > 0 \), there exists \( \delta > 0 \) such that if \( |x - a| < \delta \), then \( |f(x) - f(a)| < \epsilon \). When we write \( |x - a| \), we are referring to how far apart \( x \) and \( a \) are, that is, the distance between them. Similarly, \( |f(x) - f(a)| \) is the distance between \( f(x) \) and \( f(a) \). It is not surprising that distance enters the picture here since when we say that \( f \) is continuous at \( a \), we mean that if \( x \) is a number that is close to \( a \), then \( f(x) \) is close to \( f(a) \). The term “close” only has meaning once we understand how we are measuring the distances between the two pairs of numbers involved. It might seem obvious that the distance between two real numbers \( x \) and \( y \) is \( |x - y| \); however, it turns out that the distance between \( x \) and \( y \) need not be defined as \( |x - y| \), although it is certainly the most common definition. Furthermore, when the continuity of a function \( f : A \to B \) is being considered, it is not essential that \( A \) and \( B \) be sets of real numbers. That is, it is possible to place these concepts of calculus in a more general setting. The area of mathematics that deals with this is topology.

19.1 METRIC SPACES

We have already mentioned that the distance between two real numbers \( x \) and \( y \) is given by \( |x - y| \). There are four properties that this distance has, which will turn out to be especially interesting to us:

\[
\begin{align*}
(1) & \quad |x - y| \geq 0 \text{ for all } x, y \in \mathbb{R}; \\
(2) & \quad |x - y| = 0 \text{ if and only if } x = y \text{ for all } x, y \in \mathbb{R}; \\
(3) & \quad |x - y| = |y - x| \text{ for all } x, y \in \mathbb{R}; \\
(4) & \quad |x - z| \leq |x - y| + |y - z| \text{ for all } x, y, z \in \mathbb{R}.
\end{align*}
\]

Many of the fundamental results from calculus depend on these four properties. Using these properties as our guide, we now define distance in a more general manner.

Let \( X \) be a nonempty set and let \( d : X \times X \to \mathbb{R} \) be a function from the Cartesian product \( X \times X \) to the set \( \mathbb{R} \) of real numbers. Hence, for each ordered pair \((x, y) \in X \times X\), it follows that \( d((x, y)) \) is a real number. Once again, for simplicity, we write \( d(x, y) \)
Chapter 19  Proofs in Topology

rather than \( d((x, y)) \) and refer to \( d(x, y) \) as the **distance** from \( x \) to \( y \). The distance \( d \) is called a **metric** on \( X \) if it satisfies the following properties:

1. \( d(x, y) \geq 0 \) for all \( x, y \in X \);
2. \( d(x, y) = 0 \) if and only if \( x = y \) for all \( x, y \in \mathbb{R} \);
3. \( d(x, y) = d(y, x) \) for all \( x, y \in X \) (**symmetric property**);
4. \( d(x, z) \leq d(x, y) + d(y, z) \) for all \( x, y, z \in X \) (**triangle inequality**).

A set \( X \) together with a metric \( d \) defined on \( X \) is called a **metric space** and is denoted by \( (X, d) \). Since the set \( \mathbb{R} \) of real numbers together with the distance \( d \) defined on \( \mathbb{R} \) by \( d(x, y) = |x - y| \) satisfies the properties listed in (19.1), it follows that \( (\mathbb{R}, d) \) is a metric space.

We now consider two other ways of defining distance between two real numbers.

**Example 19.1**  For \( X = \mathbb{R} \), let the distance \( d : X \times X \to \mathbb{R} \) be defined by \( d(x, y) = x - y \). Determine which of the four properties of a metric are satisfied by this distance.

**Solution**  Since \( d(1, 2) = -1 \), property 1 is not satisfied. On the other hand, since \( d(x, y) = x - y = 0 \) if and only if \( x = y \), property 2 is satisfied. Because \( d(2, 1) = 1 \), it follows that \( d(1, 2) \neq d(2, 1) \) and so the symmetric property (property 3) is not satisfied. Finally,

\[
d(x, z) = x - z = (x - y) + (y - z) = d(x, y) + d(y, z),
\]

and the triangle inequality (property 4) holds.

In our next example, we present a distance function that is actually a metric on \( \mathbb{R} \).

**Result 19.2**  For \( X = \mathbb{R} \), let \( d : X \times X \to \mathbb{R} \) be defined by

\[
d(x, y) = |2^x - 2^y|.
\]

Then \( (X, d) \) is a metric space.

**Proof**  Clearly, \( d(x, y) = |2^x - 2^y| \geq 0 \) and \( d(x, y) = 0 \) if and only if \( 2^x = 2^y \). Certainly, if \( x = y \), then \( 2^x = 2^y \). Since the function \( f : \mathbb{R} \to \mathbb{R} \) defined by \( f(x) = 2^x \) is one-to-one, it follows that if \( 2^x = 2^y \), then \( x = y \). Thus, \( d(x, y) = 0 \) if and only if \( x = y \). Since \( d(x, y) = |2^x - 2^y| = |2^y - 2^x| = d(y, x) \), it follows that \( d \) satisfies the symmetric property. Finally, by property 4 in (19.1),

\[
d(x, z) = |2^x - 2^z| = |(2^x - 2^y) + (2^y - 2^z)| \leq |2^x - 2^y| + |2^y - 2^z| = d(x, y) + d(y, z)
\]

and the triangle inequality holds.

Another set on which you have undoubtedly seen a distance defined is \( \mathbb{R} \times \mathbb{R} = \mathbb{R}^2 \). Hence, an element \( P \in \mathbb{R}^2 \) can be expressed as \((x, y)\), where \( x, y \in \mathbb{R} \). Here we are discussing points in the Cartesian plane, as you saw in the study of analytic geometry. In the Cartesian plane, the (Euclidean) distance \( d(P_1, P_2) \) between two points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) is given by

\[
d(P_1, P_2) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}.
\]
19.1 Metric Spaces

This distance is actually a metric on \( \mathbb{R}^2 \). That the first three properties are satisfied depends only on the following facts for real numbers \( a \) and \( b \): (1) \( a^2 \geq 0 \), (2) \( a^2 + b^2 = 0 \) if and only if \( a = b = 0 \), (3) \( a^2 = (-a)^2 \). The triangle inequality is more difficult to verify, however, and its proof depends on the following lemma, which is a special case of a result commonly called **Schwarz’s Inequality**.

**Lemma 19.3** If \( a, b, c, d \in \mathbb{R} \), then

\[
ab + cd \leq \sqrt{(a^2 + c^2)(b^2 + d^2)}.
\]

**Proof** Certainly, \( (ab + cd)^2 + (ad - bc)^2 \geq (ab + cd)^2 \). Since

\[
(ab + cd)^2 + (ad - bc)^2 = (a^2b^2 + 2abcd + c^2d^2) + (a^2d^2 - 2abcd + b^2c^2) = a^2b^2 + a^2d^2 + b^2c^2 + c^2d^2 = (a^2 + c^2)(b^2 + d^2),
\]

the desired inequality follows. \( \blacksquare \)

We can now show that this distance is a metric.

**Result 19.4** For \( X = \mathbb{R}^2 \), let \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) be two points in \( \mathbb{R}^2 \) and let \( d : X \times X \to \mathbb{R} \) be defined by

\[
d(P_1, P_2) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}.
\]

Then \( (X, d) \) is a metric space.

**Proof** We have already mentioned that the first three properties of a metric are satisfied, so only the triangle inequality remains to be verified. Let \( P_1 = (x_1, y_1), P_2 = (x_2, y_2) \) and \( P_3 = (x_3, y_3) \). Thus, using Lemma 19.3, where \( a = x_1 - x_2, b = x_2 - x_3, c = y_1 - y_2 \) and \( d = y_2 - y_3 \), we have

\[
[d(P_1, P_3)]^2 = (x_1 - x_3)^2 + (y_1 - y_3)^2
= [(x_1 - x_2) + (x_2 - x_3)]^2 + [(y_1 - y_2) + (y_2 - y_3)]^2
= (x_1 - x_2)^2 + (x_2 - x_3)^2 + 2(x_1 - x_2)(x_2 - x_3) + 2(y_1 - y_2)(y_2 - y_3) + (y_1 - y_2)^2 + (y_2 - y_3)^2
\leq (x_1 - x_2)^2 + (x_2 - x_3)^2 + 2\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}(x_2 - x_3)^2 + (y_2 - y_3)^2
= (\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2} + \sqrt{(x_2 - x_3)^2 + (y_2 - y_3)^2})^2
= [d(P_1, P_2) + d(P_2, P_3)]^2,
\]

which gives us the desired result. \( \blacksquare \)

There is a metric defined on \( \mathbb{N} \times \mathbb{N} = \mathbb{N}^2 \) which goes by the name of the **Manhattan metric** or **taxicab metric**. For points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) in \( \mathbb{N}^2 \), the distance
4 Chapter 19 Proofs in Topology

\( d(P_1, P_2) \) is defined by

\[
d(P_1, P_2) = |x_1 - x_2| + |y_1 - y_2|.
\]

For example, consider the points \( P_1 = (2, 2) \) and \( P_2 = (4, 6) \) shown in Figure 19.1 (a). The taxicab distance between these two points is \( d(P_1, P_2) = |2 - 4| + |2 - 6| = 6 \). Thinking of the points \((x, y)\) as street intersections in a certain city (Manhattan), we have a minimum of 6 blocks to travel (by taxicab). Two such routes are shown in Figure 19.1 (b), (c).

![Figure 19.1 The Manhattan metric](image)

Not only is the Manhattan metric a metric on \( \mathbb{N}^2 \), it is also a metric on \( \mathbb{Z}^2 \) and on \( \mathbb{R}^2 \). A proof of the following result is left as an exercise (Exercise 19.2).

**Result 19.5** For points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) in \( \mathbb{R}^2 \), the distance \( d(P_1, P_2) \) defined by

\[
d(P_1, P_2) = |x_1 - x_2| + |y_1 - y_2|
\]

is a metric on \( \mathbb{R}^2 \) (the Manhattan metric).

We have seen that there is more than one metric on both \( \mathbb{R} \) and \( \mathbb{R}^2 \). The metric spaces \((\mathbb{R}, d)\), where \( d(x, y) = |x - y| \), and \((\mathbb{R}^2, d)\), where

\[
d((x_1, y_1), (x_2, y_2)) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2},
\]

are called **Euclidean spaces** and the associated metrics are the **Euclidean metrics**. These are certainly the most familiar metrics on \( \mathbb{R} \) and \( \mathbb{R}^2 \).

For every nonempty set \( A \), it is always possible to define a distance \( d : A \times A \to \mathbb{R} \) that is a metric.

**Result 19.6** Let \( A \) be a nonempty set. For \( x, y \in A \), the distance \( d(x, y) \) defined by

\[
d(x, y) = \begin{cases} 
0 & \text{if } x = y \\
1 & \text{if } x \neq y
\end{cases}
\]

is a metric on \( A \).
By definition, \( d(x, y) \geq 0 \) for all \( x, y \in A \) and \( d(x, y) = 0 \) if and only if \( x = y \). Also, by the definition of this distance, \( d(x, y) = d(y, x) \) for all \( x, y \in A \). Now let \( x, y, z \in A \). If \( x = z \), then certainly \( 0 = d(x, z) \leq d(x, y) + d(y, z) \). If \( x \neq z \), then \( d(x, z) = 1 \). Since \( x \neq y \) or \( y \neq z \), it follows that \( d(x, y) + d(y, z) \geq 1 = d(x, z) \). In any case, the triangle inequality holds.

For a nonempty set \( A \), the distance \( d \) defined on \( A \) as described in Result 19.6 is called the **discrete metric** on \( A \).

19.2 OPEN SETS IN METRIC SPACES

Returning to our discussion of real-valued functions \( f \) from calculus, we said that \( f \) is continuous at a real number \( a \) in the domain of \( f \) if for every \( \epsilon > 0 \), there exists a number \( \delta > 0 \) such that if \( |x - a| < \delta \), then \( |f(x) - f(a)| < \epsilon \). This, of course, is what led us to rethink what we meant by distance and which then led us to metric spaces. However, continuity itself can be described in a somewhat different manner. A function \( f \) is continuous at \( a \) if for every \( \epsilon > 0 \), there exists a number \( \delta > 0 \) such that if \( x \) is a number in the open interval \((a - \delta, a + \delta)\), then \( f(x) \) is a number in the open interval \((f(a) - \epsilon, f(a) + \epsilon)\). That is, continuity can be defined in terms of open intervals. What are some properties of open intervals? Of course, an open interval is a certain kind of subset of the set of real numbers. But each open interval has a property that can be generalized in a very useful manner. An open interval \( I \) of real numbers has the property that for every \( x \in I \), there exists a real number \( r > 0 \) such that \((x - r, x + r) \subseteq I \), that is, for every \( x \in I \), there is an open interval \( I_x \) centered at \( x \) that is contained in \( I \).

Let \((X, d)\) be a metric space. Also, let \( a \in X \) and let a real number \( r > 0 \) be given. The subset of \( X \) consisting of those points (elements) \( x \in X \) such that \( d(x, a) < r \) is called the open sphere with center \( a \) and radius \( r \) and is denoted by \( S_r(a) \). Thus, \( x \in S_r(a) \) if and only if \( d(x, a) < r \). For example, the open sphere \( S_r(a) \) in the Euclidean space \((\mathbb{R}, d)\) is the open interval \((a - r, a + r)\) with mid-point \( a \) and length \( 2r \). Conversely, each open interval in \((\mathbb{R}, d)\) is an open sphere according to this definition. So, the open spheres in \((\mathbb{R}, d)\) are precisely the open intervals of the form \((a, b)\), where \( a, b \in \mathbb{R} \) and \( a < b \). In the Euclidean space \((\mathbb{R}^2, d)\), the open sphere \( S_r(P) \) is the interior of the circle with center \( P \) and radius \( r \). In the Manhattan metric space \((\mathbb{R}^2, d)\), where the distance between two points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) is defined by \( d(P_1, P_2) = |x_1 - x_2| + |y_1 - y_2| \), the open sphere \( S_3(P) \) for \( P = (5, 4) \) is the interior of the square shown in Figure 19.2.

Since every point in a metric space \((X, d)\) belongs to an open sphere in \( X \) (indeed, it is the center of an open sphere), it is immediate that every two distinct points of \( X \) belong to distinct open spheres. In fact, they belong to disjoint open spheres.

**Theorem 19.7** Every two distinct points in a metric space belong to disjoint open spheres.

**Proof** Let \( a \) and \( b \) be distinct points in a metric space \((X, d)\) and suppose that \( d(a, b) = r \). Necessarily, \( r > 0 \). Consider the open spheres \( S_{r/2}(a) \) and \( S_{r/2}(b) \) having radius \( r/2 \) centered at \( a \) and \( b \), respectively. We claim that \( S_{r/2}(a) \cap S_{r/2}(b) = \emptyset \). Assume, to the contrary,
6 Chapter 19 Proofs in Topology

A subset $O$ of a metric space $(X, d)$ is defined to be **open** in $(X, d)$ if for every point $a$ of $O$, there exists a positive real number $r$ such that $S_r(a) \subseteq O$, that is, each point of $O$ is the center of an open sphere contained in $O$. In the Euclidean space $(\mathbb{R}, d)$, each open interval $(a, b)$, where $a < b$, is an open set. To see this, for each $x \in (a, b)$, let $r = \min(x - a, b - x)$. Then the open sphere $S_r(x) = (x - r, x + r)$ is contained in $(a, b)$. In fact, the set $(-\infty, a) \cup (a, \infty)$ is open in $(\mathbb{R}, d)$ for each $a \in \mathbb{R}$. On the other hand, the half-open interval (or half-closed interval) $(a, b]$ is not open since there exists no open sphere centered at $b$ and contained in $(a, b]$. Similarly, the sets $[a, b], [a, b), (-\infty, a]$ and $[a, \infty)$ are also not open in $(\mathbb{R}, d)$.

Every metric space contains some open sets, as we now show.

**Theorem to Prove**

In a metric space $(X, d)$,

(i) the empty set $\emptyset$ and the set $X$ are open, and  
(ii) every open sphere is an open set.

**PROOF STRATEGY**

To show that a subset $A$ of $X$ is open, it is required to show that if $a$ is a point of $A$, then $a$ is the center of an open sphere contained in $A$. The empty set satisfies this condition vacuously and $X$ satisfies this condition trivially, so we concentrate on verifying (ii).

We begin with an open sphere $S_r(a)$ having center $a$ and radius $r$. For an arbitrary element $x \in S_r(a)$, we need to show that there is an open sphere centered at $x$ and with an appropriate radius that is contained in $S_r(a)$. Since the theorem concerns an arbitrary metric space $(X, d)$, there is not necessarily any geometric appearance to the open sphere $S_r(a)$. On the other hand, it is helpful to visualize $S_r(a)$ as the interior of a circle (see Figure 19.3).
Open Sets in Metric Spaces

Theorem 19.8 In a metric space \((X, d)\),

(i) the empty set \(\emptyset\) and the set \(X\) are open, and
(ii) every open sphere is an open set.

Proof Since there is no point in \(\emptyset\), the statement that \(\emptyset\) is open is true vacuously. For each point \(a \in X\), every open sphere centered at \(a\) is contained in \(X\). Thus, \(X\) is open and (i) is verified.

To verify (ii), let \(S_r(a)\) be an open sphere in \((X, d)\) and let \(x \in S_r(a)\). We show that there exists an open sphere centered at \(x\) and contained in \(S_r(a)\). Since \(d(x, a) < r\), it follows that \(r' = r - d(x, a) > 0\). We show that \(S_{r'}(x) \subseteq S_r(a)\). Let \(y \in S_{r'}(x)\). Since \(d(y, x) < r'\) and \(d(x, a) = r - r'\), it follows by the triangle inequality that

\[
d(y, a) = d(y, x) + d(x, a) < r' + (r - r') = r.
\]

Therefore, \(y \in S_r(a)\) and so \(S_{r'}(x) \subseteq S_r(a)\).

To illustrate Theorem 19.8, we turn to the metric space \((X, d)\) described in Result 19.2, namely, \(X = \mathbb{R}\) with \(d(x, y) = |2^x - 2^y|\) for \(x, y \in \mathbb{R}\). Thus, \(\emptyset\) and \(X = \mathbb{R}\) are open sets as are all open spheres \(S_r(a)\), where \(a \in \mathbb{R}\) and \(r > 0\). One such open sphere is \(S_1(0) = \{x \in \mathbb{R} : |2^x - 2^0| < 1\}\). The inequality \(|2^1 - 2^0| < 1\) is equivalent to the inequalities \(-1 < 2^x - 1 < 1\) and \(0 < 2^x < 2\). Since \(2^x > 0\) for all \(x\), it follows that \(0 < 2^x < 2\) is satisfied for all real numbers in the infinite interval \((-\infty, 1)\), and so \((-\infty, 1)\) is the open sphere with center 0 and radius 1 (according to the given metric).

We also consider the open sphere \(S_6(1) = \{x \in \mathbb{R} : |2^x - 2^1| < 6\}\). Here, \(|2^x - 2^1| < 6\) is equivalent to the inequalities \(-6 < 2^x - 2 < 6\) and \(-4 < 2^x < 8\) and so \(S_6(1)\) is the open sphere \((-\infty, 3)\) with center 1 and radius 6.

We are now prepared to present a characterization of open sets in any metric space.

Theorem 19.9 A subset \(O\) of a metric space is open if and only if it is a (finite or infinite) union of open spheres.

Proof Let \((X, d)\) be a metric space. First let \(O\) be an open set in \((X, d)\). We show that \(O\)
is a union of open spheres. If \( O = \emptyset \), then \( O \) is the union of zero open spheres. So, we may assume that \( O \neq \emptyset \). Let \( x \in O \). Since \( O \) is open, there exists a positive number \( r_x \) such that \( S_x(x) \subseteq O \). This implies that \( \bigcup_{x \in O} S_x(x) \subseteq O \). On the other hand, if \( x \in O \), then \( x \in S_x(x) \subseteq \bigcup_{x \in O} S_x(x) \), implying that \( O \subseteq \bigcup_{x \in O} S_x(x) \). Therefore, \( O = \bigcup_{x \in O} S_x(x) \).

Next we show that if \( O \) is a subset of \((X, d)\) that is a union of open spheres, then \( O \) is open. If \( O = \emptyset \), then \( O \) is open. Hence, we may assume that \( O \neq \emptyset \). Let \( x \in O \). Since \( O \) is a union of open spheres, \( x \) belongs to some open sphere, say \( S_x(a) \). Since \( S_x(a) \) is open, there exists \( r' > 0 \) (as we saw in the proof of Theorem 19.8) such that \( S_x(x) \subseteq S_x(a) \subseteq O \). Therefore, \( O \) is open. \[ \square \]

Two important properties of open sets are established in the next theorem.

**Theorem 19.10** Let \((X, d)\) be a metric space. Then

(i) the intersection of any finite number of open sets in \( X \) is open, and

(ii) the union of any number of open sets in \( X \) is open.

**Proof** We first verify (i). Let \( O_1, O_2, \ldots, O_k \) be \( k \) open sets in \( X \), and let \( O = \bigcap_{i=1}^{k} O_i \). If \( O \) is empty, then \( O \) is open by Theorem 19.8(i). Thus, we may assume that \( O \) is nonempty and let \( x \in O \). We show that \( x \) is the center of an open sphere that is contained in \( O \). Since \( x \in O \), it follows that \( x \in O_i \) for all \( i (1 \leq i \leq k) \). Because each set \( O_i \) is open, there exists an open sphere \( S_x(x) \subseteq O_i \), where \( 1 \leq i \leq k \). Let \( r = \min\{r_1, r_2, \ldots, r_k\} \). Then \( r > 0 \) and \( S_x(x) \subseteq S_x(x) \subseteq O_i \) for each \( i (1 \leq i \leq k) \). Therefore, \( S_x(x) \subseteq \bigcap_{i=1}^{k} O_i = O \). Thus, \( O \) is open.

Next we verify (ii). Let \( \{O_a\}_{a \in I} \) be an indexed collection of open sets in \( X \) and let \( O = \bigcup_{a \in I} O_a \). We show that \( O \) is open. If \( O = \emptyset \), then again \( O \) is open. So, we assume that \( O \neq \emptyset \). By Theorem 19.9, each open set \( O_a (a \in I) \) is the union of open spheres. Thus, \( O \) is a union of open spheres. It again follows by Theorem 19.9 that \( O \) is open. \[ \square \]

For the Euclidean space \((\mathbb{R}, d)\), each open interval \( I_n = \left(-1 - \frac{1}{n}, 1 + \frac{1}{n}\right) \), \( n \in \mathbb{N} \), is an open set. By Theorem 19.10, \( \bigcup_{n=1}^{\infty} I_n = (-2, 2) \) is an open set, as is \( \bigcap_{n=1}^{100} I_n = \left(-\frac{101}{100}, \frac{101}{100}\right) \). However, Theorem 19.10 does not guarantee that \( \bigcap_{n=1}^{\infty} I_n \) is open. Indeed, \( \bigcap_{n=1}^{\infty} I_n \) is the closed interval \([-1, 1]\), which is not an open set. The open interval \( J_n = \left(0, \frac{1}{n}\right) \), \( n \in \mathbb{N} \), is an open set as well. Thus, \( \bigcup_{n=1}^{\infty} J_n = (0, 1) \) is an open set. In this case, \( \bigcap_{n=1}^{\infty} J_n = \emptyset \), which is also an open set.

We now turn to the Euclidean space \((\mathbb{R}^2, d)\). Let \( P_0 = (0, 0) \). For \( n \in \mathbb{N} \), the open...
sphere \( S_n(P_0) \) centered at \((0, 0)\) and having radius \(n\) is an open set. Here, \( \bigcup_{n=1}^{\infty} S_n(P_0) = \mathbb{R}^2 \), which is open, while \( \bigcap_{n=1}^{\infty} S_n(P_0) = S_1(P_0) \), which is open. In \((\mathbb{R}^2, d)\), where \(d\) is the discrete metric, \(S_1(P_0) = \{P_0\}\), while \(S_2(P_0) = \mathbb{R}^2 \). Of course, all sets are open in a discrete metric space.

There is another important class of sets in metric spaces that arise naturally from open sets. Let \((X, d)\) be a metric space. A subset \(F\) of \(X\) is called closed if its complement \(\overline{F}\) is open. For example, in the Euclidean space \((\mathbb{R}, d)\), each closed interval \([a, b]\) where \(a < b\), is closed since its complement \((-\infty, a) \cup (b, \infty)\) is open. Let \(a\) be a point in a metric space and let \(S[a]\) consist of those points \(x \in X\) such that \(d(x, a) \leq r\). The set \(S[a]\) is called a closed sphere with center \(a\) and radius \(r\). Not surprisingly, \(S[a]\) is closed, as we show next. Moreover, \(\emptyset\) and \(X\) are both open and closed.

**Theorem 19.11** In a metric space \((X, d)\),

(i) \(\emptyset\) and \(X\) are closed, and

(ii) every closed sphere is closed.

**Proof** Since \(\emptyset\) and \(X\) are complements of each other and each is open, it follows that each is closed. To verify (ii), let \(S[a]\) be a closed sphere in \((X, d)\), where \(a \in X\). We show that its complement \(\overline{S[a]}\) is open. We may assume that \(\overline{S[a]}\) is nonempty and a proper subset of \(X\). Let \(x \in \overline{S[a]}\). Thus, \(d(x, a) > r\) and \(r^* = d(x, a) - r > 0\). We show that \(S^*(x) \subseteq \overline{S[a]}\), that is, if \(y \in S^*(x)\), then \(y \notin S[a]\). Let \(y \in S^*(x)\). Since \(d(x, y) < r^* = d(x, a) - r\), it then follows by the triangle inequality that

\[
d(y, a) \geq d(x, a) - d(x, y) > d(x, a) - r^* = r
\]

and so \(d(y, a) > r\). Hence, \(y \in \overline{S[a]}\), which implies that \(S^*(x) \subseteq \overline{S[a]}\). \(\square\)

Some other useful facts about closed sets follow immediately from Theorem 19.10. First, it is useful to recall from Theorem 6.15 and Exercise 6.29 that if \(A_1, A_2, \ldots, A_n\) are \(n \geq 2\) sets, then

\[
\bigcup_{i=1}^{n} A_i = \bigcap_{i=1}^{n} \overline{A}_i \quad \text{and} \quad \bigcap_{i=1}^{n} A_i = \bigcup_{i=1}^{n} \overline{A}_i.
\]

These are De Morgan’s Laws for any finite number of sets. There is a more general form of De Morgan’s Laws.

**Theorem 19.12** (Extended De Morgan’s Laws) For an indexed collection \(\{A_a\}_{a \in I}\) of sets,

\[
(a) \quad \bigcup_{a \in I} \overline{A}_a = \bigcap_{a \in I} \overline{A}_a \quad \text{and} \quad (b) \quad \bigcap_{a \in I} \overline{A}_a = \bigcup_{a \in I} \overline{A}_a.
\]

We present the proof of (a) only, leaving the proof of (b) as an exercise (Exercise 19.14).
Chapter 19  Proofs in Topology

Proof of Theorem 19.12 (a)

First we show that \( \bigcup_{\alpha \in I} A_\alpha \subseteq \bigcap_{\alpha \in I} A_\alpha \). Let \( x \in \bigcup_{\alpha \in I} A_\alpha \). Then \( x \notin \bigcup_{\alpha \notin I} A_\alpha \). Hence, \( x \notin A_\alpha \) for each \( \alpha \in I \), which implies that \( x \in \overline{A_\alpha} \) for all \( \alpha \in I \). Consequently, \( x \in \bigcap_{\alpha \in I} \overline{A_\alpha} \) and so \( \bigcup_{\alpha \in I} A_\alpha \subseteq \bigcap_{\alpha \in I} \overline{A_\alpha} \).

Next we show that \( \bigcap_{\alpha \in I} A_\alpha \subseteq \bigcup_{\alpha \in I} A_\alpha \). Let \( x \in \bigcap_{\alpha \in I} A_\alpha \). Then \( x \in \overline{A_\alpha} \) for each \( \alpha \in I \).

Thus, \( x \notin \overline{A_\alpha} \) for all \( \alpha \in I \). This implies, however, that \( x \notin \bigcup_{\alpha \in I} A_\alpha \) and, hence, that \( x \in \bigcup_{\alpha \in I} A_\alpha \). Therefore, \( \bigcap_{\alpha \in I} A_\alpha \subseteq \bigcup_{\alpha \in I} A_\alpha \). \( \blacksquare \)

Corollary 19.13 Let \( (X, d) \) be a metric space. Then

(i) the union of any finite collection of closed sets in \( X \) is closed, and
(ii) the intersection of any collection of closed sets in \( X \) is closed.

Proof Let \( F_1, F_2, \ldots, F_k \) be \( k \) closed sets in \( X \) and let \( F = \bigcup_{i=1}^{k} F_i \). Then \( \overline{F} = \bigcap_{i=1}^{k} \overline{F_i} \).

Since each set \( F_i \) (\( 1 \leq i \leq k \)) is closed, each set \( \overline{F_i} \) is open. By Theorem 19.10, \( \overline{F} \) is open and so \( F \) is closed. This verifies (i).

Next we verify (ii). Let \( \{F_\alpha\}_{\alpha \in I} \) be an indexed collection of closed sets in \( X \), and let \( F = \bigcap_{\alpha \in I} F_\alpha \). Then \( \overline{F} = \bigcap_{\alpha \in I} \overline{F_\alpha} = \bigcup_{\alpha \in I} \overline{F_\alpha} \) by Theorem 19.12. Since each set \( F_\alpha \) (\( \alpha \in I \)) is closed, each set \( \overline{F_\alpha} \) is open. By Theorem 19.10, \( \overline{F} \) is open and so \( F \) is closed. \( \blacksquare \)

19.3 CONTINUITY IN METRIC SPACES

In calculus, we saw that defining a function \( f \) to be continuous at a real number can be formulated in terms of distance or in terms of open intervals, each of which can be generalized. Now we generalize the concept of continuity itself.

Let \( (X, d) \) and \( (Y, d') \) be metric spaces, and let \( a \in X \). A function \( f : X \to Y \) is said to be **continuous at the point** \( a \) if for every positive real number \( \epsilon \), there exists a positive real number \( \delta \) such that if \( x \in X \) and \( d(x, a) < \delta \), then \( d'(f(x), f(a)) < \epsilon \). The function \( f : X \to Y \) is **continuous** on \( X \) if it is continuous at each point of \( X \). If \( X = Y = \mathbb{R} \) and \( d = d' \) is defined by \( d(x, y) = |x - y| \) for all \( x, y \in \mathbb{R} \), then we are giving the standard definition of continuity in calculus.

We now consider some examples of continuous functions in this more general setting.

Result 19.14 Let \( (\mathbb{R}^2, d) \) be the Manhattan metric space whose distance \( d(P_1, P_2) \) between two points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) in \( \mathbb{R}^2 \) is defined by \( d(P_1, P_2) = |x_1 - x_2| + |y_1 - y_2| \), and let \( (\mathbb{R}, d') \) be the Euclidean space, where \( d'(a, b) = |a - b| \). Then
19.3 Continuity in Metric Spaces

(i) the function \( f : \mathbb{R}^2 \to \mathbb{R} \) defined by \( f((x, y)) = f(x, y) = x + y \) is continuous.

(ii) the function \( g : \mathbb{R}^2 \to \mathbb{R} \) defined by \( g(x, y) = d'(x, y) = |x - y| \) is continuous.

**Proof** We first verify (i). Let \( \epsilon > 0 \) be given and let \( P_0 = (x_0, y_0) \in \mathbb{R}^2 \). We choose \( \delta = \epsilon \). Now let \( P = (x, y) \in \mathbb{R}^2 \) such that \( d(P, P_0) = |x - x_0| + |y - y_0| < \delta \). Then

\[
|f'(x, y), f(x_0, y_0)| = d'(x + y, x_0 + y_0) = |x + y - (x_0 + y_0)| = |(x - x_0) + (y - y_0)| \leq |x - x_0| + |y - y_0| < \delta = \epsilon.
\]

Therefore, \( f \) is continuous.

We now verify (ii). Again, let \( \epsilon > 0 \) be given and let \( P_0 = (x_0, y_0) \in \mathbb{R}^2 \). For a given \( \epsilon > 0 \), choose \( \delta = \epsilon \). Let \( P = (x, y) \in \mathbb{R}^2 \) such that \( d(P, P_0) = |x - x_0| + |y - y_0| < \delta \). We show that

\[
d'(g(P), g(P_0)) = d'(|x - y|, |x_0 - y_0|) = ||x - y| - |x_0 - y_0|| < \epsilon,
\]

which is equivalent to \(-\epsilon < |x - y| - |x_0 - y_0| < \epsilon\). Observe, by the triangle inequality, that

\[
|x - y| - |x_0 - y_0| = |(x - x_0) + (x_0 - y_0) + (y_0 - y)| - |x_0 - y_0|
\]

\[
\leq |x - x_0| + |x_0 - y_0| + |y_0 - y| - |x_0 - y_0|
\]

\[
= |x - x_0| + |y_0 - y| < \delta = \epsilon.
\]

Similarly,

\[
|x_0 - y_0| - |x - y| \leq |x - x_0| + |x - y| + |y_0 - y| - |x - y| = |x - x_0| + |y_0 - y| < \epsilon.
\]

**PROOF ANALYSIS** Let's review how Theorem 19.14(ii) was proved. The main goal was to show that \(|x - y| - |x_0 - y_0| < \epsilon\) given that \(|x - x_0| + |y_0 - y| < \delta\). Letting \( a = |x - y| \) and \( b = |x_0 - y_0| \), we have the inequality \( |a - b| < \epsilon \) to verify, which is equivalent to \(-\epsilon < a - b < \epsilon\), which, in turn, is equivalent to

\[
a - b < \epsilon \text{ and } b - a < \epsilon.
\]

Thus, one of the inequalities we wish to establish is \(|x - y| - |x_0 - y_0| < \epsilon\). Since we know that \(|x - x_0| + |y_0 - y| < \delta\), this suggests working the expression \(|x - x_0| + |y_0 - y|\) into the expression \(|x - y| - |x_0 - y_0|\). This can be accomplished by adding and subtracting the appropriate quantities. Observe that

\[
|x - y| - |x_0 - y_0| = |(x - x_0) + (x_0 - y_0) + (y_0 - y)| - |x_0 - y_0|
\]

\[
\leq |x - x_0| + |x_0 - y_0| + |y_0 - y| - |x_0 - y_0|
\]

\[
= |x - x_0| + |y_0 - y| < \delta.
\]

This suggests choosing \( \delta = \epsilon \). Of course, we must be certain that with this choice of \( \delta \), we can also show that \(|x_0 - y_0| - |x - y| < \epsilon\).

The function \( i : \mathbb{R} \to \mathbb{R} \) defined by \( i(x) = x \) for all \( x \in \mathbb{R} \) is, of course, the identity function. It would probably seem that this function must surely be continuous. However, this depends on the metric being used.
Example 19.15 Let (R, d) be the discrete metric space and (R, d’) the Euclidean space with d’(x, y) = |x − y| for all x, y ∈ R. Then

(i) the function f : (R, d) → (R, d’) defined by f(x) = x for all x ∈ R is continuous, and

(ii) the function g : (R, d) → (R, d) defined by g(x) = x for all x ∈ R is not continuous.

Solution First we verify (i). Let a ∈ R and let ϵ > 0 be given. Choose δ = 1/2. Let x ∈ R such that d(x, a) < δ = 1/2. We show that d’(f(x), f(a)) < ϵ. Since d is the discrete metric and d(x, a) < 1/2, it follows that x = a. Hence, d’(f(x), f(a)) = |f(x) − f(a)| = |x − a| = |a − a| = 0 < ϵ.

Next we verify (ii). Let a ∈ R and choose ϵ = 1/2. Let δ be any positive real number. Let x = a + δ/2 ∈ R. Then d’(x, a) = |x − a| = |(a + δ/2) − a| = δ/2 < δ. Since x ≠ a, d(g(x), g(a)) = d(x, a) = 1 > ϵ. Hence, for ϵ = 1/2, there is no δ > 0 such that if d’(x, δ) < δ, then d(g(x), g(a)) < ϵ. Therefore, g is not continuous at a.

Continuity of functions defined from one metric space to another can also be described by means of open sets. To do this, we need additional definitions and notation.

Let (X, d) and (Y, d’) be metric spaces and let f : X → Y. If A is a subset of X, then its image f(A) is that subset of Y defined by

\[ f(A) = \{ f(x) : x \in A \}. \]

Similarly, if B is a subset of Y, then its inverse image \( f^{-1}(B) \) is defined by

\[ f^{-1}(B) = \{ x \in X : f(x) \in B \}. \]

To illustrate these concepts, consider a function f : R → R for some metric d on R, where f is defined by f(x) = x^2 for all x ∈ R. Then f(x) is a polynomial (whose graph is a parabola). Let A = (−1, 2], B = [−2, 2] and C = [0, 4]. Then f(A) = C, while f^{-1}(C) = B.

Next let (X, d) and (Y, d’) be metric spaces, let f : X → Y and let a ∈ X. Suppose that for each ϵ > 0, there exists δ > 0 such that if x ∈ X and d(x, a) < δ, then d’(f(x), f(a)) < ϵ. Then f is continuous at a. Equivalently, f is continuous at a if whenever x ∈ S_δ(a), then f(x) ∈ S_ε(f(a)). Hence, f is continuous at a if for each ϵ > 0, there exists δ > 0 such that f(S_δ(a)) ⊆ S_ε(f(a)). We now present a characterization of those functions f that are continuous on the entire set X.

Theorem to Prove Let (X, d) and (Y, d’) be metric spaces and let f : X → Y. Then f is continuous on X if and only if for each open set O in Y, the inverse image f^{-1}(O) is an open set in X.

Proof Strategy Let’s begin with the implication: If f is continuous on X, then for each open set O in Y, the inverse image f^{-1}(O) is an open set in X. Using a direct proof, we would begin by assuming that f is continuous and that O is an open set in Y. If f^{-1}(O) = ∅, then f^{-1}(O) is an open set in X; while if f^{-1}(O) ≠ ∅, then we are required to show that every element x ∈ f^{-1}(O) is the center of an open sphere contained in f^{-1}(O). So, let x ∈ f^{-1}(O). Therefore, f(x) ∈ O. We know that O is open, so there is some open sphere
Let \( (X, d) \) and \((Y, d')\) be metric spaces and let \( f : X \to Y \). Then \( f \) is continuous on \( X \) if and only if for each open set \( O \) in \( Y \), the inverse image \( f^{-1}(O) \) is an open set in \( X \).

**Proof**
Assume first that \( f \) is continuous on \( X \). Let \( O \) be an open set in \( Y \). We show that \( f^{-1}(O) \) is open in \( X \). If \( f^{-1}(O) = \emptyset \), then \( f^{-1}(O) \) is open, so we may assume that \( f^{-1}(O) \neq \emptyset \). Let \( x \in f^{-1}(O) \). Since \( x \in f^{-1}(O) \), it follows that \( f(x) \in O \). Because \( O \) is open, there exists an open sphere \( S_x(f(x)) \) that is contained in \( O \). Since \( f \) is continuous at \( x \), there exists \( \delta > 0 \) such that \( f(S_x(x)) \subseteq S_x(f(x)) \subseteq O \). Thus, \( S_x(x) \subseteq f^{-1}(O) \) and, hence, \( f^{-1}(O) \) is open, as desired.

For the converse, assume that for each open set \( O \) of \( Y \), the inverse image \( f^{-1}(O) \) is an open set of \( X \). We show that \( f \) is continuous on \( X \). Let \( a \) be an arbitrary point in \( X \). Let \( \epsilon > 0 \) be given. The set \( S_a(f(a)) \) is open in \( Y \) and so its inverse image \( f^{-1}(S_a(f(a))) \) is open in \( X \) and contains \( a \). Then there exists \( \delta > 0 \) such that the open sphere \( S_x(f(a)) \subseteq f^{-1}(S_a(f(a))) \). Therefore, \( f(S_a(a)) \subseteq S_x(f(a)) \) and so \( f \) is continuous at \( a \). Hence, \( f \) is continuous on \( X \).

With the aid of Theorem 19.16, it can now be shown that any constant function from one metric space to another is continuous.

**Result 19.17**
Let \( (X, d) \) and \((Y, d')\) be metric spaces and let \( f : X \to Y \) be a constant function, that is, \( f(x) = c \) for some fixed element \( c \in Y \) for all \( x \in X \). Then \( f \) is continuous.

**Proof**
Let \( O \) be an open set in \( Y \). Then \( f^{-1}(O) = \emptyset \) if \( c \notin O \); otherwise \( f^{-1}(O) = X \). In any case, \( f^{-1}(O) \) is open. By Theorem 19.16, \( f \) is continuous on \( X \).

### 19.4 TOPOLOGICAL SPACES

In the previous section, we introduced the concept of a continuous function from one metric space to another, and the definition was formulated in terms of the metrics on the spaces involved. However, Theorem 19.16 shows that the continuity of a function on a metric space can be established in terms of open sets only, without any direct reference to metrics. This suggests the possibility of discarding metrics altogether, replacing them by open sets, and describing continuity in an even more general setting. This gives rise to another mathematical structure, called a topological space.
14 Chapter 19 Proofs in Topology

Let \( X \) be a nonempty set and let \( \tau \) (the Greek letter “tau”) be a collection of subsets of \( X \). Then \( (X, \tau) \) is called a topological space and \( \tau \) itself is called a topology on \( X \) if the following properties are satisfied:

1. \( X \in \tau \) and \( \emptyset \in \tau \).
2. If \( O_1, O_2, \ldots, O_n \in \tau \), then \( \bigcap_{i=1}^n O_i \in \tau \).
3. If, for an index set \( I \), \( O_\alpha \in \tau \) for each \( \alpha \in I \), then \( \bigcup_{\alpha \in I} O_\alpha \in \tau \).

In a topological space \( (X, \tau) \), we refer to each element of \( \tau \) as an open set of \( X \). Property (1) states that \( X \) and the empty set are open. Property (2) states that the intersection of any finite collection of open sets is open, while property (3) states the union of any collection of open sets is open. For example, for a nonempty set \( X \), let \( \tau_1 = \{ \emptyset, X \} \) and \( \tau_2 = \mathcal{P}(X) \), the set of all subsets of \( X \). Then \( (X, \tau_1) \) and \( (X, \tau_2) \) are topological spaces. The topology \( \tau_1 \) is called the trivial topology on \( X \), while \( \tau_2 \) is the discrete topology on \( X \). In \( (X, \tau_1) \), the only open sets are \( X \) and \( \emptyset \); while in \( (X, \tau_2) \), every subset of \( X \) is open.

It follows immediately from the definition of a topological space and the properties of open sets in a metric space that every metric space is a topological space. The converse is not true, however. When we say that a topological space \( (X, \tau) \) is a metric space, we mean that it is possible to define a metric \( d \) on \( X \) such that the set of open sets of \( (X, d) \) is \( \tau \).

Example 19.18 Let \( X = \{a, b, c\} \) and \( \tau = \{\emptyset, X, \{a\}, \{a, b\}, \{a, c\}\} \). Then \( (X, \tau) \) is a topological space that is not a metric space.

Solution To see that \( (X, \tau) \) is a topological space, it suffices to observe that the union or intersection of any elements of \( \tau \) also belongs to \( \tau \).

We now show that \( (X, \tau) \) is not a metric space, that is, there is no way to define a metric on \( X \) such that the resulting open sets are precisely the elements of \( \tau \). We verify this by contradiction. Assume, to the contrary, that there exists a metric \( d \) such that the open sets in \( (X, d) \) are the elements of \( \tau \). Let \( r = \min\{d(a, b), d(b, c)\} \). Necessarily, \( r > 0 \). Then

\[
S_r(b) = \{x \in X : d(x, b) < r\} = \{b\},
\]

which, however, does not belong to \( \tau \), a contradiction.

We now present two other examples of topological spaces, the first of which is suggested by the preceding result.

Result 19.19 Let \( X \) be a nonempty set. For \( a \in X \), let \( \tau \) consist of \( \emptyset \) and each subset of \( X \) containing \( a \). Then \( (X, \tau) \) is a topological space.

Proof Since \( a \in X \), it follows that \( X \in \tau \). Furthermore, \( \emptyset \in \tau \), so property (1) is satisfied. Let \( O_1, O_2, \ldots, O_n \) be \( n \) elements of \( \tau \). If \( O_i = \emptyset \) for some \( i \) (\( 1 \leq i \leq n \)), then \( \bigcap_{i=1}^n O_i = \emptyset \) and so \( \bigcap_{i=1}^n O_i \in \tau \). Otherwise, \( a \in O_i \) for all \( i \) with \( 1 \leq i \leq n \). Thus, \( a \in \bigcap_{i=1}^n O_i \), implying that \( \bigcap_{i=1}^n O_i \in \tau \). Finally, for an index set \( I \), let \( \{O_\alpha\}_{\alpha \in I} \) be a collection of
elements of $\tau$. If $O_\alpha = \emptyset$ for all $\alpha \in I$, then $\bigcup_{\alpha \in I} O_\alpha = \emptyset$ and so $\bigcup_{\alpha \in I} O_\alpha \in \tau$. Otherwise, $a \in O_\alpha$ for some $\alpha \in I$ and so $a \in \bigcup_{\alpha \in I} O_\alpha$. Therefore, $\bigcup_{\alpha \in I} O_\alpha \in \tau$. Hence, $(X, \tau)$ is a topological space.

Our next example of a topological space uses the Extended De Morgan’s Laws (Theorem 19.12).

**Result to Prove** Let $X$ be a nonempty set, and let $\tau$ be the set consisting of $\emptyset$ and each subset of $X$ whose complement is finite. Then $(X, \tau)$ is a topological space.

**Proof Strategy** If $X$ is a finite set, then $\tau$ consists of all subsets of $X$. In this case, $\tau$ is the discrete topology on $X$ and $(X, \tau)$ is a topological space. Hence, we need only be concerned with the case when $X$ is infinite. We already know that $\emptyset \in \tau$. Also $\overline{\emptyset}$, which is finite, so $X \in \tau$ as well. So, $(X, \tau)$ satisfies property (1) required of a topological space.

In order to show that $(X, \tau)$ satisfies property (2), we let $O_1, O_2, \ldots, O_n \in \tau$ for $n \in \mathbb{N}$. We are required to show that $\bigcap_{i=1}^n O_i \in \tau$. If any of the open sets $O_1, O_2, \ldots, O_n$ is empty, then $\bigcap_{i=1}^n O_i = \emptyset$ and so $\bigcap_{i=1}^n O_i$ belongs to $\tau$. Hence, it suffices to assume that $O_i \neq \emptyset$ for all $i (1 \leq i \leq n)$. It is necessary to show that $\bigcap_{i=1}^n O_i$ is finite. However, $\bigcap_{i=1}^n O_i = \bigcup_{i=1}^n \overline{O_i}$ by De Morgan’s law. Since each set $\overline{O_i}$ is finite (1 \leq i \leq n), the union of these sets is finite as well. Therefore, $\bigcap_{i=1}^n O_i \in \tau$ and property (2) is satisfied.

To show that property (3) is satisfied, we begin with an indexed family $\{O_\alpha\}_{\alpha \in I}$ of open sets in $X$ and require to show that $\bigcup_{\alpha \in I} O_\alpha \in \tau$. We can proceed in a manner similar to the verification of property (2).

**Result 19.20** Let $X$ be a nonempty set and let $\tau$ be the set consisting of $\emptyset$ and each subset of $X$ whose complement is finite. Then $(X, \tau)$ is a topological space.

**Proof** If $X$ is finite, then $\tau$ is the discrete topology. Hence, we may assume that $X$ is infinite. Since the complement of $X$ is $\emptyset$, it follows that $X \in \tau$. Since $\emptyset \in \tau$ as well, (1) holds.

Let $O_1, O_2, \ldots, O_n$ be $n$ elements of $\tau$. If $O_i = \emptyset$ for some $i (1 \leq i \leq n)$, then $\bigcap_{i=1}^n O_i = \emptyset \in \tau$. Hence, we may assume that $O_i \neq \emptyset$ for all $i (1 \leq i \leq n)$. Then each set $\overline{O_i}$ is finite.

By De Morgan’s law, $\bigcap_{i=1}^n O_i = \bigcup_{i=1}^n \overline{O_i}$. Since $\bigcap_{i=1}^n O_i$ is a finite union of finite sets, it is finite. Thus, $\bigcap_{i=1}^n O_i \in \tau$ and so (2) is satisfied. To verify (3), let $\{O_\alpha\}_{\alpha \in I}$ be any collection of elements of $\tau$. Again, by De Morgan’s law,

$$\bigcup_{\alpha \in I} O_\alpha = \bigcap_{\alpha \in I} \overline{O_\alpha}.$$ 

If $O_\alpha = \emptyset$ for all $\alpha \in I$, then $\bigcup_{\alpha \in I} O_\alpha = \emptyset \in \tau$. Thus, we may assume that there is some $\beta \in I$ such that $O_\beta \neq \emptyset$. Hence, $\overline{O_\beta}$ is finite and $\bigcap_{\alpha \in I} O_\alpha \subseteq \overline{O_\beta}$. So, $\bigcap_{\alpha \in I} \overline{O_\alpha}$ is finite as well. Therefore, $\bigcup_{\alpha \in I} O_\alpha \in \tau$ and (3) is satisfied.

We saw in Theorem 19.7 that every two distinct points in a metric space $(X, d)$ belong to disjoint open spheres in $X$. Since open spheres are open sets in $X$, it follows that two distinct points in $X$ belong to disjoint open sets. This is often a useful property for a topological space to have.
A topological space \((X, \tau)\) is called a **Hausdorff space** (named for the mathematician Felix Hausdorff) if for each pair \(a, b\) of distinct points of \(X\), there exist disjoint open sets \(O_a\) and \(O_b\) of \(X\) containing \(a\) and \(b\), respectively. The following result is a consequence of Theorem 19.7.

**Corollary 19.21** Every metric space is a Hausdorff space.

On the other hand, not every topological space is a Hausdorff space and not every Hausdorff space is a metric space. We verify the first of these. The second of these is a deeper question in topology.

**Example 19.22** Let \(X\) be an infinite set and let \(\tau\) be the set consisting of \(\emptyset\) and every subset of \(X\) whose complement is finite. Then \((X, \tau)\) is a topological space that is not a Hausdorff space.

**Solution** We saw in Result 19.20 that \((X, \tau)\) is a topological space, so it remains only to show that \((X, \tau)\) is not a Hausdorff space. Let \(a\) and \(b\) be any two distinct elements of \(X\). We claim that there do not exist two disjoint open sets, one containing \(a\) and the other \(b\). Assume, to the contrary, that there exist (nonempty) open sets \(O_a\) and \(O_b\) containing \(a\) and \(b\), respectively, such that \(O_a \cap O_b = \emptyset\). Then, by De Morgan's law, \(O_a \cap O_b = X = \overline{O_a} \cup \overline{O_b}\). Since \(X\) is infinite, at least one of \(\overline{O_a}\) and \(\overline{O_b}\) is infinite. This implies that at least one of \(O_a\) and \(O_b\) is not open, which is a contradiction.

**19.5 CONTINUITY IN TOPOLOGICAL SPACES**

By Theorem 19.16, if \((X, d)\) and \((Y, d')\) are metric spaces, then a function \(f : X \to Y\) is continuous if and only if \(f^{-1}(O)\) is an open set in \(X\) for each open set \(O\) in \(Y\). Hence, instead of defining a function \(f\) to be continuous in terms of distances in the two metric spaces (as we did), we could have defined \(f\) to be continuous in terms of open sets. Since it would be meaningless to define a function from one topological space to another to be continuous in terms of distance, we have a logical alternative.

Let \((X, \tau)\) and \((Y, \tau')\) be two topological spaces. A function \(f : X \to Y\) is defined to be **continuous** if \(f^{-1}(O)\) is an open set in \(X\) for every open set \(O\) in \(Y\). Let's see how this definition works in practice.

**Result 19.23** Let \((X, \tau)\) and \((Y, \tau')\) be two topological spaces.

(i) If \(\tau\) is the discrete topology on \(X\), then every function \(f : X \to Y\) is continuous.

(ii) Let \(\tau\) be the trivial topology on \(X\) and let \(f : X \to Y\) be a surjective function. Then \(f\) is continuous if and only if \(\tau'\) is the trivial topology on \(Y\).

**Proof** First we verify (i). Let \(O\) be an open set in \(Y\). Since \(f^{-1}(O)\) is a subset of \(X\), it follows that \(f^{-1}(O)\) is an open set in \(X\) and so \(f\) is continuous.

Next we verify (ii). Assume first that \(\tau'\) is the trivial topology on \(Y\). Then \(Y\) and \(\emptyset\) are the only open sets in \(Y\). Since \(f^{-1}(Y) = X\) and \(f^{-1}(\emptyset) = \emptyset\) are open sets in \(X\), it follows that \(f\) is continuous. For the converse, assume that \(\tau'\) is a topology on \(Y\) that is
not the trivial topology. Then there exists some open set \( O \) in \( Y \) distinct from \( Y \) and \( \emptyset \). Since \( f \) is surjective, \( f^{-1}(O) \) is distinct from \( X \) and \( \emptyset \). Thus, \( f^{-1}(O) \) is not an open set in \( X \), implying that \( f \) is not continuous.

\[ \Box \]

**Result 19.24** Let \((X, \tau)\) and \((Y, \tau')\) be topological spaces.

(i) The identity function \( i : X \to X \) (defined by \( i(x) = x \) for all \( x \in X \)) is continuous.

(ii) If \( g : X \to Y \) is a constant function, that is, if \( g(x) = c \) for all \( x \in X \), where \( c \in Y \), then \( g \) is continuous.

**Proof** We first verify (i). Let \( O \) be an open set in \( X \). Since \( i^{-1}(O) = O \) is an open set in \( X \), the function \( i \) is continuous.

Next we verify (ii). Let \( O \) be an open set in \( Y \). If \( c \in O \), then \( g^{-1}(O) = X \); while if \( c \notin O \), then \( g^{-1}(O) = \emptyset \). In either case, \( g^{-1}(O) \) is an open set in \( X \) and so \( g \) is continuous.

\[ \Box \]

**Example 19.25** Let \( X = \{a, b, c\} \) with the topology \( \tau = \{\emptyset, X, \{a\}, \{a, b\}, \{a, c\}\} \) and let \( f : X \to X \) be defined by \( f(a) = b \), \( f(b) = c \) and \( f(c) = a \). Determine whether \( f \) is continuous.

**Solution** Since \( O = \{a\} \) is an open set in \( X \) and \( f^{-1}(O) = \{c\} \) is not an open set in \( X \), the function \( f \) is not continuous.

Based on the definition given of a continuous function from one metric space to another, it might appear more natural, for topological spaces \((X, \tau)\) and \((Y, \tau')\), to define a function \( f : X \to Y \) to be continuous if, for every \( x \in X \) and every open set \( O \) of \( Y \) containing \( f(x) \), there exists an open set \( U \) of \( X \) containing \( x \) such that \( f(U) \subseteq O \). This, however, turns out to be equivalent to our definition, as we are about to see. First, a lemma is useful.

**Lemma 19.26** Let \( X \) and \( Y \) be nonempty sets and let \( f : X \to Y \) be a function. For every subset \( B \) of \( Y \),

\[ f \left( f^{-1}(B) \right) \subseteq B. \]

**Proof** Let \( y \in f \left( f^{-1}(B) \right) \). Then there is \( x \in f^{-1}(B) \) such that \( f(x) = y \). This implies that \( y \in B \).

\[ \Box \]

**Result to Prove** Let \((X, \tau)\) and \((Y, \tau')\) be topological spaces. Then \( f : X \to Y \) is continuous if and only if for every \( x \in X \) and every open set \( O \) of \( Y \) containing \( f(x) \), there exists an open set \( U \) of \( X \) containing \( x \) such that \( f(U) \subseteq O \).

**PROOF STRATEGY** Assume first that \( f \) is continuous. Let \( x \in X \) and let \( O \) be an open set in \( Y \) containing \( y = f(x) \). What we are required to do is to find an open set \( U \) of \( X \) containing \( x \) such that \( f(U) \subseteq O \). There is an obvious choice for \( U \), however, namely, \( f^{-1}(O) \). An application of Lemma 19.26 will complete the proof of this implication.

Next, we consider the converse. Assume that for every \( x \in X \) and every open set \( O \) of \( Y \) containing \( f(x) \), there is an open set \( U \) of \( X \) containing \( x \) such that \( f(U) \subseteq O \). Since our goal is to show that \( f \) is continuous, we need to show that for every open set \( B \) of
Chapter 19  Proofs in Topology

Let \( f : X \to Y \) be a function. The set \( f^{-1}(B) \) is open in \( X \). Of course, if \( f^{-1}(B) = \emptyset \), then \( f^{-1}(B) \) is an open set; so we assume that \( f^{-1}(B) \neq \emptyset \). If we can show that \( f^{-1}(B) \) is the union of open sets, then \( f^{-1}(B) \) is open. Let \( x \in f^{-1}(B) \). Then \( f(x) \in B \). By hypothesis, there is an open set \( U_x \) in \( X \) containing \( x \) such that \( f(U_x) \subseteq B \). This implies that \( f^{-1}(B) \) is a union of open sets in \( X \).

\[ \text{Result 19.27} \]

Let \((X, \tau)\) and \((Y, \tau')\) be topological spaces. Then \( f : X \to Y \) is continuous if and only if for every \( x \in X \) and every open set \( O \) of \( Y \) containing \( f(x) \), there exists an open set \( U \) of \( X \) containing \( x \) such that \( f(U) \subseteq O \).

\[ \text{Proof} \]

Assume first that \( f \) is continuous. Let \( x \in X \) and let \( O \) be an open set in \( Y \) that contains \( f(x) \). Since \( f \) is continuous, \( f^{-1}(O) \) is an open set in \( X \) containing \( x \). Let \( U = f^{-1}(O) \). By Lemma 19.26, \( f(U) = f(f^{-1}(O)) \subseteq O \).

For the converse, assume that for every \( x \in X \) and every open set \( O \) of \( Y \) containing \( f(x) \), there is an open set \( U \) of \( X \) containing \( x \) such that \( f(U) \subseteq O \). Let \( B \) be an open set in \( Y \). We show that \( f^{-1}(B) \) is an open set in \( X \). If \( f^{-1}(B) = \emptyset \), then \( f^{-1}(B) \) is open in \( X \).

So, we may assume that \( f^{-1}(B) \neq \emptyset \). For each \( x \in f^{-1}(B) \), the set \( B \) is an open set in \( Y \) containing \( f(x) \). By assumption, there is an open set \( U_x \) in \( X \) containing \( x \) such that \( f(U_x) \subseteq B \). Thus, \( U_x \subseteq f^{-1}(B) \). However, then, \( f^{-1}(B) = \bigcup_{x \in f^{-1}(B)} U_x \) and so \( f^{-1}(B) \) is an open set in \( X \) as well.

EXERCISES FOR CHAPTER 19

19.1. In each of the following, a distance is defined on the set \( \mathbb{R} \) of real numbers. Determine which of the four properties of a metric space are satisfied by \( d \). Verify your answers.

\[
\begin{align*}
(a) \quad d(x, y) &= y - x \\
(b) \quad d(x, y) &= (x - y) + (y - x) \\
(c) \quad d(x, y) &= |x - y| + |y - x| \\
(d) \quad d(x, y) &= x^2 + y^2 \\
(e) \quad d(x, y) &= |x^2 - y^2| \\
(f) \quad d(x, y) &= |x^3 - y^3|
\end{align*}
\]

19.2. Prove Result 19.5, that is, the Manhattan metric is, in fact, a metric on \( \mathbb{R}^2 \).

19.3. Let \((X, d)\) be a metric space. For two points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) in \( X \times X \), define \( d' : X \times X \to \mathbb{R} \) by \( d'(P_1, P_2) = d(x_1, x_2) + d(y_1, y_2) \). Which of the four properties of a metric space are satisfied by \( d' \)?

19.4. Let \((X, d)\) be a metric space. For two points \( P_1 = (x_1, y_1) \) and \( P_2 = (x_2, y_2) \) in \( X \times X \), define \( d^* : X \times X \to \mathbb{R} \) by \( d^*(P_1, P_2) = \sqrt{[d(x_1, x_2)]^2 + [d(y_1, y_2)]^2} \). Which of the four properties of a metric space are satisfied by \( d^* \)?

19.5. Let \( A \) be a set and let \( a \) and \( b \) be two distinct elements of \( A \). A distance \( d : A \times A \to \mathbb{R} \) is defined as follows:

\[
d(x, y) = \begin{cases} 
0 & \text{if } x = y \\
1 & \text{if } \{x, y\} = \{a, b\} \\
2 & \text{if } x \neq y \text{ and } \{x, y\} \neq \{a, b\}.
\end{cases}
\]

Which of the four properties of a metric space are satisfied by this distance?

19.6. Let \((X, d)\) be a metric space.

(a) Define \( d_1(x, y) = d(x, y) / [1 + d(x, y)] \). Prove that \( d_1 \) is a metric for \( X \).

(b) Define \( d_2(x, y) = \min\{1, d(x, y)\} \). Prove that \( d_2 \) is a metric for \( X \).
19.7. In each part that follows, a distance \(d(P_1, P_2)\) between two points \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\) is defined on the Cartesian product \(\mathbb{R}^2\). Determine which of the four properties of a metric space is satisfied by each distance \(d\). For those distances that are metrics, describe the associated open spheres.

(a) \(d(P_1, P_2) = \min\{ |x_1 - x_2|, |y_1 - y_2|\}\)

(b) \(d(P_1, P_2) = \max\{ |x_1 - x_2|, |y_1 - y_2|\}\)

(c) \(d(P_1, P_2) = (|x_1 - x_2| + |y_1 - y_2|)/2\)

19.8. Let \((\mathbb{R}^2, d)\) be the metric space whose distance \(d(P_1, P_2)\) between two points \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\) is given by \(d(P_1, P_2) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}\). Prove that the set \(S = \{(x, y) : -1 < x < 1\text{ and } -1 < y < 1\}\) is open in \((\mathbb{R}^2, d)\).

19.9. Let \((\mathbb{R}^2, d)\) and \((\mathbb{R}^2, d')\) be metric spaces, where for two points \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\) in \(\mathbb{R}^2\),

\[d(P_1, P_2) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}\]

and \(d'(P_1, P_2) = |x_1 - x_2| + |y_1 - y_2|\). Prove each of the following.

(a) Every open set in \((\mathbb{R}^2, d)\) is open in \((\mathbb{R}^2, d')\).

(b) Every open set in \((\mathbb{R}^2, d')\) is open in \((\mathbb{R}^2, d)\).

19.10. In the metric space \((\mathbb{R}, d)\), where \(d(x, y) = |x - y|\), determine which of the following sets are open, closed or neither and verify your answers.

(a) \([0, 1]\)

(b) \([0, 1]\)

(c) \((-\infty, 1]\)

(d) \((0, \infty)\)

(e) \((0, 2) - \{1\}\)

(f) \(\mathbb{Q}\)

(g) \([1 \leq n \in \mathbb{N}]\)

(h) \([\frac{1}{n} | n \in \mathbb{N}] \cup \{0\}\)

19.11. Let \((\mathbb{R}^2, d)\) be the metric space whose distance \(d(P_1, P_2)\) between two points \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\) in \(\mathbb{R}^2\) is defined by \(d(P_1, P_2) = |x_1 - x_2| + |y_1 - y_2|\) and let \((\mathbb{R}, d')\) be the metric space with \(d'(a, b) = |a - b|\).

Verify each of the following.

(a) The function \(f : (\mathbb{R}^2, d) \to (\mathbb{R}, d')\) defined by \(f(x, y) = \frac{1}{2}(x - y)\) is continuous.

(b) The function \(g : (\mathbb{R}^2, d) \to (\mathbb{R}, d')\) defined by \(g(x, y) = x\) is continuous.

19.12. Let \((\mathbb{R}^2, d)\) be the metric space whose distance \(d(P_1, P_2)\) between two points \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\) in \(\mathbb{R}^2\) is defined by \(d(P_1, P_2) = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}\) and let \(d'\) be the discrete metric, that is,

\[d'(P_1, P_2) = \begin{cases} 0 & \text{if } P_1 = P_2 \\ 1 & \text{if } P_1 \neq P_2. \end{cases}\]

Verify each of the following.

(a) The function \(f : (\mathbb{R}^2, d) \to (\mathbb{R}^2, d')\) defined by \(f(x, y) = (x, y)\) is continuous.

(b) The function \(g : (\mathbb{R}^2, d') \to (\mathbb{R}^2, d)\) defined by \(g(x, y) = (x, y)\) is not continuous.

19.13. Let \(X = \{a, b, c, d\}\). Determine which of the following collections of subsets of \(X\) are topologies on \(X\). Verify your answers.

(a) \(S_1 = \emptyset, \{a\}, \{a, b\}, \{a, c\}\)

(b) \(S_2 = \emptyset, X, \{a, b\}, \{a, c\}\)

(c) \(S_3 = \emptyset, X, \{a\}, \{a, b\}, \{a, d\}, \{a, b, d\}\)

19.15. Let \(X\) be a nonempty set and let \(S \subseteq X\). Let \(\tau\) consist of \(\emptyset\) and each subset of \(X\) containing \(S\). Prove that \((X, \tau)\) is a topological space.

19.16. Let \((X, \tau)\) be a topological space. Prove that if \(\{x\}\) is an open set for every \(x \in X\), then \(\tau\) is the discrete topology.
20 Chapter 19 Proofs in Topology

19.17. Let \((X, \tau)\) be a topological space, where \(X\) is finite. Prove that \((X, \tau)\) is a metric space if and only if \(\tau\) is the discrete topology on \(X\).

19.18. (a) For a set \(X\) with \(a \in X\), let \(\tau\) consist of \(X\) together with all sets \(S\) such that \(a \notin S\). Prove that \((X, \tau)\) is a topological space.

(b) State and prove a generalization of the result in (a).

19.19. Let \(X\) be a nonempty set and let \(\tau\) be the set consisting of \(\emptyset\) and each subset of \(X\) whose complement is countable. Prove that \((X, \tau)\) is a topological space.

19.20. Let \(a, b, c\) be three distinct elements in a Hausdorff space \((X, \tau)\). Prove that there exist pairwise disjoint open sets \(O_a, O_b\) and \(O_c\) containing \(a, b\) and \(c\), respectively.

19.21. Let \(\tau\) be the set consisting of \(\emptyset, R\) and each interval \((a, \infty)\), where \(a \in R\). It is known that \((R, \tau)\) is a topological space. (Don’t attempt to prove this.) Show that \((R, \tau)\) is not a Hausdorff space.

19.22. Prove that if \((X, \tau)\) is a topological space with the discrete topology, then \((X, \tau)\) is a Hausdorff space.

19.23. Let \((N, \tau)\) be a topological space, where \(\tau\) consists of \(\emptyset\) and \(\{S : S \subseteq \mathbb{N}, 1 \in S\}\), and let \(f : N \to \mathbb{N}\) be a continuous permutation. Determine \(f(1)\).

19.24. Let \(X = \{a, b, c\}\) with the topology \(\tau = \{\emptyset, X, \{a\}, \{a, b\}, \{a, c\}\}\). Determine all continuous functions from \(X\) to \(X\).

19.25. Let \((X, \tau_1)\), \((Y, \tau_2)\) and \((Z, \tau_3)\) be topological spaces and let \(f : X \to Y\) and \(g : Y \to Z\) be functions. Prove that if \(f\) and \(g\) are continuous, then the composition \(g \circ f\) is a continuous function from \(X\) to \(Z\).

19.26. Let \(\tau\) be the trivial topology on a nonempty set \(X\). Prove that if \(f : X \to X\) is continuous, then \(f\) is a constant function.

19.27. For the following statement \(S\) and proposed proof, either (1) \(S\) is true and the proof is correct, (2) \(S\) is true and the proof is incorrect or (3) \(S\) is false and the proof is incorrect. Explain which of these occurs.

\[ S: \quad \text{Let } X \text{ be an infinite set and let } \tau \text{ consist of } \emptyset \text{ and all infinite subsets of } X. \text{ Then } (X, \tau) \text{ is a topological space.} \]

**Proof** Since \(X\) is an infinite subset of \(X\), it follows that \(X \in \tau\). Since \(\emptyset \in \tau\), property (1) of a topological space is satisfied. Let \(O_1, O_2, \ldots, O_n\) be elements of \(\tau\) for \(n \in \mathbb{N}\). We show that \(\bigcap_{i=1}^{n} O_i \in \tau\). If \(O_i = \emptyset\) for some \(i\) with \(1 \leq i \leq n\), then \(\bigcap_{i=1}^{n} O_i = \emptyset\) and \(\bigcap_{i=1}^{n} O_i \in \tau\). Otherwise, \(O_i\) is infinite for all \(i(\leq i \leq n)\). Hence, \(\bigcap_{i=1}^{n} O_i\) is infinite and so \(\bigcap_{i=1}^{n} O_i \in \tau\). Thus, property (2) is satisfied. Next, let \(\{O_{\alpha}\}_{\alpha \in I}\) be an indexed family of open sets. If \(O_{\alpha} = \emptyset\) for each \(\alpha \in I\), then \(\bigcup_{\alpha \in I} O_{\alpha} = \emptyset\) and so \(\bigcup_{\alpha \in I} O_{\alpha} \in \tau\). Otherwise, \(O_{\alpha}\) is infinite for some \(\alpha \in I\) and so \(\bigcup_{\alpha \in I} O_{\alpha}\) is infinite. Hence, \(\bigcup_{\alpha \in I} O_{\alpha} \in \tau\). Therefore, \(\tau\) is a topology on \(X\).

19.28. Let \((X, \tau)\) and \((Y, \tau')\) be two topological spaces. According to Result 19.23(i), if \(\tau\) is the discrete topology on \(X\), then every function \(f : X \to Y\) is continuous. The converse of Result 19.23(i) is stated as follows together with a “proof.”

**Converse of Result 19.23(i):** Let \((X, \tau)\) and \((Y, \tau')\) be two topological spaces. If every function from \(X\) to \(Y\) is continuous, then \(\tau\) is the discrete topology on \(X\).

**Proof** Suppose that every function \(f : X \to Y\) is continuous and assume, to the contrary, that \(\tau\) is not the discrete topology on \(X\). Then there exists some subset \(S\) of \(X\) such that \(S\) is not open in \(X\). So, \(S\) is distinct from \(X\) and \(\emptyset\). Let \(T\) be an open set in \(Y\) and let \(a, b \in Y\) such that \(a \in T\) and \(b \notin T\). Define a function \(f : X \to Y\) by

\[
f(x) = \begin{cases} 
a & \text{if } x \in S \\
b & \text{if } x \notin S. \end{cases}
\]

Since \(T\) is open in \(Y\) and \(f^{-1}(T) = S\) is not open in \(X\), it follows that \(f\) is not continuous, which is a contradiction.
Exercises for Chapter 19

(a) Is the proposed proof of the converse correct?
(b) If the answer to (a) is yes, then state Result 19.23(i) and its converse using “if and only if.” If the answer to (a) is no, then revise the hypothesis of the converse so that it is true (with attached proof).

19.29. Let \( X \) be a set with at least two elements and let \( a \in X \). Prove or disprove:
(a) If \((X, d)\) is a metric space, then \( X - \{a\} \) is an open set.
(b) If \((X, d)\) is a topological space, then \( X - \{a\} \) is an open set.

19.30. For the following statement \( S \) and proposed proof, either (1) \( S \) is true and the proof is correct, (2) \( S \) is true and the proof is incorrect, or (3) \( S \) is false and the proof is incorrect. Explain which of these occurs.

\( S \): Let \((X, d)\) be a metric space. For every open set \( O \) in \( X \) such that \( O \neq \emptyset \) and every element \( b \in \overline{O} \), there exists an open sphere \( S_r(b) \) in \( X \) such that \( S_r(b) \) and \( O \) are disjoint.

\( \text{Proof} \) Let \( r = \min\{d(b, x) : x \in O\} \). Consider the open sphere \( S_r(b) \). We claim that \( S_r(b) \cap O = \emptyset \). Assume, to the contrary, that \( S_r(b) \cap O \neq \emptyset \). Then there exists \( y \in S_r(b) \cap O \). Since \( y \in S_r(b) \), it follows that \( d(b, y) < r \). However, since \( y \in O \), this contradicts the fact that \( r \) is the minimum distance between \( b \) and an element of \( O \).

19.31. Prove or disprove: Let \((X, d)\) be a metric space. For every open set \( O \) in \( X \) such that \( O \neq \emptyset \), there exist \( b \in \overline{O} \) and an open sphere \( S_r(b) \) in \( X \) such that \( S_r(b) \) and \( O \) are disjoint.
Answers to Odd-Numbered Section Exercises

EXERCISES FOR CHAPTER 1

Section 1.1: Describing a Set

1.1 Only (d) and (e).
1.3 (a) \(|A| = 5\), (b) \(|B| = 11\), (c) \(|C| = 51\), (d) \(|D| = 2\), (e) \(|E| = 1\), (f) \(|F| = 2\)
1.5 (a) \(A = \{-1, -2, -3, \ldots\} = \{x \in \mathbb{Z} : x \leq -1\}\)
   (b) \(B = \{-3, -2, \ldots, 3\} = \{x \in \mathbb{Z} : -3 \leq x \leq 3\} = \{x \in \mathbb{Z} : |x| \leq 3\}\)
   (c) \(C = \{-2, -1, 1, 2\} = \{x \in \mathbb{Z} : -2 \leq x \leq 2, x \neq 0\} = \{x \in \mathbb{Z} : 0 < |x| \leq 2\}\)
1.7 (a) \(A = \{\cdots, -4, -1, 2, 5, 8, \cdots\} = \{3x + 2 : x \in \mathbb{Z}\}\)
   (b) \(B = \{\cdots, -10, -5, 0, 5, 10, \cdots\} = \{5x : x \in \mathbb{Z}\}\)
   (c) \(C = \{1, 8, 27, 64, 125, \cdots\} = \{x^3 : x \in \mathbb{N}\}\)
1.9 \(A = \{2, 3, 5, 7, 8, 10, 13\}\)
   \(B = \{x \in A : x = y + z, \text{ where } y, z \in A\} = \{5, 7, 8, 10, 13\}\)
   \(C = \{r \in B : r + s \in B \text{ for some } s \in B\} = \{5, 8\}\).

Section 1.2: Subsets

1.11 Let \(r = \min(c - a, b - c)\) and let \(I = (c - r, c + r)\). Then \(I\) is centered at \(c\) and \(I \subseteq (a, b)\).
1.13 See Figure 1.1.

![Figure 1.1](image)

Figure 1.1 Answer for Exercise 1.13

1.15 \(\mathcal{P}(A) = \{\emptyset, \{0\}, \{\emptyset\}, A\}\)
1.17 \(\mathcal{P}(A) = \{\emptyset, \{0\}, \{\emptyset\}, \{0, \emptyset\}, \{0, \{0\}\}, \{\emptyset, \{0\}\}, A\}\); \(|\mathcal{P}(A)| = 8\)
1.19 (a) \(S = \{\emptyset, \{1\}\}\). (b) \(S = \{1\}\).
   (c) \(S = \{\emptyset, \{1\}, \{2\}, \{3\}, \{4, 5\}\}\). (d) \(S = \{1, 2, 3, 4, 5\}\).
1.21 \(B = \{1, 4, 5\}\).

Section 1.3: Set Operations

1.23 Let \(A = \{1, 2, \ldots, 6\}\) and \(B = \{4, 5, \ldots, 9\}\). Then \(A - B = \{1, 2, 3\}\), \(B - A = \{7, 8, 9\}\) and \(A \cap B = \{4, 5, 6\}\).
Thus, \(|A - B| = |A \cap B| = |B - A| = 3\). See Figure 1.2.
1.25  (a)  $A = \{1\}, B = \{\{1\}\}, C = \{1, 2\}$.
(b)  $A = \{\{1\}\}, B = \{1\}, C = \{1, 2\}$.
(c)  $A = \{1\}, B = \{\{1\}\}, C = \{\{1\}, 2\}$.

1.27  Let $U = \{1, 2, \ldots, 8\}$ be a universal set, $A = \{1, 2, 3, 4\}$ and $B = \{3, 4, 5, 6\}$. Then $A \cap B = \{1, 2\}$, $B - A = \{5, 6\}$, $A \cap B = \{3, 4\}$ and $A \cup B = \{7, 8\}$. See Figure 1.3.

1.29  (a)  The sets $\emptyset$ and $\{\emptyset\}$ are elements of $A$.  (b)  $|A| = 3$.
(c)  All of $\emptyset$, $\{\emptyset\}$ and $\{\emptyset, \emptyset\}$ are subsets of $A$.  (d)  $\emptyset \cap A = \emptyset$.
(e)  $\{\emptyset\} \cap A = \{\emptyset\}$.  (f)  $\emptyset = \emptyset$.  (g)  $\emptyset = A$.  (h)  $\emptyset = A$.
(i)  $\emptyset \cup A = A$.

1.31  $A = \{1, 2\}, B = \{1\}, C = \{1, 2, 3\}, D = \{2, 3\}$.

1.33  $A = \{1\}, B = \{2\}$. Then $\{A \cup B, A \cap B, A - B, B - A\}$ is the power set of $\{1, 2\}$.

1.35  Let $U = \{1, 2, \ldots, 8\}, A = \{1, 2, 3, 5\}, B = \{1, 2, 4, 6\}$ and $C = \{1, 3, 4, 7\}$. See Figure 1.4.
Section 1.4: Indexed Collections of Sets

1.37 \( \bigcup_{x \in S} X = A \cup B \cup C = \{0, 1, 2, \ldots, 5\} \) and \( \bigcap_{y \in S} X = A \cap B \cap C = \{2\} \).

1.39 Since \( |A| = 26 \) and \( |A_x| = 3 \) for each \( x \in A \), we need to have at least nine sets of cardinality 3 for their union to be \( A \); that is, in order for \( \bigcup_{x \in S} A_x = A \), we must have \( |S| \geq 9 \). However, if we let \( S = \{a, a, \ldots, g, f, e, m, p, s, v, y\} \), then \( \bigcup_{x \in S} A_x = A \). Hence, the smallest cardinality of a set \( S \) with \( \bigcup_{x \in S} A_x = A \) is 9.

1.41 (a) \( \{A_n\}_{n \in \mathbb{N}} \), where \( A_n = \{x \in \mathbb{R} : 0 \leq x \leq 1/n\} = [0, 1/n] \).

(b) \( \{A_n\}_{n \in \mathbb{N}} \), where \( A_n = \{a \in \mathbb{Z} : |a| \leq n\} = [-n, -n-1, \ldots, n-1, n] \).

1.43 \( \bigcup_{x \in \mathbb{R}} A_x = \bigcup_{x \in \mathbb{R}^+} (-r, r) = \mathbb{R} \); \( \bigcap_{x \in \mathbb{R}^+} A_x = \bigcap_{x \in \mathbb{R}^+} (-r, r) = [0] \).

1.45 \( \bigcup_{n \in \mathbb{N}} A_n = \bigcup_{n \in \mathbb{N}} \{-\frac{1}{2}, 2 - \frac{1}{n}\} = (-1, 2); \bigcap_{n \in \mathbb{N}} A_n = \bigcap_{n \in \mathbb{N}} (-\frac{1}{2}, 2 - \frac{1}{n}) = [0, 1] \).

1.47 (a) \( \{1\} \) and \( \{1\} \) (b) \( \{-1, 1\} \) and \( \emptyset \).

Section 1.5: Partitions of Sets

1.49 (a) \( S_1 \) is not a partition of \( A \) since 4 belongs to no element of \( S_1 \).

(b) \( S_2 \) is a partition of \( A \).

(c) \( S_3 \) is not a partition of \( A \) because 2, for example, belongs to two elements of \( S_3 \).

(d) \( S_4 \) is not a partition of \( A \) since \( S_4 \) is not a set of subsets of \( A \).

1.51 \( A = \{1, 2, 3, 4\} \). \( S_1 = \{\{1\}, \{2\}, \{3, 4\}\} \) and \( S_2 = \{\{1, 2\}, \{3\}, \{4\}\} \).

1.53 Let \( S = \{A_1, A_2, A_3\} \), where \( A_1 = \{x \in \mathbb{Q} : x > 1\} \), \( A_2 = \{x \in \mathbb{Q} : x < 1\} \) and \( A_3 = \{1\} \).

1.55 Let \( S = \{A_1, A_2, A_3, A_4\} \), where \( A_1 = \{x \in \mathbb{Z} : x \text{ is odd and } x \text{ is positive}\} \), \( A_2 = \{x \in \mathbb{Z} : x \text{ is odd and } x \text{ is negative}\} \), \( A_3 = \{x \in \mathbb{Z} : x \text{ is even and } x \text{ is nonnegative}\} \), \( A_4 = \{x \in \mathbb{Z} : x \text{ is even and } x \text{ is negative}\} \).

1.57 \( |P_1| = 2, |P_2| = 3, |P_3| = 5, |P_4| = 8, |P_5| = 13, |P_6| = 21 \).

Section 1.6: Cartesian Products of Sets

1.59 \( A \times B = \{(x, x), (x, y), (y, x), (y, y), (z, x), (z, y)\} \).

1.61 \( \mathcal{P}(A) = \{\emptyset, \{a\}, \{b, A\}, A \times \mathcal{P}(A) = \{(a, \emptyset), (a, \{a\}), (a, \{b\}), (a, A), (b, \emptyset), (b, \{a\}), (b, \{b\}), (b, A)\} \).

1.63 \( \mathcal{P}(A) = \{\emptyset, \{1\}, \{2\}, \{3\}, \{\emptyset, \{3\}\}, \{\emptyset, \{1, 2\}\}, \{\emptyset, \{2, 3\}\}, \{\emptyset, \{1, 2, 3\}\}, \{\emptyset, \{\emptyset, \{1\}\}, \{\emptyset, \{2\}\}, \{\emptyset, \{3\}\}, \{\emptyset, \{\emptyset\}\}, \{\emptyset, \{1, \emptyset\}\}, \{\emptyset, \{2, \emptyset\}\}, \{\emptyset, \{3, \emptyset\}\}, \{\emptyset, \{\emptyset, \emptyset\}\}, \{\emptyset, \{\emptyset, \{\emptyset\}\}\} \).

1.65 \( S = \{(3, 0), (2, 1), (1, 2), (0, 3), (-3, 0), (-2, 1), (-1, 2), (2, -1), (1, -2), (0, -3), (-2, -1), (-1, -2)\} \).

See Figure 1.5.

Figure 1.5 Answer for Exercise 1.63
Exercises for Chapter 2

1.67 \( A \times B = [-1, 3] \times [2, 6] \), which is the set of all points on and within the square bounded by \( x = -1, x = 3, y = 2 \) and \( y = 6 \).

1.69 (a)–(b) \((A \times B) \cap (B \times A) = (A \cap B) \times (B \cap A) = \{(2, 2), (2, 3), (3, 2), (3, 3)\}\).

1.71 \( \bigcup_{i=1}^{n} (A_i \times A_i) = 10 \).

EXERCISES FOR CHAPTER 2

Section 2.1: Statements

2.1 (a) A false statement (b) A true statement (c) Not a statement (d) Not a statement (an open sentence)

2.3 (a) False. \( \emptyset \) has no elements. (b) True (c) True

2.5 (a) \( \{x \in \mathbb{Z} : x > 2\} \) (b) \( \{x \in \mathbb{Z} : x \leq 2\} \)

2.7 \( 3, 5, 11, 17, 41, 59 \)

2.9 \( P(n) : \frac{n-1}{2} \) is even. \( P(n) \) is true only for \( n = 5 \) and \( n = 9 \).

Section 2.2: Negations

2.11 (a) \( \sqrt{2} \) is not a rational number.

2.13 (a) The real number \( r \) is greater than \( \sqrt{2} \).

2.15 See Figure 2.6.

\[
\begin{array}{ccc|c}
\scriptstyle P & \scriptstyle Q & \scriptstyle \sim Q & \scriptstyle P \land (\sim Q) \\
T & T & F & F \\
T & F & T & T \\
F & T & F & F \\
F & F & T & F \\
\end{array}
\]

2.17 (a) \( P \lor Q \): 15 is odd or 21 is prime. (True)

(b) \( P \land Q \): 15 is odd and 21 is prime. (False)

(c) \( \sim P \lor Q \): 15 is not odd or 21 is prime. (False)

(d) \( P \land (\sim Q) \): 15 is odd and 21 is not prime. (True)

Section 2.3: Disjunctions and Conjunctions

2.19 (a) \( \sim P \): 17 is not even (or 17 is odd). (True)

(b) \( P \lor Q \): 17 is even or 19 is prime. (True)

(c) \( P \land Q \): 17 is even and 19 is prime. (False)

(d) \( P \Rightarrow Q \): If 17 is even, then 19 is prime. (True)
434 Answers to Odd-Numbered Section Exercises

2.21 (a) \( P \Rightarrow Q \): If \( \sqrt{2} \) is rational, then \( 22/7 \) is rational. (True)
(b) \( Q \Rightarrow P \): If \( 22/7 \) is rational, then \( \sqrt{2} \) is rational. (False)
(c) \( \sim P \Rightarrow \sim Q \): If \( \sqrt{2} \) is not rational, then \( 22/7 \) is not rational. (False)
(d) \( \sim Q \Rightarrow \sim P \): If \( 22/7 \) is not rational, then \( \sqrt{2} \) is not rational. (True)

2.23 (a), (c), (d) are true.

2.25 (a) True. (b) False. (c) True. (d) True. (e) True.

2.27 Cindy and Don attended the talk.

2.29 Only (c) implies that \( P \lor Q \) is false.

Section 2.5: More on Implications

2.31 (a) \( P(x) \Rightarrow Q(x) \): If \( |x| = 4 \), then \( x = 4 \).
\( P(-4) \Rightarrow Q(-4) \) is false. \( P(-3) \Rightarrow Q(-3) \) is true.
\( P(1) \Rightarrow Q(1) \) is true. \( P(4) \Rightarrow Q(4) \) is true. \( P(5) \Rightarrow Q(5) \) is true.
(b) \( P(x) \Rightarrow Q(x) \): If \( x^2 = 16 \), then \( |x| = 4 \). True for all \( x \in S \).
(c) \( P(x) \Rightarrow Q(x) \): If \( x > 3 \), then \( 4x - 1 > 12 \). True for all \( x \in S \).

2.33 (a) True for \( (x, y) = (3, 4) \) and \( (x, y) = (5, 5) \), false for \( (x, y) = (1, -1) \).
(b) True for \( (x, y) = (1, 2) \) and \( (x, y) = (6, 6) \), false for \( (x, y) = (2, -2) \).
(c) True for \( (x, y) \in \{(1, -1), (-3, 4), (1, 0)\} \) and false for \( (x, y) = (0, -1) \).

Section 2.6: Biconditionals

2.35 \( P \iff Q \): The integer 18 is odd if and only if 25 is even. (True)

2.37 Let \( x \in \mathbb{R} \). Then \( |x - 1| < 1 \) if and only if \( |x| < 2 \).
For \( x \in \mathbb{R} \), \( |x| > 1 \) is a necessary and sufficient condition for \( x \in (2, 4) \).

2.39 (a) True for all \( x \in S \setminus \{-4\} \). (b) True for \( x \in S \setminus \{3\} \). (c) True for \( x \in S \setminus \{-4, 0\} \).

2.41 True if \( n = 3 \).

2.43 \( P(1) \Rightarrow Q(1) \) is false (since \( P(1) \) is true and \( Q(1) \) is false).
\( Q(3) \Rightarrow P(3) \) is false (since \( Q(3) \) is true and \( P(3) \) is false).
\( P(2) \iff Q(2) \) is true (since \( P(2) \) and \( Q(2) \) are both true).

2.45 True for all \( n \in S \).

Section 2.7: Tautologies and Contradictions

2.47 The compound statements \( (P \land \sim Q) \land (P \land Q) \) and \( P \Rightarrow \sim Q \land (P \land Q) \) are contradictions. See the truth table below.

2.59 Since there are only four different combinations of truth values of \(P\) and \(Q\) for the second and third rows of the statements \(S_1, S_2, S_3, S_4\) and \(S_5\), at least two of these must have identical truth tables and so are logically equivalent.
Section 2.9: Some Fundamental Properties of Logical Equivalence

2.61 (a) Both \( x \neq 0 \) and \( y \neq 0 \).
   (b) Either the integer \( a \) is odd or the integer \( b \) is odd.
2.63 Either \( x^2 = 2 \) and \( x \neq \sqrt{2} \) or \( x = \sqrt{2} \) and \( x^2 \neq 2 \).
2.65 If \( 3n + 4 \) is odd, then \( 5n - 6 \) is odd.

Section 2.10: Quantified Statements

2.67 \( \forall x \in S, P(x) \): For every odd integer \( x \), the integer \( x^2 + 1 \) is even.
   \( \exists x \in S, Q(x) \): There exists an odd integer \( x \) such that \( x^2 \) is even.
2.69 (a) There exists a set \( A \) such that \( A \cap \overline{A} \neq \emptyset \).
   (b) For every set \( A \), we have \( \overline{A} \subseteq A \).
2.71 (a) False, since \( P(1) \) is false. (b) True, for example, \( P(3) \) is true.
2.73 (a) \( \exists a, b \in \mathbb{Z}, ab < 0 \) and \( a + b > 0 \).
   (b) \( \forall x, y \in \mathbb{R}, x \neq y \) implies that \( x^2 + y^2 > 0 \).
   (c) For all integers \( a \) and \( b \) either \( ab \geq 0 \) or \( a + b \leq 0 \).
   (d) \( \exists a, b \in \mathbb{Z}, ab \geq 0 \) or \( a + b \leq 0 \).
2.75 (b) and (c) imply that \( P(x) \) \( \Rightarrow Q(x) \) is true for all \( x \in T \).
2.77 Let \( S = \{3, 5, 11\} \) and \( P(s, t) : st - 2 \) is prime.
   (a) \( \forall s, t \in S, P(s, t) \).
   (b) False since \( P(11, 11) \) is false.
   (c) \( \exists s, t \in S, \sim P(s, t) \).
   (d) There exist \( s, t \in S \) such that \( st - 2 \) is not prime.
   (e) True since the statement in (a) is false.
2.79 (a) There exists a triangle \( T_1 \) such that for every triangle \( T_2 \), \( r(T_2) \geq r(T_1) \).
   (b) \( \forall T_1 \in A, \exists T_2 \in B, \sim P(T_1, T_2) \).
   (c) For every triangle \( T_1 \), there exists a triangle \( T_2 \) such that \( r(T_2) < r(T_1) \).
2.81 (a) There exists \( b \in B \) such that for every \( a \in A, a - b < 0 \).
   (b) Let \( b = 10 \). Then \( 3 - 10 = -7 \leq 0 \).

Section 2.11: Characterizations

2.83 An integer \( n \) is odd if and only if \( n^2 \) is odd.
2.85 (a) A characterization. (b) A characterization. (c) A characterization.
   (d) A characterization. (Pythagorean theorem) (e) Not a characterization. (Every positive number is the area of some rectangle.)

EXERCISES FOR CHAPTER 3

Section 3.1: Trivial and Vacuous Proofs

3.1 \textbf{Proof} \quad Since \( x^2 - 2x + 2 = (x - 1)^2 + 1 \geq 1 \), it follows that \( x^2 - 2x + 2 \neq 0 \) for all \( x \in \mathbb{R} \). Hence, the statement is true trivially.
3.3 \textbf{Proof} \quad Note that \( \frac{2 + 1}{r} = r + \frac{1}{r} \). If \( r \geq 1 \), then \( r + \frac{1}{r} > 1 \); while if \( 0 < r < 1 \), then \( \frac{1}{r} > 1 \) and so \( r + \frac{1}{r} > 1 \). Thus, \( \frac{2 + 1}{r} \leq 1 \) is false for all \( r \in \mathbb{Q} \) and so the statement is true vacuously.
3.5 \textbf{Proof} \quad Since \( n^2 - 2n + 1 = (n - 1)^2 \geq 0 \), it follows that \( n^2 + 1 \geq 2n \) and so \( n + \frac{1}{n} \geq 2 \). Thus, the statement is true vacuously.
3.7 \textbf{Proof} \quad Since \( (x - y)^2 + (x - z)^2 + (y - z)^2 \geq 0 \), it follows that \( 2x^2 + 2y^2 + 2z^2 - 2xy - 2xz - 2yz \geq 0 \) and so \( x^2 + y^2 + z^2 \geq xy + xz + yz \). Thus, the statement is true vacuously.
Section 3.2: Direct Proofs

3.9 Proof Let \(x\) be an even integer. Then \(x = 2a\) for some integer \(a\). Thus,
\[
5x - 3 = 5(2a) - 3 = 10a - 4 + 1 = 2(5a - 2) + 1.
\]

Since \(5a - 2\) is an integer, \(5x - 3\) is odd.

3.11 Proof Let \(1 - n^2 > 0\). Then \(n = 0\). Thus, \(3n - 2 = 3 \cdot 0 - 2 = -2\) is an even integer.

3.13 Proof Assume that \((n + 1)^2(n + 2)^2/4\) is even, where \(n \in \mathbb{Z}\). Then \(n = 2\) and \((n + 2)^2(n + 3)^2/4 = 100\), which is even.

3.15 Proof Let \(n \in A \cap B = \{3, 5, 7, 9\}\). Then \(3^2 - 2 = 7, 5^2 - 2 = 23, 7^2 - 2 = 47\) and \(9^2 - 2 = 79\) are all primes.

Section 3.3: Proof by Contrapositive

3.17 First, we prove a lemma. Lemma Let \(n \in \mathbb{Z}\). If \(15n\) is even, then \(n\) is even.

(Use a proof by contrapositive to verify this lemma.) Then use this lemma to prove the result.

Proof of Result Assume that \(15n\) is even. By the lemma, \(n\) is even and so \(n = 2a\) for some integer \(a\). Hence, \(9n = 9(2a) = 2(9a)\). Since \(9a\) is an integer, \(9n\) is even.

[Note: This result could also be proved by assuming that \(15n\) is even (and so \(15n = 2a\) for some integer \(a\)) and observing that \(9n = 15n - 6n = 2a - 6n\).]

3.19 Lemma Let \(x \in \mathbb{Z}\). If \(7x + 4\) is even, then \(x\) is even. (Use a proof by contrapositive to verify this lemma.)

Proof of Result Assume that \(7x + 4\) is even. Then by the lemma, \(x\) is even and so \(x = 2a\) for some integer \(a\). Hence,
\[
3x - 11 = 3(2a) - 11 = 6a - 12 + 1 = 2(3a - 6) + 1.
\]

Since \(3a - 6\) is an integer, \(3x - 11\) is odd.

3.21 To verify the implication “If \(n\) is even, then \((n + 1)^2 - 1\) is even.”, use a direct proof. For the converse, “If \((n + 1)^2 - 1\) is even, then \(n\) is even.”, use a proof by contrapositive.

3.23 Proof Assume that \(n \notin A \cup B\). Then \(n = 3\) and \(n(n - 2)/6 = 1\) is odd.

3.25 Proof Assume that \(n \notin A\). Then \(n \in B = \{2, 3, 6, 7\}\). If \(n = 2\), then \((n^2 + 3n - 4)/2 = 3\) is odd. If \(n = 3\), then \((n^2 + 3n - 4)/2 = 7\) is odd. If \(n = 6\), then \((n^2 + 3n - 4)/2 = 25\) is odd. If \(n = 7\), then \((n^2 + 3n - 4)/2 = 33\) is odd.

Section 3.4: Proof by Cases

3.27 Let \(n \in \mathbb{Z}\). We consider two cases.

Case 1. \(n\) is even. Then \(n = 2a\) for some integer \(a\). Thus, \(n^3 - n = 8a^3 - 2a = 2(4a^3 - a)\). Since \(4a^3 - a\) is an integer, \(n^3 - n\) is even.

Case 2. \(n\) is odd. Then \(n = 2b + 1\) for some integer \(b\). The remainder of the proof is similar to that of Case 1.

[Another possibility is to use Theorem 3.12 to observe that \(n^3\) is odd and write \(n^2 = 2c + 1\) for some integer \(c\) and so \(n^3 = n(n^2) = (2b + 1)(2c + 1) = 2(bc + b + c) + 1\).]

3.29 Assume that \(a, b \in \mathbb{Z}\) such that \(ab\) is odd. By Exercise 3.28, \(a\) and \(b\) are both odd and so \(a^2\) and \(b^2\) are both odd by Theorem 3.12. Thus, \(a^2 + b^2\) is even.

3.31 Proof Assume that \(a\) or \(b\) is odd, say \(a\) is odd. Then \(a = 2x + 1\) for some integer \(x\). We consider two cases.

Case 1. \(b\) is even. Then \(b = 2y\) for some integer \(y\). Thus, \(ab = a(2y) = 2(ay)\). Since \(ay\) is an integer, \(ab\) is even. Also,
\[
a + b = (2x + 1) + 2y = 2(x + y) + 1.
\]

Since \(x + y\) is an integer, \(a + b\) is even. Hence, \(ab\) and \(a + b\) are of opposite parity.

Case 2. \(b\) is odd. Then \(b = 2y + 1\) for some integer \(y\). Thus,
\[
a + b = (2x + 1) + (2y + 1) = 2x + 2y + 2 = 2(x + y + 1).
\]
Answers to Odd-Numbered Section Exercises

Since \( x + y + 1 \) is an integer, \( a + b \) is even. Furthermore,
\[
ab = (2x + 1)(2y + 1) = 4xy + 2x + 2y + 1 = 2(2xy + x + y) + 1.
\]
Since \( 2xy + x + y \) is an integer, \( ab \) is odd. Hence, \( ab \) and \( a + b \) are of opposite parity.

3.33 **Proof** Assume that \( n \not\in A \cap B \). Then \( n = 1 \) or \( n = 4 \). If \( n = 1 \), then \( 2n^2 - 5n = -3 \) is negative and odd; while if \( n = 4 \), then \( 2n^2 - 5n = 12 \) is positive and even.

For the converse, assume that \( n \in A \cap B \). Then \( n = 2 \) or \( n = 3 \). If \( n = 2 \), then \( 2n^2 - 5n = -2 \) is negative and even; while if \( n = 3 \), then \( 2n^2 - 5n = 3 \) is positive and odd. Thus, if \( n \not\in A \cap B \), then neither (a) nor (b) occurs.

3.35 **Proof** Let \( n \) be a nonnegative integer. We consider two cases.

Case 1. \( n = 0 \). Then \( 2^n + 2^0 = 2^0 + 2^0 = 2 \), which is even.

Case 2. \( n \) is a positive integer. Then \( n - 1 \) is a nonnegative integer. Therefore,
\[
2^n + 2^{n-1} = 2^n + (2 \cdot 3^n) = 2^n + 2^n \cdot 3^n = 2(2^n - 1 + 2^{n-1} \cdot 3^n).
\]
Since \( 2^{n-1} + 2^{n-1} \cdot 3^n \) is an integer, \( 2^n + 2^0 \) is even.

Suppose that exactly two of the three integers \( x, y, z \) are even. We consider three cases.

Case 1. \( x \) and \( y \) are even and \( z \) is odd. Then \( x = 2a, y = 2b \) and \( z = 2c + 1 \), where \( a, b, c \in \mathbb{Z} \). Thus, \( 3x + 5y + 7z = 3(2a) + 5(2b) + 7(2c + 1) = 6a + 10b + 14c + 7 = 2(3a + 5b + 7c + 3) + 1 \). Since \( 3a + 5b + 7c + 3 \) is an integer, \( 3x + 5y + 7z \) is odd.

The proofs of the following two cases are similar to that of Case 1.

Case 2. \( x \) and \( y \) are even and \( z \) is odd. \( z \) is odd.

Case 3. \( y \) and \( z \) are even and \( x \) is odd.

3.37 Use a proof by contrapositive and consider two cases.

Section 3.5: Proof Evaluations

3.41 (3) is proved.

3.43 The converse of the result has been proved. No proof has been given of the result itself.

3.45 From the first sentence of the proposed proof and the final sentence, it appears that the result in question is the following: Let \( x, y \in \mathbb{Z} \). If \( x \) or \( y \) is even, then \( xy \) is even. If this, in fact, is the result, then the proof is not correct. A proof by cases should be given, namely Case 1. \( x \) is even. and Case 2. \( y \) is even.

3.47 **Result** Let \( x \in \mathbb{Z} \). If \( 7x - 3 \) is even, then \( 3x + 8 \) is odd.

A direct proof of the result is given with the aid of the lemma: Let \( x \in \mathbb{Z} \). If \( 7x - 3 \) is even, then \( x \) is odd.

EXERCISES FOR CHAPTER 4

Section 4.1: Proofs Involving Divisibility of Integers

4.1 **Proof** Assume that \( a \mid b \). Then \( b = ac \) for some integer \( c \). Then \( b^2 = (ac)^2 = a^2c^2 \). Since \( c^2 \) is an integer, \( a^2 \mid b^2 \).

4.3 **Proof** First, assume that \( 3 \) divides one of \( x, y \) and \( z \), say \( 3 \mid x \). Then \( x = 3a \), where \( a \in \mathbb{Z} \). Then \( xyz = (3a)yz = 3(ayz) \). Since \( ayz \in \mathbb{Z} \), it follows that \( 3 \mid xyz \).

For the converse, assume that \( 3 \mid xyz \). Let \( w = yz \). Then \( 3 \mid xw \). By Result 4.8, \( 3 \mid x \) or \( 3 \mid w \). If \( 3 \mid x \), then we have the desired conclusion. If \( 3 \mid w \), then \( 3 \mid yz \) again, by Result 4.8, \( 3 \mid y \) or \( 3 \mid z \). Therefore, 3 divides one of \( x, y \) and \( z \).

4.5 **Proof** Assume that \( a \mid b \) or \( a \mid c \), say the latter. Then \( c = ak \) for some integer \( k \). Thus, \( bc = b(ak) = a(bk) \).

Since \( bk \) is an integer, \( a \mid bc \).

4.7 **Proof** First, assume that \( 3 \nmid n \). By Result 4.6(a), \( 3 \mid (n^2 - 1) \) and so \( n^2 - 1 = 3a \) for some integer \( a \). Hence, \( n^2 = 3a + 1 \). Therefore, \( 2n^2 + 1 = 2(3a + 1) + 1 = 6a + 3 = 3(2a + 1) \). Since \( 2a + 1 \) is an integer, \( 3 \mid (2n^2 + 1) \).

For the converse, assume that \( 3 \mid n \). Then \( 3 \mid n^2 \) by Result 4.6(a). Hence, \( n^2 = 3a \), where \( a \in \mathbb{Z} \). Thus, \( 2n^2 + 1 = 2(3a) + 1 = 3(2a) + 1 \). Since there is a remainder of 1 when \( 2n^2 + 1 \) is divided by 3, it follows that \( 3 \mid (2n^2 + 1) \).

4.9 \( x = 3 \).
4.11 **Proof** Let \( n \) be an odd integer such that \( 3 \nmid n \). Then \( 3 \mid (n^2 - 1) \) by Result 4.6(a) and so \( n^2 - 1 = 3a \), where \( a \in \mathbb{Z} \). By Result 4.6(b), \( 8 \mid (n^2 - 1) \) and so \( n^2 - 1 = 8b \), where \( b \in \mathbb{Z} \). Thus, \( 3a = 8b \) and so \( 3 \mid 8b \). By Result 4.8, \( 3 \mid 8 \) or \( 3 \mid b \). Since \( 3 \mid 8 \), it follows that \( 3 \mid b \). Therefore, \( b = 3c \) for some integer \( c \). Hence, \( n^2 - 1 = 8b = 8(3c) = 24c \). Since \( c \) is an integer, \( 24 \mid (n^2 - 1) \).

4.13 **Proof** First, assume that \( 3 \nmid ab \). By Result 4.8, \( 3 \nmid a \) and \( 3 \nmid b \). By Result 4.6(a), \( 3 \mid (a^2 - 1) \) and \( 3 \mid (b^2 - 1) \). Hence, \( a^2 + b^2 = 3p + 1 \) and \( b^2 + b^2 = 3q + 1 \). Therefore, \( a^2 + b^2 = 3(p + 1) + (3q + 1) = 3(p + q) + 2 \). Thus, there is a remainder of 2 when \( a^2 + b^2 \) is divided by 3. According to Theorem 4.6(a), the square of no integer has a remainder of 2 when divided by 3 and so \( c^2 \neq a^2 + b^2 \) for every integer \( c \).

### Section 4.2: Proofs Involving Congruence of Integers

4.15 **Proof** Assume that \( a \equiv b \pmod{n} \) and \( a \equiv c \pmod{n} \). Then \( n \mid (a - b) \) and \( n \mid (a - c) \). Hence, \( a - b = nx \) and \( a - c = ny \), where \( x, y \in \mathbb{Z} \). Thus, \( b = a - nx \) and \( c = a - ny \). Therefore, \( b - c = (a - nx) - (a - ny) = ny - nx = n(y - x) \). Since \( y - x \) is an integer, \( n \mid (b - c) \) and so \( b \equiv c \pmod{n} \).

4.17 **(a) Proof** Assume that \( a \equiv 1 \pmod{5} \). Then \( 5 \mid (a - 1) \). So, \( a - 1 = 5k \) for some integer \( k \). Thus, \( a = 5k + 1 \) and so

\[
a^2 = (5k + 1)^2 = 25k^2 + 10k + 1 = 5(5k^2 + 2k) + 1.
\]

Thus,

\[
a^2 - 1 = 5(5k^2 + 2k).
\]

Since \( 5k^2 + 2k \) is an integer, \( 5 \mid (a^2 - 1) \) and so \( a^2 \equiv 1 \pmod{5} \).

**Proof** Assume that \( b \equiv 1 \pmod{5} \) and so \( a^2 - 1 \equiv 1 \pmod{5} \).

4.19 **Proof** Assume that \( a \equiv 5 \pmod{6} \) and \( b \equiv 3 \pmod{4} \). Then \( 6 \mid (a - 5) \) and \( 4 \mid (b - 3) \). Thus, \( a - 5 = 6x \) and \( b - 3 = 4y \), where \( x, y \in \mathbb{Z} \). So, \( a = 6x + 5 \) and \( b = 4y + 3 \). Observe that

\[
4a + 6b = 4(6x + 5) + 6(4y + 3) = 24x + 20 + 24y + 18 = 24x + 24y + 38 = 8(3x + 3y + 4) + 6.
\]

Since \( 3x + 3y + 4 \) is an integer, \( 8(4a + 6b - 6) \) and so \( 4a + 6b \equiv 6 \pmod{8} \).

4.21 Either \( a = 3q \), \( a = 3q + 1 \) or \( a = 3q + 2 \) for some integer \( q \). We consider these three cases.

**Case 1.** \( a = 3q \).

Then \( a^3 = (3q)^3 - (3q)^3 = 27q^3 - 3q = 3(9q^3 - q) \).

Since \( 9q^3 - q \) is an integer, \( 3 \mid (a^3 - a) \) and so \( a^3 \equiv a \pmod{3} \).

The other cases are handled in a similar manner.

4.23 **Proof** Since \( 6 \mid a \), it follows that \( a \equiv 0 \pmod{6} \) and so \( a = 6q \) for some \( q \in \mathbb{Z} \). Therefore, \( a + i \equiv i \pmod{6} \) for \( i = 1, 2, \ldots, 5 \). First, assume that \( x, y \in S = \{a, a + 1, \ldots, a + 5\} \), where one of \( x \) and \( y \) is congruent to 1 modulo 6 and the other is congruent to 5 modulo 6. We may assume that \( x = a + 5 \) and \( y = a + 1 \). Then \( x = 6q + 5 \) and \( y = 6q + 1 \). Thus,

\[
x^2 - y^2 = (6q + 5)^2 - (6q + 1)^2 = (36q^2 + 60q + 25) - (36q^2 + 12q + 1)
\]

\[
= 48q + 24 = 24(2q + 1).
\]

Since \( 2q + 1 \) is an integer, \( 24 \mid (x^2 - y^2) \).

For the converse, assume that \( x \) and \( y \) are distinct odd integers in \( S \) such that one of \( x \) and \( y \) is not congruent to 1 or 5 modulo 6. Since \( a \) is even, either \( x \) or \( y \) is \( a + 3 \). There are two cases.

**Case 1.** \( x = a + 5 \) and \( y = a + 3 \). Thus, \( x = 6q + 5 \) and \( y = 6q + 3 \). Now

\[
x^2 - y^2 = (6q + 5)^2 - (6q + 3)^2 = (36q^2 + 60q + 25) - (36q^2 + 12q + 9)
\]

\[
= 24q + 16.
\]

Since \( q \) is an integer, \( 24 \mid (x^2 - y^2) \).

**Case 2.** \( x = a + 3 \) and \( y = a + 1 \). (The proof here is similar to the proof of Case 1.)

440 Answers to Odd-Numbered Section Exercises

Section 4.3: Proofs Involving Real Numbers

4.25 Proof Assume that \( x^2 - 4x = y^2 - 4y \) and \( x \neq y \). Thus, \( x^2 - y^2 - 4(x - y) = 0 \) and so 
\[
(x - y)(x + y - 4) = 0.
\]
Since \( x \neq y \), it follows that \( x + y = 4 \) and so \( x + y = 4 \).

4.27 A proof by contrapositive can be used: Assume that \( x \leq 0 \). Then \( 3x^2 + 1 \geq 1 \) and \( x^2 + x^3 \leq 0 \). Thus, 
\[
3x^2 + 1 \geq 1 > 0 \geq x^2 + x^3.
\]
4.29 Proof Let \( r \in \mathbb{R} \) such that \( |r - 1| < 1 \). Since \( |r - 1| < 1 \), it follows that \( 0 < r < 2 \). Because \( (r - 2)^2 \geq 0 \), we have 
\[
r^2 - 4r + 4 \geq 0.
\]
Thus, \( 4 \geq 4r - r^2 = r(4 - r) \). Since \( 0 < r < 2 \), it follows that \( r(4 - r) > 0 \). Dividing both sides by \( r(4 - r) \), we obtain \( \frac{4}{r(4 - r)} \geq 1 \).

4.31 Proof Since 
\[
|x| = |(x + y) + (-y)| \leq |x + y| + |-y| = |x + y| + |y|,
\]
it follows that \( |x + y| \geq |x| - |y| \).

4.33 Observe that \( r^2 + s^2 + t^2 - 3rst = \frac{1}{2}(r + s + t)(r - s)^2 + (s - t)^2 + (t - r)^2 \).

4.35 Proof Assume that \( x(x + 1) > 2 \). Then \( x^2 + x > 2 \) and so \( x^2 + x - 2 > 0 \). Thus, \( (x + 2)(x - 1) > 0 \). Therefore, either (a) \( x + 2 \) and \( x - 1 \) are both positive or (b) \( x + 2 \) and \( x - 1 \) are both negative. If (a) occurs, then \( x > 1 \); while if (b) occurs, then \( x < -2 \).

4.37 Proof Since \( (x - y)^2 + (x - z)^2 + (y - z)^2 \geq 0 \), it follows that \( 2x^2 + 2y^2 + 2z^2 \geq 2xy + 2xz + 2yz \). Dividing by 2 produces the desired inequality.

4.39 Proof Observe that 
\[
(a^2 + c^2)(b^2 + d^2) = a^2b^2 + c^2d^2 + a^2d^2 + c^2b^2
\]
\[
= (ab + cd)^2 + (ad - bc)^2 \geq (ab + cd)^2.
\]

Section 4.4: Proofs Involving Sets

4.41 First, we show that if \( A \cup B = A \), then \( B \subseteq A \). Assume that \( A \cup B = A \). Let \( x \in B \). Then \( x \in A \cup B \). Since \( A \cup B = A \), it follows that \( x \in A \). Next we show that if \( B \subseteq A \), then \( A \cup B = A \). A proof by contrapositive begins by assuming that \( A \cup B \neq A \).

4.43 (a) Consider \( A = \{1, 2\} \), \( B = \{2, 3\} \) and \( C = \{2, 4\} \).
(b) Consider \( A = \{1, 2\} \), \( B = \{1\} \) and \( C = \{2\} \).
(c) Suppose that \( B \neq C \). We show that either \( A \cap B \neq A \cap C \) or \( A \cup B \neq A \cup C \). Since \( B \neq C \), it follows that \( B \subseteq A \cup C \) or \( B \subset A \cup C \). Thus, \( B \subseteq A \) or \( B \subset A \).

Case 1. \( b \in A \). Since \( b \in B \) and \( b \in A \), it follows that \( b \in A \cap B \). On the other hand, \( b \notin A \cap C \).

Thus, \( A \cap B \neq A \cup C \).

Case 2. \( b \notin A \). Then show that \( A \cup B \neq A \cap C \).

4.45 Proof Let \( n \in \mathbb{Z} \). Then \( n \equiv 3 \mod 4 \). So, \( n = 4q + 3 \) for some integer \( q \). Therefore, \( n = 2(2q + 1) + 1 \). Since \( 2q + 1 \in \mathbb{Z} \), it follows that \( 2 \mid (n - 1) \) and so \( n \equiv 1 \mod 2 \). Thus, \( n \in \mathbb{A} \).

4.47 (a) Each element \( n \in A \) can be written as \( n = 3a + 2 \) for some integer \( a \), where \( n \) is even. This implies that \( a \) is even, say \( a = 2b \) for some integer \( b \). Thus, \( n = 3a + 2 = 3(2b) + 2 = 6b + 2 \).

(b) Proof Let \( n \in A \cap B \). Then \( n = 3a + 2 \) for some integer \( a \) and \( n \) is odd. Thus, \( a \) is odd, say \( a = 2b + 1 \) for some integer \( b \). Thus, \( n = 3a + 2 = 3(2b + 1) + 2 = 6b + 5 \). Therefore, 
\[
n^2 - 1 = (6b + 5)^2 - 1 = 36b^2 + 60b + 24 = 12(3b^2 + 5b + 2).
\]
Since \( 3b^2 + 5b + 2 \) is an integer, \( 12 \mid (n^2 - 1) \) and so \( n^2 \equiv 1 \) (mod 12).

4.49 First, we show that \( A \subseteq (A - B) \cup (A \cap B) \). Let \( x \in A \). Then \( x \notin B \) or \( x \in B \). If \( x \notin B \), then \( x \in A - B \) and \( x \in (A - B) \cup (A \cap B) \). If \( x \in B \), then \( x \in A \cap B \) and so \( x \in (A - B) \cup (A \cap B) \). Therefore, \( A \subseteq (A - B) \cup (A \cap B) \). Next, show that \( (A - B) \cup (A \cap B) \subset A \).

4.51 (e) is a necessary condition for \( A \) and \( B \) to be disjoint.
Section 4.5: Fundamental Properties of Set Operations

4.53 First, we show that \( A \cap (B \cup C) \subseteq (A \cap B) \cup (A \cap C) \). Let \( x \in A \cap (B \cup C) \). Then \( x \in A \) and \( x \in B \cup C \). Since \( x \in B \cup C \), it follows that \( x \in B \) or \( x \in C \), say \( x \in B \). Because \( x \in A \) and \( x \in B \), it follows that \( x \in A \cap B \). Hence, \( x \in (A \cap B) \cup (A \cap C) \). Next, show that \((A \cap B) \cup (A \cap C) \subseteq A \cap (B \cup C) \).

4.55 We first show that \((A - B) \cap (A - C) \subseteq (A - B) \cup (A - C) \). Let \( x \in (A - B) \cap (A - C) \). Then \( x \in A - B \) and \( x \in A - C \). Since \( x \in A - B \), it follows that \( x \in A \) and \( x \notin B \). Because \( x \in A - C \), we have \( x \in A \) and \( x \notin C \). Since \( x \notin B \) and \( x \notin C \), we have \( x \notin B \cup C \). Thus, \( x \in (A - B) \cup (A - C) \). Next, show that \((A - B) \cup (A - C) \subseteq (A - B) \cap (A - C) \).

4.57 **Proof** By Theorem 4.22,

\[
\overline{A \cap (B \cap C)} = \overline{A} \cap (\overline{B} \cup \overline{C}) = (A \cap \overline{B}) \cup (A \cap C)
\]

as desired.

4.59 First, we show that \((A - (B - C)) \subseteq (A \cap C) \cup (A - B) \). Let \( x \in A - (B - C) \). Then \( x \in A \) and \( x \notin B - C \). Since \( x \notin B - C \), it is not the case that \( x \in B \) and \( x \notin C \). Thus, either \( x \notin B \) or \( x \in C \). Since \( x \in A \), either \( x \in A - B \) or \( x \in A \cap C \). Thus, \( x \in (A \cap C) \cup (A - B) \). Therefore, \((A - (B - C)) \subseteq (A \cap C) \cup (A - B) \). Next, show that \((A \cap C) \cup (A - B) \subseteq A - (B - C) \).

Section 4.6: Proofs Involving Cartesian Products of Sets

4.61 For \( A = \{1\} \) and \( B = \{2\} \), \( \mathcal{P}(A) = \{\emptyset, A\} \) and \( \mathcal{P}(B) = \{\emptyset, B\} \). Thus,

\[
\mathcal{P}(A) \times \mathcal{P}(B) = \{(\emptyset, \emptyset), (\emptyset, B), (A, \emptyset), (A, B)\}.
\]

Since \( A \times B = \{(1, 2)\} \), it follows that \( \mathcal{P}(A \times B) = \{\emptyset, A \times B\} \).

4.63 Let \( A \) and \( B \) be sets. Then \( A \times B = B \times A \) if and only if \( A = B \) or one of \( A \) and \( B \) is empty.

**Proof** First, we show that if \( A = B \) or one of \( A \) and \( B \) is empty, then \( A \times B = B \times A \). If \( A = B \), then certainly \( A \times B = B \times A \); while if one of \( A \) and \( B \) is empty, say \( A = \emptyset \), then \( A \times B = \emptyset \times B = \emptyset = B \times \emptyset = B \times A \).

For the converse, assume that \( A \) and \( B \) are nonempty sets with \( A \neq B \). Since \( A \neq B \), at least one of \( A \) and \( B \) is not a subset of the other, say \( A \not\subseteq B \). Then there is an element \( a \in A \) such that \( a \notin B \). Since \( B \neq \emptyset \), there exists an element \( b \in B \). Then \((a, b) \in A \times B \) but \((a, b) \notin B \times A \). Hence, \( A \times B \neq B \times A \).

4.65 First, assume that \( A \times C \subseteq B \times C \). Show that \( A \subseteq B \). For the converse, assume that \( A \subseteq B \). Show that \( A \times C \subseteq B \times C \).

4.67 We first show that \( A \times (B \cap C) \subseteq (A \times B) \cap (A \times C) \). Let \((x, y) \in A \times (B \cap C) \). Then \( x \in A \) and \( y \in B \cap C \). Thus, \( y \in B \) and \( y \in C \). Therefore, \((x, y) \in A \times B \) and \((x, y) \in A \times C \). It remains to show that \((A \times B) \cap (A \times C) \subseteq A \times (B \cap C) \).

4.69 **Proof** Let \((x, y) \in (A \times B) \cup (C \times D) \). Then \((x, y) \in A \times B \) or \((x, y) \in C \times D \). Assume, without loss of generality, that \((x, y) \in A \times B \). Thus, \( x \in A \) and \( y \in B \). This implies that \( x \in A \cup C \) and \( y \in B \cup D \). Therefore, \((x, y) \in (A \cup C) \times (B \cup D) \).

EXERCISES FOR CHAPTER 5

Section 5.1: Counterexamples

5.1 Let \( a = b = -1 \). Then \( \log(ab) = \log 1 = 0 \) but \( \log(a) \) and \( \log(b) \) are not defined. Thus, \( a = b = -1 \) is a counterexample.

5.3 If \( n = 3 \), then \( 2n^2 + 1 = 19 \). Since \( 3 \nmid 19 \), it follows that \( n = 3 \) is a counterexample.

5.5 If \( a = 1 \) and \( b = 2 \), then \((a + b)^3 = 27 \), but \( a^3 + 2a^2b + 2ab + 2b^2 + b^3 = 1 + 4 + 8 + 8 + 25 = 50 \). Thus, \( a = 1 \) and \( b = 2 \) form a counterexample.

5.7 (a) Observe that \((a + b) \left( \frac{1}{a} + \frac{1}{b} \right) = 2 + \frac{a}{b} + \frac{b}{a} \geq 2 + 2 = 4 \). (b) The converse is true.
442

Answers to Odd-Numbered Section Exercises

5.9 Let \( x = 3 \) and \( n = 2 \). Then \( x^n + (x + 1)^n = 3^2 + 4^2 = 25 = 5^2 = (x + 2)^n \). Then \( x = 3, n = 2 \) is a counterexample.

5.11 If \( \{n_1, n_2, n_3\} = \{1, 2, 3\} \), then \( 2^n_1 + 2^n_2 + 2^n_3 = 2 + 4 + 8 = 14 \) and \( 3 \mid 14 \). Thus, \( \{n_1, n_2, n_3\} = \{1, 2, 3\} \) is a counterexample.

Section 5.2: Proof by Contradiction

5.13 Assume, to the contrary, that there exists a smallest positive irrational number \( r \). Then \( r/2 \) is a positive irrational number and \( r/2 < r \).

5.15 Let \( a \) and \( b \) be odd integers and assume, to the contrary, that \( 4 \mid (a^2 + b^2) \). Then \( a^2 + b^2 = 4x \) for some integer \( x \). Starting with this, a contradiction can be obtained.

5.17 Assume, to the contrary, that 1000 can be expressed as the sum of three integers \( a, b \), and \( c \), an even number of which are even. There are two cases.

Case 1. None of \( a, b \), and \( c \) is even. Then \( a = 2x + 1, b = 2y + 1 \) and \( c = 2z + 1 \), where \( x, y, z \in \mathbb{Z} \). Thus,

\[
1000 = (2x + 1) + (2y + 1) + (2z + 1) = 2(x + y + z + 1) + 1.
\]

Since \( x + y + z + 1 \) is an integer, 1000 is odd, which is a contradiction.

Case 2. Exactly two of \( a, b \), and \( c \) are even, say \( a \) and \( b \) are even and \( c \) is odd. (The argument is similar to that in Case 1.)

5.19 \textbf{Proof} Assume, to the contrary, that there exist an irrational number \( a \) and a nonzero rational number \( b \) such that \( a/b \) is a rational number. Then \( a/b = p/q \), where \( p, q \in \mathbb{Z} \) and \( p, q \neq 0 \). Since \( b \) is a nonzero rational number, \( b = r/s \), where \( r, s \in \mathbb{Z} \) and \( r, s \neq 0 \). Thus, \( a = (bp)/q = (rp)/(sq) \). Since \( r, s \in \mathbb{Z} \) and \( s \neq 0 \), it follows that \( a \) is a rational number, which is a contradiction.

5.21 \textbf{Proof} Assume to the contrary, that \( \sqrt{3} \) is rational. Then \( \sqrt{3} = p/q \), where \( p, q \in \mathbb{Z} \) and \( q \neq 0 \). We may assume that \( p/q \) has been reduced to lowest terms. Thus, \( 3 = p^2/q^2 \) and so \( p^2 = 3q^2 \). Since \( 3 \mid p^2 \), it follows that \( 3 \mid p \). Thus, \( p = 3x \) for some integer \( x \). Therefore, \( p^2 = (3x)^2 = 9x^2 = 3q^2 \). So \( 3x^2 = q^2 \). Since \( x^2 \) is an integer, \( 3 \mid q^2 \). Thus, \( 3 \mid q \) and so \( q = 3y \), where \( y \in \mathbb{Z} \). Hence, \( p = 3x \) and \( q = 3y \), which contradicts our assumption that \( p/q \) has been reduced to lowest terms.

5.23 (a) One possible way to prove this is to use the fact that for integers \( a \) and \( b \), the product \( ab \) is even if and only if \( a \) is even or \( b \) is even.

\textbf{Proof} Assume, to the contrary, that \( \sqrt{6} \) is rational. Then \( \sqrt{6} = a/b \) for nonzero integers \( a \) and \( b \). We can further assume that \( a/b \) has been reduced to lowest terms. Thus, \( 6 = a^2/b^2 \); so \( a^2 = 6b^2 = 2(3b^2) \). Because \( 3b^2 \) is an integer, \( a^2 \) is even. By Theorem 3.12, \( a \) is even. So, \( a = 2c \), where \( c \in \mathbb{Z} \). Thus, \( (2c)^2 = 6b^2 \) and so \( 4c^2 = 6b^2 \). Therefore, \( 3b^2 = 2c^2 \). Because \( c^2 \) is an integer, \( 3b^2 \) is even. By Theorem 3.17, \( 3b^2 = 2c^2 \) is even. Since \( 3 \) is not even, \( b^2 \) is even and so \( b \) is even by Theorem 3.12. However, since \( a \) and \( b \) are both even, each has 2 as a divisor, contradicting the fact that \( a/b \) has been reduced to lowest terms.

(b) We can use an argument similar to that employed in (a) to prove that \( \sqrt{2k} \) is irrational for every odd positive integer \( k \).

5.25 \textbf{Proof} Assume to the contrary, that there is some integer \( a \) such that \( a \equiv 5 \) (mod 14) and \( a \equiv 3 \) (mod 21). Then 14 \mid (a - 5) and 21 \mid (a - 3); so \( a = 5 + 14x \) and \( a = 3 + 21y \) for some integers \( x \) and \( y \). Therefore, \( 5 + 14x = 3 + 21y \), which implies that \( 2 = 21y - 14x = 7(3y - 2x) \). Since \( 3y - 2x \) is an integer, \( 7 \mid 2 \), which is a contradiction.

5.27 \textbf{Proof} Suppose that there exist three distinct positive integers \( a, b \), and \( c \) such that each divides the difference of the other two. We may assume that \( a < b < c \). Thus, \( c \mid (b - a) \). Since \( 0 < b - a < c \), this is a contradiction.

5.29 \textbf{Proof} Assume, to the contrary, that there exist positive real numbers \( x \) and \( y \) such that \( \sqrt{x + y} = \sqrt{x} + \sqrt{y} \). Squaring both sides, we obtain \( x + y = x + 2\sqrt{xy} + y \) and so \( 2\sqrt{xy} = 2\sqrt{xy} = 0 \). This implies that \( xy = 0 \). Thus, \( x = 0 \) or \( y = 0 \), which is a contradiction.

5.31 Assume, to the contrary, that there exist positive integers \( x \) and \( y \) such that \( x^2 - y^2 = m = 2s \). Then \( (x + y)(x - y) = 2s \), where \( s \) is an odd integer. We consider two cases, according to whether \( x \) and \( y \) are of the same parity or of opposite parity. Note that if \( x \) and \( y \) are of the same parity, then both \( x + y \) and \( x - y \) are even, while if \( x \) and \( y \) are of opposite parity, then both \( x + y \) and \( x - y \) are odd. Produce a contradiction in each case.
5.33 Proof Suppose that $5 \mid xy$ and assume, to the contrary, that $5 \mid x$ or $5 \mid y$, say the former. Then $x = 5a$ for some integer $a$. Thus, $xy = (5a)y = 5(ay)$. Since $ay$ is an integer, $5 \mid xy$, contradicting the assumption that $5 \nmid xy$. ■

5.35 (a) Proof Assume, to the contrary, that $x^2 - 3x + 1 = 0$ has a rational number solution $p/q$, where $p, q \in \mathbb{Z}$ and $q \neq 0$. We may assume that $p/q$ is expressed in lowest terms. Thus, $\frac{p}{q}^2 - \frac{3p}{q} + 1 = 0$ and so $p^2 - 3pq + q^2 = 0$. We consider two cases.

Case 1. Exactly one of $p$ and $q$ is even, say $p$ is even and $q$ is odd. Then $p = 2r$ and $q = 2s + 1$, where $r, s \in \mathbb{Z}$. Hence,

$$p^2 - 3pq + q^2 = (2r)^2 - 3(2r)(2s + 1) + (2s + 1)^2$$

$$= 4r^2 - 12rs - 6r + 4s^2 + 4s + 1$$

$$= 2(2r^2 - 6rs - 3r + 2s^2 + 2s) + 1 = 0.$$

Since $2r^2 - 6rs - 3r + 2s^2 + 2s \in \mathbb{Z}$, it follows that $p^2 - 3pq + q^2$ is odd and equals 0, which is a contradiction.

Case 2. Both $p$ and $q$ are odd. (The proof in this case is similar to the proof of Case 1.) ■

(b) For positive integers $k$ and $n$ with $k < n$ and odd integers $a, b$ and $c$, the equation $ax^k + bx^k + c = 0$ has no rational number solution.

Section 5.3: A Review of Three Proof Techniques

5.37 (a) Proof Assume that $x - \frac{2}{7} > 1$. Since $x > 0$, it follows, by multiplying by $x$, that $x^2 - 2 > x$ and so $x^2 - x - 2 > 0$. Hence, $(x - 2)(x + 1) > 0$. Dividing by the positive number $x + 1$, we have $x - 2 > 0$ and so $x > 2$. ■

(b) Proof Assume that $0 < x \leq 2$. Thus, $x^2 - x - 2 = (x - 2)(x + 1) \leq 0$ and so $x^2 - 2 \leq x$. Dividing by the positive number $x$, we have $x - \frac{2}{x} \leq 1$. ■

(c) Proof Assume, to the contrary, that there exists a positive number $x$ such that $x - \frac{2}{7} > 1$ and $x \leq 2$. Thus, $x^2 - x - 2 = (x - 2)(x + 1) \leq 0$ and so $x^2 - 2 \leq x$. Dividing by the positive number $x$, we have $x - \frac{2}{x} \leq 1$, producing a contradiction. ■

5.39 (a) Proof Let $x, y \in \mathbb{R}^+$ such that $x \leq y$. Multiplying both sides by $x$ and $y$, respectively, we obtain $x^2 \leq xy$ and $xy \leq y^2$. Therefore, $x^2 \leq xy \leq y^2$ and so $x^2 \leq y^2$.

(b) Proof Assume that $x^2 > y^2$. Thus, $x^2 - y^2 > 0$ and so $(x + y)(x - y) > 0$. Dividing by the positive number $x + y$, we obtain $x - y > 0$ and $x > y$. ■

(c) Proof Assume, to the contrary, that there exist positive numbers $x$ and $y$ such that $x \leq y$ and $x^2 > y^2$. Since $x \leq y$, it follows that $x^2 \leq xy$ and $xy \leq y^2$. Thus, $x^2 \leq y^2$, producing a contradiction. ■

5.41 Proof (Direct Proof) Let $a, b, c \in \mathbb{Z}$. We show that exactly two of $ab, ac$ and $bc$ cannot be odd. If all of $a, b$ and $c$ are odd, then $ab, ac$ and $bc$ are all odd; otherwise, at least one of $a, b$ and $c$ is even, say $a$ is even. Then $ab$ and $ac$ are even.

Proof (Proof by Contradiction) Let $a, b, c \in \mathbb{Z}$ and assume, to the contrary, that exactly two of $ab, ac$ and $bc$ are odd, say $ab$ and $ac$ are odd. Then $a, b$ and $c$ are odd, which implies that $bc$ is odd, a contradiction. ■

Section 5.4: Existence Proofs

5.43 Proof Consider the rational number 2 and the irrational number $\frac{1}{\sqrt{5}}$. If $2^{\frac{1}{\sqrt{5}}}$ is irrational, then $a = 2$ and $b = \frac{1}{\sqrt{5}}$ have the desired properties. If, on the other hand, $2^{\frac{1}{\sqrt{5}}} = \frac{1}{\sqrt{5}}$ is rational, then

$$\left(2^{\frac{1}{\sqrt{5}}}\right)^\sqrt{5} = 2^{\frac{1}{\sqrt{5}}} = 2^{\frac{1}{2}} = \sqrt{2}$$

is irrational and so $a = 2^{\frac{1}{\sqrt{5}}}$ and $b = \sqrt{2}$ have the desired properties. ■

Exercises for Chapter 5
Answers to Odd-Numbered Section Exercises

5.45 Proof Assume, to the contrary, that there exist nonzero real numbers $a$ and $b$ such that $\sqrt{a^2 + b^2} = \frac{3}{2}a + b^2$. Raising both sides to the 6th power, we obtain

$$a^6 + 3a^4b^2 + 3a^2b^4 + b^6 = a^6 + 2a^3b^3 + b^6.$$ 

Thus,

$$3a^2 - 2ab + 3b^2 = (a - b)^2 + 2a^2 + 2b^2 = 0.$$ 

Since this can only occur when $a = b = 0$, we have a contradiction. ■

5.47 Let $W = S - T$. Since $T$ is a proper subset of $S$, it follows that $\emptyset \neq W \subseteq S$. Then $R(x)$ is true for every $x \in W$, that is, $\forall x \in W, R(x)$ is true.

5.49 Proof Suppose that $S = \{a, b, c\}$. The nonempty subsets of $S$ are $\{a\}, \{b\}, \{c\}, \{a, b\}, \{a, c\}, \{b, c\}$ and $\{a, b, c\}$. For each such subset $A$ of $S$, $\sigma_A$ is congruent to 0, 1, 2, 3, 4 or 5 modulo 6. Since there are seven nonempty subsets of $S$, there must be two of these seven subsets, say $B$ and $C$, such that $\sigma_B \equiv \sigma_C$ (mod 6). ■

5.51 Proof Let $n \in \mathbb{Z}$ with $n \geq 8$. Then $n = 3q$ where $q \geq 3$, $n = 3q + 1$ where $q \geq 3$ or $n = 3q + 2$ where $q \geq 2$.

We consider these three cases.

Case 1. $n = 3q$, where $q \geq 3$. Then $n = 3a + 5b$, where $a = q \geq 3$ and $b = 0$.

Case 2. $n = 3q + 1$, where $q \geq 3$. Then $n = 3(q - 3) + 10$, where $q - 3 \geq 0$. Thus, $n = 3a + 5b$, where $a = q - 3 \geq 0$ and $b = 2$.

Case 3. $n = 3q + 2$, where $q \geq 2$. Then $n = 3(q - 1) + 5$, where $q - 1 \geq 1$. Thus, $n = 3a + 5b$, where $a = q - 1 \geq 1$ and $b = 1$.

5.53 Let $S = \{7, 13, 17, 23\}$.

Section 5.5: Disproving Existence Statements

5.55 We show that if $a$ and $b$ are odd integers, then $4 \nmid (3a^2 + 7b^2)$. Let $a$ and $b$ be odd integers. Then $a = 2x + 1$ and $b = 2y + 1$ for integers $x$ and $y$. Then $3a^2 + 7b^2 = 4(3x^2 + 3y^2 + 7y + 2) + 2$. Since 2 is the remainder when $3a^2 + 7b^2$ is divided by 4, it follows that $4 \nmid (3a^2 + 7b^2)$.

5.57 Show that if $n$ is an integer, then $n^3 + n^3 + n^2 + n$ is even. Let $n \in \mathbb{Z}$. Then $n$ is even or $n$ is odd. We consider these two cases.

Case 1. $n$ is even. Then $n = 2a$ for some integer $a$. Then

$$n^2 + n^3 + n^2 + n = n(n + 1)(n^2 + 1) = 2a(n + 1)(n^2 + 1) = 2[a(n + 1)(n^2 + 1)].$$

Since $a(n + 1)(n^2 + 1)$ is an integer, $n^2 + n^3 + n^2 + n$ is even.

Case 2. $n$ is odd. (The argument is similar here.)

5.59. Proof Assume, to the contrary, that there exists a positive integer $m$ such that $\forall n \in (m, \infty)$, $P(n)$ is true. Thus, $P(n)$ is true for each integer $n > m$. Since $\forall n \in \mathbb{N}$, $P(n)$ has an infinite number of counterexamples, there is a counterexample $k$ such that $k > m$. However then, $k \in (m, \infty)$ and $P(k)$ is false, which is a contradiction. ■

EXERCISES FOR CHAPTER 6

Section 6.1: The Principle of Mathematical Induction

6.1 The sets in (b) and (d) are well-ordered.

6.3 Proof Let $S$ be a nonempty set of negative integers. Let $T = \{n : -n \in S\}$. Hence, $T$ is a nonempty set of positive integers. By the Well-Ordering Principle, $T$ has a least element $m$. Hence, $m \leq n$ for all $n \in T$.

Therefore, $-m \in S$ and $-m \geq -n$ for all $-n \in S$. Thus, $-m$ is the largest element of $S$. ■

6.5 Proof We use induction. Since $1 = 2 \cdot 1^2 - 1$, the formula holds for $n = 1$. Assume that the formula holds for some integer $k \geq 1$, that is,

$$1 + 5 + 9 + \cdots + (4k - 3) = 2k^2 - k.$$ 

We show that

$$1 + 5 + 9 + \cdots + [4(k + 1) - 3] = 2(k + 1)^2 - (k + 1).$$
Observe that
\[ 1 + 5 + 9 + \cdots + [4(k + 1) - 3] = [1 + 5 + 9 + \cdots + (4k - 3)] + 4(k + 1) - 3 \\
= (2k^2 - k) + (4k + 1) = 2k^2 + 3k + 1 \\
= 2(k + 1)^2 - (k + 1). \]

The result then follows by the Principle of Mathematical Induction.

\[ \text{6.7 One possibility: } 1 + 7 + 13 + \cdots + (6n - 5) = 3n^2 - 2n \text{ for every positive integer } n. \]

\[ \text{6.9 Proof } \text{ We proceed by induction. For } n = 1, \text{ we have } 1 \cdot 3 = \frac{1 + 1 + 2 + \cdots + 7}{6}, \text{ which is true. Assume that} \]
\[ 1 \cdot 3 + 2 \cdot 4 + 3 \cdot 5 + \cdots + k(k + 2) = \frac{4(k + 1)(2k + 7)}{6} \text{ where } k \in \mathbb{N}. \]
We then show that
\[ 1 \cdot 3 + 2 \cdot 4 + 3 \cdot 5 + \cdots + (k + 1)(k + 3) = \frac{(k + 1)(k + 2)(2k + 9)}{6}. \]

Observe that
\[ 1 \cdot 3 + 2 \cdot 4 + 3 \cdot 5 + \cdots + (k + 1)(k + 3) \\
= [1 \cdot 3 + 2 \cdot 4 + 3 \cdot 5 + \cdots + k(k + 2)] + (k + 1)(k + 3) \\
= \frac{k(k + 1)(2k + 7)}{6} + (k + 1)(k + 3) \\
= \frac{k(k + 1)(2k + 7) + 6(k + 1)(k + 3)}{6} \\
= \frac{(k + 1)(2k^2 + 7k + 6k + 18)}{6} = \frac{(k + 1)(2k^2 + 13k + 18)}{6} \\
= \frac{(k + 1)(k + 2)(2k + 9)}{6}. \]

By the Principle of Mathematical Induction,
\[ 1 \cdot 3 + 2 \cdot 4 + 3 \cdot 5 + \cdots + n(n + 2) = \frac{n(n + 1)(2n + 7)}{6} \]
for every positive integer \( n \).

\[ \text{6.11 We proceed by induction. Since } \frac{1}{3^4} = \frac{1}{3^4}, \text{ the formula holds for } n = 1. \text{ Assume that} \]
\[ \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \cdots + \frac{1}{(k + 2)(k + 3)} = \frac{k}{3k + 9} \]
where \( k \) is a positive integer. Then show that
\[ \frac{1}{3 \cdot 4} + \frac{1}{4 \cdot 5} + \cdots + \frac{1}{(k + 3)(k + 4)} + \frac{1}{(k + 3)(k + 4)} = \frac{k + 1}{3(k + 1) + 9} = \frac{k + 1}{3(k + 4)}. \]

\[ \text{6.13 Proof } \text{ We proceed by induction. Since } 1 \cdot 1! = 2! - 1, \text{ the statement is true for } n = 1. \text{ Assume that} \]
\[ 1 \cdot 1! + 2 \cdot 2! + \cdots + k \cdot k! = (k + 1)! - 1, \]
where \( k \in \mathbb{N}. \text{ We show that} \]
\[ 1 \cdot 1! + 2 \cdot 2! + \cdots + (k + 1) \cdot (k + 1)! = (k + 2)! - 1. \]

Now
\[ 1 \cdot 1! + 2 \cdot 2! + \cdots + (k + 1) \cdot (k + 1)! = (1 \cdot 1! + 2 \cdot 2! + \cdots + k \cdot k!) + (k + 1) \cdot (k + 1)! \\
= (k + 1)! - 1 + (k + 1) \cdot (k + 1)! \\
= (k + 1)!(k + 2) - 1 = (k + 2)! - 1. \]

By the Principle of Mathematical Induction, \( 1 \cdot 1! + 2 \cdot 2! + \cdots + n \cdot n! = (n + 1)! - 1 \) for all \( n \in \mathbb{N}. \)
6.15 Proof We proceed by induction. Since $\frac{1}{\sqrt{1}} \leq 2\sqrt{1} - 1$, the inequality holds for $n = 1$. Assume that
$$\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{k}} \leq 2\sqrt{k} - 1$$
for a positive integer $k$. We show that
$$\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{k+1}} \leq 2\sqrt{k+1} - 1.$$ 
Observe that
$$\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{k+1}} = \left(\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{k}}\right) + \frac{1}{\sqrt{k+1}}$$
$$\leq (2\sqrt{k} - 1) + \frac{1}{\sqrt{k+1}} = \frac{2\sqrt{k^2+k+1}}{\sqrt{k+1}} - 1.$$ 
Since $4(k^2+k) \leq (2k+1)^2$, it follows that $2\sqrt{k^2+k} \leq 2k+1$ and so $2\sqrt{k^2+k+1} \leq 2(k+1) = 2(\sqrt{k+1})^2$. Therefore,
$$\frac{2\sqrt{k^2+k+1}}{\sqrt{k+1}} \leq 2\sqrt{k+1}.$$ 
Thus,
$$\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{k+1}} \leq 2\sqrt{k+1} - 1.$$ 
By the Principle of Mathematical Induction, $\frac{1}{\sqrt{1}} + \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{3}} + \cdots + \frac{1}{\sqrt{n}} \leq 2\sqrt{n} - 1$ for every positive integer $n$. ■

Section 6.2: A More General Principle of Mathematical Induction

6.17 Proof We need only show that every nonempty subset of $S$ has a least element. So, let $T$ be a nonempty subset of $S$. If $T$ is a subset of $N$, then, by the Well-Ordering Principle, $T$ has a least element. Hence, we may assume that $T$ is not a subset of $N$. Thus, $T - N$ is a finite nonempty set and so contains a least element $t$. Since $t \leq 0$, it follows that $t \leq x$ for all $x \in T$; so $t$ is a least element of $T$. ■

6.19 Proof We use induction. We know that if $a$ and $b$ are two real numbers such that $ab = 0$, then $a = 0$ or $b = 0$. Thus, the statement is true for $n = 2$. Assume that:

If $a_1, a_2, \ldots, a_k$ are any $k \geq 2$ real numbers whose product is 0, then $a_i = 0$ for some integer $i$ with $1 \leq i \leq k$.

We wish to show the statement is true in the case of $k + 1$ numbers, that is:

If $b_1, b_2, \ldots, b_{k+1}$ are $k + 1$ real numbers such that $b_1b_2 \cdots b_{k+1} = 0$, then $b_i = 0$ for some integer $i$ ($1 \leq i \leq k + 1$).

Let $b_1, b_2, \ldots, b_{k+1}$ be $k + 1$ real numbers such that $b_1b_2 \cdots b_{k+1} = 0$. We show that $b_i = 0$ for some integer $i$ ($1 \leq i \leq k + 1$). Let $b = b_1b_2 \cdots b_k$. Then
$$b_1b_2 \cdots b_{k+1} = (b_1b_2 \cdots b_k)b_{k+1} = bb_{k+1} = 0.$$ 
Therefore, either $b = 0$ or $b_{k+1} = 0$. If $b_{k+1} = 0$, then we have the desired conclusion. On the other hand, if $b = b_1b_2 \cdots b_k = 0$, then, since $b$ is the product of $k$ real numbers, it follows by the inductive hypothesis that $b_i = 0$ for some integer $i$ ($1 \leq i \leq k$). In any case, $b_i = 0$ for some integer $i$ ($1 \leq i \leq k + 1$). The result then follows by the Principle of Mathematical Induction. ■
6.21 \textbf{Proof} \ We proceed by induction. Since \(4 \mid (5^0 - 1)\), the statement is true for \(n = 0\). Assume that \(4 \mid (5^k - 1)\), where \(k\) is a nonnegative integer. We show that \(4 \mid (5^{k+1} - 1)\). Since \(4 \mid (5^k - 1)\), it follows that \(5^k = 4a + 1\) for some integer \(a\). Observe that

\[5^{k+1} - 1 = 5 \cdot 5^k - 1 = 5(4a + 1) - 1 = 20a + 4 = 4(5a + 1).\]

Since \((5a + 1) \in \mathbb{Z}\), it follows that \(4 \mid (5^{k+1} - 1)\). By the Principle of Mathematical Induction, \(4 \mid (5^n - 1)\) for every nonnegative integer \(n\).

6.23 We employ mathematical induction. For \(n = 0\), we have \(7 \mid 0\), which is true. Assume that \(7 \mid (3^k - 2^k)\) for some integer \(k \geq 0\). We show that \(7 \mid (3^{2k+1} - 2^{2k+1})\). Since \(7 \mid (3^2 - 2^2)\), it follows that \(3^2 - 2^2 = 7a\) for some integer \(a\). Thus, \(3^2k = 2^k + 7a\). Then show that \(3^{2(k+1)} - 2^{2(k+1)} = 7(2^k + 9a)\).

6.25 \textbf{Proof} \ We use induction. Since \(4! = 24 > 16 = 2^4\), the inequality holds for \(n = 4\). Suppose that \(k! > 2^k\) for an arbitrary integer \(k \geq 4\). We show that \((k+1)! > 2^{k+1}\). Observe that

\[(k+1)! = (k+1)k! > (k+1)2^k \geq (4+1)2^k = 5 \cdot 2^k > 2 \cdot 2^k = 2^{k+1}.
\]

Therefore, \((k+1)! > 2^{k+1}\). By the Principle of Mathematical Induction, \(n! > 2^n\) for every integer \(n \geq 4\).

6.27 \textbf{Proof} \ We proceed by induction. Since \(1 \leq 2 - \frac{1}{k}\), the inequality holds for \(n = 1\). Assume that \(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{k} \leq 2 - \frac{1}{k}\) for some positive integer \(k\). We show that \(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{k+1} \leq 2 - \frac{1}{k+1}\). Observe that

\[1 + \frac{1}{4} + \frac{1}{9} + \cdots + \frac{1}{(k+1)^2} = \left(1 + \frac{1}{4} + \frac{1}{9} + \cdots + \frac{1}{k^2}\right) + \frac{1}{k+1}^2 \leq 2 + \frac{1}{k} + \frac{1}{(k+1)^2}\]

\[= 2 + \frac{1}{k} + \frac{1}{(k+1)^2} = 2 + \frac{-k + 1}{k(k+1)^2} = 2 - \frac{k^2 + k + 1}{k(k+1)^2} \leq 2 - \frac{1}{k+1}.
\]

By the Principle of Mathematical Induction, \(1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{k} \leq 2 - \frac{1}{k}\) for every positive integer \(k\).

6.29 \textbf{Proof} \ We proceed by induction. By De Morgan’s law, if \(A\) and \(B\) are any two sets, then \(\overline{A \cap B} = \overline{A} \cup \overline{B}\). Hence, the statement is true for \(n = 2\). Assume, for any \(k\) sets \(A_1, A_2, \ldots, A_k\), where \(k \geq 2\), that

\[A_1 \cap A_2 \cap \cdots \cap A_k = \overline{A}_1 \cup \overline{A}_2 \cup \cdots \cup \overline{A}_k.
\]

Now consider any \(k+1\) sets, say \(B_1, B_2, \ldots, B_{k+1}\). We show that

\[B_1 \cap B_2 \cap \cdots \cap B_{k+1} = \overline{B}_1 \cup \overline{B}_2 \cup \cdots \cup \overline{B}_{k+1}.
\]

Let \(B = B_1 \cap B_2 \cap \cdots \cap B_k\). Observe that

\[B_1 \cap B_2 \cap \cdots \cap B_{k+1} = (B_1 \cap B_2 \cap \cdots \cap B_k) \cap B_{k+1} = B \cap B_{k+1}
\]

\[= \overline{B} \cup \overline{B}_{k+1} = (\overline{B}_1 \cup \overline{B}_2 \cup \cdots \cup \overline{B}_k) \cup \overline{B}_{k+1}
\]

\[= B_1 \cup B_2 \cup \cdots \cup B_{k+1}.
\]

The result then follows by the Principle of Mathematical Induction.

6.31 \textbf{Proof} \ We proceed by induction. Since \(a \left(\frac{1}{a}\right) = 1^2\) for every positive real number \(a\), the inequality is true for \(n = 1\). Assume for each \(k\) positive real numbers \(a_1, a_2, \ldots, a_k\) that

\[\left(\sum_{i=1}^{k} a_i\right) \left(\sum_{i=1}^{k} \frac{1}{a_i}\right) \geq k^2.
\]

Let \(b_1, b_2, \ldots, b_{k+1}\) be \(k+1\) positive real numbers. We show that

\[\left(\sum_{i=1}^{k+1} b_i\right) \left(\sum_{i=1}^{k+1} \frac{1}{b_i}\right) \geq (k+1)^2.
\]
448 Answers to Odd-Numbered Section Exercises

Observe that
\[ \left( \sum_{j=1}^{k+1} b_j \right) \left( \sum_{j=1}^{k+1} \frac{1}{b_j} \right) = \left( \sum_{j=1}^{k} b_j \right) \left( \sum_{j=1}^{k} \frac{1}{b_j} \right) + b_{k+1} \left( \sum_{j=1}^{k} \frac{1}{b_j} \right) + \frac{1}{b_{k+1}} \left( \sum_{j=1}^{k} b_j \right) + b_{k+1} \cdot \frac{1}{b_{k+1}} \]
\[ \geq k^2 + \sum_{i=1}^{k} \left( \frac{b_{i+1}}{b_i} + \frac{b_i}{b_{i+1}} \right) + 1. \]

Since \( \frac{b_{i+1}}{b_i} + \frac{b_i}{b_{i+1}} \geq 2 \) (see Exercise 4.78), it follows that
\[ \left( \sum_{j=1}^{k+1} b_j \right) \left( \sum_{j=1}^{k+1} \frac{1}{b_j} \right) \geq k^2 + 2k + 1 = (k+1)^2. \]

By the Principle of Mathematical Induction, \( \left( \sum_{i=1}^{n} a_i \right) \left( \sum_{i=1}^{n} \frac{1}{a_i} \right) \geq n^2 \) for every \( n \) positive real numbers \( a_1, a_2, \ldots, a_n \).

Section 6.3: The Strong Principle of Mathematical Induction

6.33 Conjecture A sequence \( \{a_n\} \) is defined recursively by \( a_1 = 1 \) and \( a_n = 2a_{n-1} \) for \( n \geq 2 \). Then \( a_n = 2^{n-1} \) for all \( n \geq 1 \).

Proof We proceed by mathematical induction. Since \( a_1 = 2^{1-1} = 2^0 = 1 \), it follows that \( a_n = 2^{n-1} \) when \( n = 1 \). Assume that \( a_k = 2^{k-1} \) for some positive integer \( k \). We show that \( a_{k+1} = 2^k \). Since \( k \geq 1 \), it follows that \( k+1 \geq 2 \). Therefore,
\[ a_{k+1} = 2a_k = 2 \cdot 2^{k-1} = 2^k. \]

The result follows by the Principle of Mathematical Induction.

6.35 Conjecture A sequence \( \{a_n\} \) is defined recursively by \( a_1 = 1, a_2 = 4, a_3 = 9 \) and
\[ a_n = a_{n-1} - a_{n-2} + a_{n-3} + 2(2n-3) \]
for \( n \geq 4 \). Then \( a_n = n^2 \) for all \( n \geq 1 \).

Proof We proceed by the Strong Principle of Mathematical Induction. Since \( a_1 = 1^2 = 1 \), it follows that \( a_n = n^2 \) when \( n = 1 \). Assume that \( a_i = i^2 \), where \( 1 \leq i \leq k \) for some positive integer \( k \). We show that \( a_{k+1} = (k+1)^2 \). Since \( a_2 = a_1 + 1 = (1+1)^2 = 4 \) and \( a_3 = a_2 + 1 = (2+1)^2 = 9 \), it follows that \( a_{k+1} = (k+1)^2 \) for \( k = 1, 2 \). Hence, we may assume that \( k \geq 3 \). Since \( k+1 \geq 4 \),
\[ a_{k+1} = a_k - a_{k-1} + a_{k-2} + 2[2(k+1) - 3] \]
\[ = k^2 - (k-1)^2 + (k-2)^2 + (4k-2) \]
\[ = k^2 - 2k + 1 + (k^2 - 4k + 4) + (4k - 2) \]
\[ = k^2 + 2k + 1 = (k+1)^2. \]

The result then follows by the Strong Principle of Mathematical Induction.

6.37 Proof We use the Strong Principle of Mathematical Induction. Since \( 12 = 3 \cdot 4 + 7 \cdot 0 \), the statement is true when \( n = 12 \). Assume for an integer \( k \geq 12 \) that for every integer \( i \) with \( 12 \leq i \leq k \), there exist nonnegative integers \( a \) and \( b \) such that \( i = 3a + 7b \). We show that there exist nonnegative integers \( x \) and \( y \) such that \( k + 1 = 3x + 7y \). Since \( 13 = 3 \cdot 2 + 7 \cdot 1 \) and \( 14 = 3 \cdot 0 + 7 \cdot 2 \), we may assume that \( k \geq 14 \). Since \( k - 2 \geq 12 \), there exist nonnegative integers \( c \) and \( d \) such that \( k - 2 = 3c + 7d \). Hence, \( k + 1 = 3(c+1) + 7d \).

By the Strong Principle of Mathematical Induction, for each integer \( n \geq 12 \), there are nonnegative integers \( a \) and \( b \) such that \( n = 3a + 7b \).

6.39 We show that every odd integer \( n \geq 15 \) can be expressed as \( 3a + 11b \) or as \( 5c + 7d \) for nonnegative integers \( a, b, c \) and \( d \).
Proof We use the Strong Principle of Mathematical Induction. First, observe that 15 = 3 · 5 + 11 · 0 = 5 · 3 + 7 · 0, 17 = 3 · 2 + 11 · 1, 19 = 5 · 1 + 7 · 2, 21 = 3 · 7 + 11 · 0 and 23 = 3 · 4 + 11 · 1. Thus, the statement is true for 15, 17, 19, 21 and 23. Assume that the statement is true for every odd integer i with 15 ≤ i ≤ k, where k ≥ 23 is an odd integer. We show that the statement is true for the integer k + 2. Suppose that k = 3a + 11b for some nonnegative integers a and b. Since k ≥ 23, either a ≥ 3 or b ≥ 2. If a ≥ 3, then k + 2 = 3(a + 1) + 11(b − 2); while if b ≥ 2, then k + 2 = 3(a + 8) + 11(b − 2). Hence, we may assume that k = 5c + 7d for some nonnegative integers c and d. If c ≥ 1, then k + 2 = 5(c − 1) + 7(d + 1). The remaining situation is where c = 0 and so k ≥ 23 is an odd integer multiple of 7. So, k = 7d, where d ≥ 5. In this case, k + 2 = 5 · 6 + 7(d − 4). The result then follows by the Strong Principle of Mathematical Induction.

Section 6.4: Proof by Minimum Counterexample

Proof Assume, to the contrary, that there is a positive integer n such that 1 + 3 + 5 + ⋅⋅⋅ + (2n − 1) ≠ n^2. Let m be the smallest such integer. Since 2 · 1 − 1 = 1^2, it follows that m ≥ 2. Thus, m can be expressed as m = k + 1, where 1 ≤ k < m. Therefore, 1 + 3 + 5 + ⋅⋅⋅ + (2k + 1) = k^2. Then

1 + 3 + 5 + ⋅⋅⋅ + (2m − 1) = 1 + 3 + 5 + ⋅⋅⋅ + (2k + 1)
= [1 + 3 + 5 + ⋅⋅⋅ + (2k − 1)] + (2k + 1)
= k^2 + (2k + 1) = (k + 1)^2 = m^2,

which is a contradiction.

Proof Assume, to the contrary, that there is some nonnegative integer n such that 3 | (2^n + 2^{n+1}). Then there is a smallest nonnegative integer n such that 3 | (2^n + 2^{n+1}). Let m be this integer. Since 2^3 + 2^1 = 3, we have m ≥ 1. So, we can write m = k + 1, where 0 ≤ k < m. Thus, 3 | (2^k + 2^{k+1}) and so 2^k + 2^{k+1} = 3x for some integer x. Then show that 2^m + 2^{m+1} = 3(2x).

Proof Assume, to the contrary, that there is some positive integer n such that 12 | (n^3 − n^2). Then there is a smallest positive integer n such that 12 | (n^3 − n^2). Let m be this integer. It can be shown that if 1 ≤ n ≤ 6, then 12 | (n^3 − n^2). Therefore m ≥ 7. So, we can write m = k + 6, where 1 ≤ k < m. Consider (k + 6)^3 − (k + 6)^2.

Proof Assume, to the contrary, that there is a positive integer n such that 6 | 7n (n^2 − 1). Then there is a smallest positive integer n such that 6 | 7n (n^2 − 1). Let m be this integer. Since 6 | 0 and 6 | 42, it follows that 6 | 7n (n^2 − 1) when n = 1 and n = 2. So, m ≥ 3 and we can write m = k + 2, where 1 ≤ k < m. Consequently, 6 | 7k (k^2 − 1) and so 7k (k^2 − 1) = 6x for some integer x. Then show that 7m (m^2 − 1) = 6(x + 7k^3 + 14k + 7).

Exercises for Chapter 7

7.1 Proof Assume that m is an integer such that 10 | m and 12 | m. Then m = 10c and m = 12d where c, d ∈ Z. Thus, 10c = 12d = 3(4d). Since 4d is an integer, 3 | 10c. By Result 4.8, 3 | 10 or 3 | c. Since 3 | 10, it follows that 3 | c and so c = 3e for some integer e. Therefore, m = 10c = 30e = 12d and so 5e = 2d. Since d is an integer, it follows that 5e is an even integer. Since 5 is odd, it follows by Theorem 3.17 that e is even and so e = 2f for some integer f. Hence, m = 30e = 30(2f) = 60f and so 60 | m.

7.3 (a) Proof Since m is the product of four consecutive integers, we may assume that m = (k − 1)k(k + 1)(k + 2) for some integer k. Thus,

m + 1 = [k(k + 1)][(k − 1)(k + 2)] + 1 = (k^2 + k)(k^2 + k − 2) + 1
= (k^2 + k)^2 − 2(k^2 + k) + 1 = (k^2 + k − 1)^2.

[Note: Although m could be expressed as k(k + 1)(k + 2)(k + 3) for some integer k, writing m = (k − 1)k(k + 1)(k + 2) simplifies the algebra.]

(b) Proof Since n^2 < n(n + 1) < (n + 1)^2 and n^2 < n(n + 2) < (n + 1)^2, neither n(n + 1) nor n(n + 2) is a perfect square.

[Note: For n = 1, however, n(n + 3) = 1 · 4 = 2^2.]
450 Answers to Odd-Numbered Section Exercises

(e) **Proof** For an integer \( m \), either \( m \) or \( m + 1 \) is even and so \( 2 \mid m(m + 1) \). Since 3 divides one of \( m, m + 1 \) and \( m + 2 \), it follows that \( 3 \mid m(m + 1)(m + 2) \). Thus, \( m(m + 1)(m + 2) = 3k \) for some \( k \in \mathbb{Z} \). Since \( 2 \mid 3k \) and \( 2 \mid 3 \), it follows that \( 2 \mid k \) and so \( k = 2\ell \) for some integer \( \ell \). Hence, \( m(m + 1)(m + 2) = 3k = 6\ell \). The product \( 3 \cdot 4 \cdot 5 = 60 \) is not divisible by 9. If \( m \) is even, then \( m + 2 \) is even and so \( m(m + 1)(m + 2) \) is a multiple of 12. If \( m + 1 \) is a multiple of 4, then \( m(m + 1)(m + 2) \) is a multiple of 12. If, however, \( m + 1 \) is even but not a multiple of 4, then \( m + 1 = 4k + 2 \) for some integer \( k \). Hence, \( m(m + 1)(m + 2) = 2\ell \) for some odd integer \( \ell \) and \( m(m + 1)(m + 2) \) is not a multiple of 12 in this case. Therefore, \( m(m + 1)(m + 2) \) is a multiple of 12 if and only if \( m + 1 \neq 4k + 2 \) for any integer \( k \). ■

7.11 (a) **Proof** Let \( a \geq 3 \) be an odd integer. Then \( a = 2n + 1 \) for some positive integer \( n \). We seek a positive even integer \( b \) such that \( (a, b, b + 1) \) is a Pythagorean triple. Then

\[ a^2 + b^2 = 4n^2 + 4n + 1 + b^2 = b^2 + 2b + 1. \]

Therefore, \( 2b = 4n^2 + 4n \) and so \( b = 2n^2 + 2n \). Letting \( b = 2n^2 + 2n \), we see that \( a^2 + b^2 = (b + 1)^2 \) and so \( (a, b, b + 1) \) is a Pythagorean triple. ■
(b) Proof We proceed by induction on $n$. By (a), the statement is true for $n = 1$. Assume for a positive integer $k$ that there exist $k$ positive even integers $b_1, b_2, \ldots, b_k$ such that
\[ a^2 + b_1^2 + b_2^2 + \cdots + b_k^2 = d^2 \]
for some positive integer $d$. Since $a$ is odd and $b_1, b_2, \ldots, b_k$ are even, $d$ is odd. By (a), there exists an even integer $b_{k+1}$ such that $d^2 + b_{k+1}^2 = c^2$ where $c = b_{k+1} + 1$. Therefore,
\[ a^2 + b_1^2 + b_2^2 + \cdots + b_k^2 + b_{k+1}^2 = d^2 + b_{k+1}^2 = c^2. \]

The result then follows by the Principle of Mathematical Induction.

7.13 Proof Assume, to the contrary, that an odd number of the integers $a + b$, $a + c$, and $b + c$ are odd. Then $(a + b) + (a + c) + (b + c)$ is odd. However, $(a + b) + (a + c) + (b + c) = 2(a + b + c)$. Since $a + b + c$ is an integer, $(a + b) + (a + c) + (b + c)$ is even, which is a contradiction.

7.15 Proof Evaluation This proposed proof by contradiction is incorrect. To begin a proof by contradiction, we should begin a proof by assuming that $x, y, z \in \mathbb{Z}$ such that $3x + 5y = 7z$ and at least one of $x$, $y$ and $z$ is odd but none of $x$, $y$ and $z$ is even. Then all of $x$, $y$ and $z$ are odd. In this case, $x = 2a + 1$, $y = 2b + 1$ and $z = 2c + 1$ for $a, b, c \in \mathbb{Z}$. Then
\[ 3x + 5y = 3(2a + 1) + 5(2b + 1) = 6a + 10b + 8 \]
= $2(3a + 5b + 4)$
and
\[ 7z = 7(2c + 1) = 14c + 7 = 2(7c + 3) + 1. \]
Since $3a + 5b + 4$ and $7c + 3$ are integers, $3x + 5y$ is even and $7z$ is odd. Hence, $3x + 5y \neq 7z$, which is a contradiction.

7.17 Proof Evaluation Strictly speaking, the proposed proof is not a proof by contradiction as it was never stated in the proof that $a \notin S$. What was shown instead was that if $\log_2 a$ is rational, then $a \in S$. This is a proof by contrapositive.

7.19 Proof Evaluation The logic is incorrect in the proposed proof. To prove the given statement, which is a biconditional, the following two implications must be verified.
(1) If $ab + ac + bc$ is even, then at most one of $a$, $b$ and $c$ is odd.
(2) If at most one of $a$, $b$ and $c$ is odd, then $ab + ac + bc$ is even.
A proof of (1) can be accomplished by means of a proof by contrapositive. To do this, we show: If at least two of $a$, $b$ and $c$ are odd, then $ab + ac + bc$ is odd. The arguments employed in Cases 3 and 4 in the proposed proof will verify this. A proof of (2) can be accomplished by means of a direct proof using two cases, namely Cases 1 and 2.

7.21 Proof First, suppose that $A \times B = B \times A$. We show that $\mathcal{P}(A) = \mathcal{P}(B)$. Let $X \in \mathcal{P}(A)$. Then $X \subseteq A$. We show that $X \subseteq B$. Let $x \in X$. Then $x \in A$. Since $A \times B = B \times A$, it follows that $x \in B$. Thus, $X \subseteq B$ and so $\mathcal{P}(A) \subseteq \mathcal{P}(B)$. Similarly, $\mathcal{P}(B) \subseteq \mathcal{P}(A)$. Therefore, $\mathcal{P}(A) = \mathcal{P}(B)$. For the converse, assume that $\mathcal{P}(A) = \mathcal{P}(B)$. We show that $A \times B = B \times A$. Let $(x, y) \in A \times B$. Thus, $x \in A$ and $y \in B$. Hence, $\{x\} \in \mathcal{P}(A)$ and $\{y\} \in \mathcal{P}(B)$. Since $\mathcal{P}(A) = \mathcal{P}(B)$, it follows that $\{x\} \in \mathcal{P}(B)$ and $\{y\} \in \mathcal{P}(A)$. Therefore, $x \in B$ and $y \in A$ and so $(x, y) \in B \times A$. Thus, $A \times B \subseteq B \times A$. Similarly, $B \times A \subseteq A \times B$ and so $A \times B = B \times A$.

7.23 Proof Suppose that $r$ is a root of a polynomial with integer coefficients, say
\[ p(x) = a_nx^n + a_{n-1}x^{n-1} + \cdots + a_1x + a_0, \]
where $a_i \in \mathbb{Z}$ for $0 \leq i \leq n$. Then
\[ p(r) = a_nr^n + a_{n-1}r^{n-1} + \cdots + a_1r + a_0 = 0. \]
Therefore,
\[ 2^n(a_nr^n + a_{n-1}r^{n-1} + \cdots + a_1r + a_0) = a_n(2r)^n + 2a_{n-1}(2r)^{n-1} + \cdots + 2^{n-1}a_1(2r) + 2^n a_0 = 0. \]
Answers to Odd-Numbered Section Exercises

Hence, \(2r\) is a root of the polynomial
\[ q(x) = a_nx^n + 2a_{n-1}x^{n-1} + \cdots + 2^{n-1}a_1x + 2^na_0, \]
where each coefficient is an integer.

7.25 First, we verify the following lemma.

**Lemma** For every nonnegative integer \(n\), \(5^{2n} \equiv 2^{2n} \pmod{21}\).

**(Proof)** We proceed by induction. Since \(5^0 \equiv 2^0 \pmod{21}\), the statement is true when \(n = 0\). Assume that \(5^{2k} \equiv 2^{2k} \pmod{21}\) for some nonnegative integer \(k\). By Result 4.11, \(5^{2k+1} \equiv 2^{2k} \cdot 2 = 2^{2k+1} \pmod{21}\) and so \(5^{2k+1} \equiv 2^{2(k+1)} \pmod{21}\). By the Principle of Mathematical Induction, \(5^{2n} \equiv 2^{2n} \pmod{21}\) for every nonnegative integer \(n\).

We now verify the result.

**(Proof)** Let \(n\) be a nonnegative integer. Clearly, \(2^{2n} \equiv 2^{2n} \pmod{21}\). By the lemma, \(5^{2n} \equiv 2^{2n} \pmod{21}\). By Result 4.10,
\[ 5^{2n} + 2^{2n} \equiv 2^{2n} + 2^{2n} \pmod{21}. \]
Since \(2^{2n} + 2^{2n} = 2^{2n+1}\), it follows that \(5^{2n} + 2^{2n} \equiv 2^{2n+1} \pmod{21}\).

7.27 **Proof** First, assume that \(m = n(n+1)/2\) for some \(n \in \mathbb{N}\). Then \(8m + 1 = 4n(n+1) + 1 = 4n^2 + 4n + 1 = (2n + 1)^2\), that is, \(8m + 1\) is a perfect square. For the converse, suppose that \(8m + 1\) is a perfect square for some positive integer \(m\). Thus, \(8m + 1 = t^2\) for some \(t \in \mathbb{N}\). Since \(8m + 1\) is odd, \(t^2\) is odd and by (the contrapositive of) Theorem 3.12, \(t\) is odd. So, \(t = 2n + 1\) for some \(n \in \mathbb{N}\). Hence, \(t - 1 = 2n\) and \(t + 1 = 2n + 2\). Thus,
\[ m = \frac{t^2 - 1}{8} = \frac{(t-1)(t+1)}{8} = \frac{2n(2n+2)}{8} = \frac{n(n+1)}{2}. \]

7.29 **Proof** Assume, to the contrary, that there exist two odd integers \(a\) and \(b\) with \(a \not\equiv b \pmod{4}\) such that \(4 \mid (3a + 5b)\). Since \(a\) and \(b\) are odd, each of \(a\) and \(b\) is either congruent to 1 modulo 4 or congruent to 3 modulo 4. However, since \(a \not\equiv b \pmod{4}\), one of these is congruent to 1 modulo 4 and the other is congruent to 3 modulo 4. We consider these two cases.

Case 1. \(a \equiv 1 \pmod{4}\) and \(b \equiv 3 \pmod{4}\). Hence, \(a = 4x + 1\) and \(b = 4y + 3\) for some integers \(x\) and \(y\). Then
\[ 3a + 5b = 3(4x + 1) + 5(4y + 3) = 12x + 20y + 18 = 4(3x + 5y + 4) + 2. \]
Since \(3a + 5b \equiv 2 \pmod{4}\), it follows that \(4 \nmid (3a + 5b)\), which is a contradiction.

Case 2. \(a \equiv 3 \pmod{4}\) and \(b \equiv 1 \pmod{4}\). Hence, \(a = 4w + 3\) and \(b = 4z + 1\) for some integers \(w\) and \(z\). Then
\[ 3a + 5b = 3(4w + 3) + 5(4z + 1) = 12w + 20z + 5 = 4(3w + 5z + 3) + 2. \]
Since \(3a + 5b \equiv 2 \pmod{4}\), it follows that \(4 \nmid (3a + 5b)\), a contradiction.

7.31 (a) **Proof** The integer \(a = 9,768,345,120\) has the desired properties.

(b) **Proof** The integer \(b = 3,816,547,290\) has the desired properties.

(e) **Proof** Yes, \(m = 48360\).

[Note: This suggests the question of whether there is a 6-digit number with distinct digits having corresponding properties.]

7.33 **Proof** First, assume that either every two integers in \(\{a, b, c\}\) are congruent modulo 3 or no two integers in \(\{a, b, c\}\) are congruent modulo 3. We consider these two cases.

Case 1. Every two integers in \(\{a, b, c\}\) are congruent modulo 3. Thus, \(a = 3k_1 + r, b = 3k_2 + r\) and \(c = 3k_3 + r\) for integers \(k_1, k_2, k_3\) and \(r \in \{0, 1, 2\}\). Hence,
\[ a + b + c = (3k_1 + r) + (3k_2 + r) + (3k_3 + r) = 3(k_1 + k_2 + k_3 + r). \]
Since \(k_1 + k_2 + k_3 + r \in \mathbb{Z}\), it follows that \(a + b + c \equiv 0 \pmod{3}\).
Case 2. No two integers in \{a, b, c\} are congruent modulo 3. Hence, we may assume that \(a = 3k_1, b = 3k_2 + 1\) and \(c = 3k_3 + 2\), where \(k_1, k_2, k_3 \in \mathbb{Z}\). Hence,

\[a + b + c = (3k_1) + (3k_2 + 1) + (3k_3 + 2) = 3(k_1 + k_2 + k_3 + 1).
\]

Since \(k_1 + k_2 + k_3 + 1 \in \mathbb{Z}\), it follows that \(a + b + c \equiv 0 \pmod{3}\).

For the converse, suppose that it is not the case that every two integers in \{a, b, c\} are congruent modulo 3 or every two integers in \{a, b, c\} are not congruent modulo 3. Thus, exactly two integers in \{a, b, c\} are congruent modulo 3, say

\[a \equiv b \pmod{3}, a \not\equiv c \pmod{3} \text{ and } b \not\equiv c \pmod{3}.
\]

Hence, there are integers \(x, y, z, r, s\), where \(r, s \in \{0, 1, 2\}\) and \(s \neq r\), such that \(a = 3x + r, b = 3y + r\) and \(c = 3z + s\). Thus,

\[a + b + c = (3x + r) + (3y + r) + (3z + s) = 3(x + y + z + r) + (s - r).
\]

Since \(x + y + z + r \in \mathbb{Z}\) and \(s - r \in \{-2, -1, 1, 2\}\), it follows that \(a + b + c \not\equiv 0 \pmod{3}\). 

**7.35 Proof** We proceed by induction. Since \(4! = 24 > 16 = 4^2\), the inequality holds for \(n = 4\). Assume that \(k! > k^2\) for an integer \(k \geq 4\). Next, we show that \((k + 1)! > (k + 1)^2\). Observe that

\[(k + 1)! = k!(k + 1) > k^2(k + 1) = k^2 + k^2 = k^2 + k^2 = \frac{k^2}{3} + 16k = k^2 + 2k + 14k > k^2 + 2k + 1 = (k + 1)^2.
\]

By the Principle of Mathematical Induction, \(n! > n^2\) for every integer \(n \geq 4\). 

**7.37 Solution** The following result is being proved.

**Result** Let \(x, y \in \mathbb{Z}\). Then \(3x + 5y\) is odd if and only if \(7x - 11y\) is odd.

For both implications, a direct proof is used.

**7.39 Proof** Let \(p(x) = x^3 - 3x + 1\). Then \(p(x)\) is a continuous function on \(\mathbb{R}\). Since \(p(-2) = -1, p(0) = 1, p(1) = 1\) and \(p(2) = 3\), it follows by the Intermediate Value Theorem that there exist real numbers \(a \in (-2, 0), b \in (0, 1)\) and \(c \in (1, 2)\) such that \(p(a) = p(b) = p(c) = 0\). 

**7.41** Since the proposed formula \(\frac{\sum_{i=1}^{n} i^3}{n^2}\) for \(\sum_{i=1}^{n} i\) is incorrect, the proposed proof must be incorrect and it is. The second sentence of the proposed proof (First, observe that the statement is true for \(n = 1\)) is incorrect. Clearly, \(\sum_{i=1}^{1} i = 1\), while \(\frac{\sum_{i=1}^{n} i^3}{n^2} = \frac{n^2}{n} = k^2\) when \(n = 1\). The proof of the inductive step is correct, however. This illustrates the importance of the basis step of an induction proof.

Since the statement is false, the proposed proof is incorrect. In the proposed proof, it is assumed for a nonnegative integer \(k\) that \(e^i = 1\) for every integer \(i \) with \(0 \leq i \leq k\). We are asked to observe that

\[e^{i+1} = \frac{e^{i} \cdot e} {e^{i-1}} = \frac{1 \cdot 1} {1} = 1.
\]

Clearly, \(e^{k+1} = e^{k\cdot e}\). However, when \(k = 0\), this states that \(e^i = \frac{\phi}{e}\). While \(e^0 = 1\), it is not the case that \(e^{-1} = 1\). This was never assumed. Hence, we have no value for \(e^{k+1}\) when \(k = 0\). What is written is incorrect.

**7.45 Solution** The following result is being proved.

**Result** For every nonnegative integer \(n\), \(3^n + 1 \geq (n + 1)^2\).

A proof by induction is being used. However, it would have been good to begin the proof by saying that induction is being used and to end the proof by stating that it follows that \(3^n + 1 \geq (n + 1)^2\) for every nonnegative integer \(n\) by the Principle of Mathematical Induction.

[Note: The necessity of treating \(k = 0\) separately in the inductive step is important here.]

**7.47** The proposed proof is difficult to follow. The proof below is better. First, we could refer to the result in Exercise 4.90 as a lemma.

**Lemma** Let \(a, b, c, d \in \mathbb{R}\). If \(a \geq b \geq 0\) and \(c \geq d \geq 0\), then \(ac \geq bd\).

**Proof** Since \(n \geq 10\), it follows that \(n^2 \geq 100\) and \(n - 9 \geq 1\). By the lemma, \(n^2(n - 9) \geq 100\) and so \(n^3 - 9n^2 \geq 100\). Hence, \(n^3 \geq 100 + 9n^2\).
Answers to Odd-Numbered Section Exercises

7.49 Proof We proceed by induction. Since \( a_1 = 1 = \frac{1}{1} \), the formula holds for \( n = 1 \). Assume that \( a_k = \frac{1}{k} \) for a positive integer \( k \). Since

\[
a_{k+1} = \frac{k}{k+1} a_k = \left( \frac{k}{k+1} \right) \left( \frac{1}{k} \right) = \frac{1}{k+1},
\]

the formula holds for \( k + 1 \). By the Principle of Mathematical Induction, \( a_n = \frac{1}{n} \) for every positive integer \( n \). ■

EXERCISES FOR CHAPTER 8

Section 8.1: Conjectures in Mathematics

8.1 (a) \( 17 + 18 + \cdots + 25 = 64 + 125 \).
(b) Conjecture For every nonnegative integer \( n \),

\[
(n^2 + 1) + (n^2 + 2) + \cdots + (n + 1)^2 = n^3 + (n + 1)^3.
\]
We use induction. Since \( 1 = 0^3 + 1^3 \), the statement is true for \( n = 0 \). Assume that

\[
(k^2 + 1) + (k^2 + 2) + \cdots + (k + 1)^2 = k^3 + (k + 1)^3
\]
for some nonnegative integer \( k \). We show that

\[
[(k + 1)^2 + 1] + [(k + 1)^2 + 2] + \cdots + [(k + 1) + 1]^2 = (k + 1)^3 + (k + 2)^3
\]
With the aid of Result 6.4, which states that \( 1 + 2 + \cdots + n = n(n + 1)/2 \) for each positive integer \( n \), we obtain

\[
[(k + 1)^2 + 1] + [(k + 1)^2 + 2] + \cdots + [(k + 1) + 1]^2
= (2k + 3)(k + 1)^2 + [1 + 2 + \cdots + (2k + 3)]
= (2k + 3)(k + 1)^2 + (k + 2)(2k + 3)
= (k + 1)(k + 1)^2 + (k + 2)(k + 1)^2 + (k + 2)(2k + 3)
= (k + 1)^3 + (k + 2)(k^2 + 4k + 4) = (k + 1)^3 + (k + 2)^3.
\]
By the Principle of Mathematical Induction,

\[
(n^2 + 1) + (n^2 + 2) + \cdots + (n + 1)^2 = n^3 + (n + 1)^3
\]
for every nonnegative integer \( n \). ■

8.3 (a) \( a_2 = 3, a_3 = 8, a_4 = 54 \).
(b) For each \( n \in \mathbb{N} \), \( a_n \) is an integer.
8.5 (a) The ordered partitions of 4 are 4, 3 + 1, 1 + 3, 2 + 2, 2 + 1 + 1, 1 + 2 + 1, 1 + 1 + 1 + 1. So, there are 8 ordered partitions of 4.
(b) Conjecture For each positive integer \( n \), there are \( 2^{n-1} \) ordered partitions of \( n \). [This conjecture is true.]
8.7 (a) \( 4 \cdot 2 \cdot 1 \cdot 1 = 4 + 2 + 1 + 1 \).
(b) \( 3 \cdot 3 \cdot 1 \cdot 1 \cdot 1 = 3 + 3 + 1 + 1 + 1 \).
(c) Conjecture For every integer \( n \geq 3 \), there exist \( n \) positive integers whose sum equals their product. [This conjecture is true.]
8.9 (a) \( a_3 = 1 + \frac{1}{7} + \frac{1}{3} = \frac{11}{7}; a_4 = 1 + \frac{1}{7} + \frac{1}{3} + \frac{1}{4} = \frac{25}{14} \).
(b) Conjecture For each integer \( n \geq 2 \), \( a_n \) is not an integer. [The conjecture is true.]

Section 8.2: Revisiting Quantified Statements

8.11 (a) Let \( S \) be the set of all positive even integers and let \( P(n) : 3n + 2^{n-2} \) is odd.
\[ \exists n \in S, P(n). \]
(b) Proof For \( n = 2 \in S \), \( 3n + 2^{n-2} = 7 \) is odd. ■
8.13 (a) Let \( P(n) : 3n^2 - 5n + 1 \) is an even integer.
\[ \forall n \in \mathbb{Z}, P(n). \]
(b) We show the following: For all \( n \in \mathbb{Z} \), \( 3n^2 - 5n + 1 \) is odd.
This can be proved by a direct proof with two cases, namely \( n \) even and \( n \) odd.

8.15 (a) Let \( P(m, n) : m(n - 3) < 1. \)
\[ \exists n \in \mathbb{Z}, \forall m \in \mathbb{Z}, P(m, n). \]
(b) \textbf{Proof} \ Let \( n = 3 \). Then \( m(n - 3) = m \cdot 0 = 0 \not< 1. \)

8.17 (a) Let \( P(m, n) : -nm < 0. \exists n \in \mathbb{N}, \forall m \in \mathbb{Z}, P(m, n). \)
(b) \( \forall n \in \mathbb{N}, \exists m \in \mathbb{Z}, \sim P(m, n). \)
(c) Let \( n \) be a positive integer. For \( m = 0 \), we have \( -nm = -n \cdot 0 = 0. \)

8.19 (a) Let \( P(a, b, x) : a \leq x \leq b \) and \( b - a = 1. \)
\[ \forall x \in \mathbb{R}, \exists a, b \in \mathbb{Z}, P(a, b, x). \]
(b) \textbf{Proof} \ Let \( x \in \mathbb{R} \). If \( x \) is an integer, then let \( a = x \) and \( b = x + 1 \). Then \( a \leq x \leq b \) and \( b - a = 1 \). Thus, we may assume that \( x \) is not an integer. Then there exists an integer \( a \) such that \( a < x < a + 1 \). Let \( b = a + 1 \).

8.21 (a) Let \( S \) be the set of even integers, let \( T \) be the set of odd integers and let \( P(a, b, c) : a < c < b \) or \( b < c < a \).
\[ \forall a \in S, \forall b \in T, \exists c \in Q, P(a, b, c). \]
(b) \textbf{Proof} \ For \( a \in S \) and \( b \in T \), let \( c = (a + b)/2 \). If \( a < b \), then \( a < c < b \); while if \( b < a \), then \( b < c < a \).

8.23 (a) Let \( S \) be the set of odd integers and \( P(a, b, c) : a + b + c = 1 \).
\[ \exists a, b, c \in S, P(a, b, c). \]
(b) \textbf{Proof} \ Let \( a = 3 \) and \( b = c = -1 \). Then \( a + b + c = 1 \).

8.25 (a) \( \exists L \in \mathbb{R}, \forall e \in \mathbb{R}^+, \exists d \in \mathbb{R}^+, \forall x \in \mathbb{R}, P(x, d) \Rightarrow Q(x, L, e). \)
(b) \textbf{Proof} \ Let \( L = 0 \) and let \( e \) be any positive real number. Let \( d = e/3 \). Let \( x \in \mathbb{R} \) such that \( |x| < e/3 \). Then \( |3x - L| = |3x| = 3|x| < 3(e/3) = e \).

8.27 \textbf{Proof} \ Let \( a \in \mathbb{Z} \). Then \( b = a - 1 \) and \( c = 0 \) are integers such that \( |a - b| = 1 > cd = 0 \cdot d = 0 \) for every integer \( d \).

Section 8.3: Testing Statements

8.29 (a) The statement is true. \textbf{Proof} \ Assume that \( k^2 + 3k + 1 \) is even where \( k \in \mathbb{N} \). Then \( k^2 + 3k + 1 = 2x \) for some integer \( x \). Observe that
\[
(k + 1)^2 + 3(k + 1) + 1 = k^2 + 2k + 1 + 3k + 3 + 1 = (k^2 + 3k + 1) + 2k + 4 = 2x + 2k + 4 = 2(x + k + 2).
\]
Since \( x + k + 2 \) is an integer, \( (k + 1)^2 + 3(k + 1) + 1 \) is even. 
(b) The statement is false since \( P(1) \) is false.

8.31 This statement is false. Let \( n = 0 \) and let \( k \) be any nonnegative integer. Since \( k \geq 0 = n \), the integer \( n = 0 \) is a counterexample.

8.33 This statement is false. Let \( x = 99 \) and \( y = z = 1 \). Then \( x + y + z = 101 \), while no two of \( x, y \) and \( z \) are of opposite parity. Thus, \( x = 99, y = 1, z = 1 \) is a counterexample.

8.35 The statement is true. \textbf{Proof} \ Assume that \( A \neq \emptyset \). Since \( A \neq \emptyset \), there is an element \( a \in A \). Let \( B = \{a\} \). Then \( A \cap B \neq \emptyset \).

8.37 The statement is false. Let \( A = \{1\} \), which is nonempty, and let \( B \) be an arbitrary set. Since \( 1 \in A \cup B \), it follows that \( A \cup B \neq \emptyset \).

8.39 The statement is true. \textbf{Proof} \ Let \( A \) be a proper subset of \( S \) and let \( B = S - A \). Then \( B \neq \emptyset \), \( A \cup B = S \) and \( A \cap B = \emptyset \).

8.41 The statement is true. Observe that \( 0 \cdot c = 0 \) for every integer \( c \).

8.43 The statement is false. Let \( x = 1 \) and \( y = -2 \). Then \( x^2 < y^2 \) but \( x > y \).

8.45 The statement is true. \textbf{Proof} \ Let \( a \) be an odd integer. Then \( a = a + 1 + (-1) \) is a sum of three odd integers.

8.47 The statement is true. Let \( b = c - a \).
The statement is true. Consider \( r = (a + b)/2. \)

The statement is false. Let \( A \neq \emptyset \) and \( B = \emptyset. \) Then \( A \cup B \neq \emptyset. \)

The statement is true. \( R_1 = \mathbb{N} \backslash \mathbb{Q} \) is transitive but neither reflexive nor symmetric.

The statement is true. Let \( f(x) = x^3 + x^2 - 1. \) Observe that \( f(0) = -1 \) and \( f(1) = 1. \) Now apply the Intermediate Value Theorem of Calculus.

The statement is false. Assume that \( A - B \neq \emptyset. \) Then there exists \( x \in A - B. \) Thus, \( x \in A \) and \( x \notin B. \) Since \( x \notin B, \) it follows that \( x \notin B - A. \) Therefore, \( A - B \neq B - A. \)

The statement is true. \( R \) is transitive but neither reflexive nor symmetric.

The statement is false. For \( A = \emptyset, B = \{1\} \) and \( C = \{1, 2\}, \) we have \( A \cap B = A \cap C = \emptyset, \) but \( B \neq C. \) Thus, \( A, B \) and \( C \) form a counterexample.

The statement is true. \( A \subseteq \mathbb{N} = \{1, 2, 3\}. \) Then the statement would be true.

The statement is true. For a nonzero rational number \( A = \frac{1}{2}, B = \frac{1}{3}, C = \frac{1}{4}, \) \( A \) and \( B \) have the same number 4 of elements, there is an element \( x \in A - B \) and an element \( y \in B - A. \) Since \( R = R^{-1} \), it follows that \( x \) is related to \( y \) but not to \( y \) related to \( x. \) This implies that \( R \subseteq (A - \{x\}) \times (B - \{y\}). \) Since \( |A - \{x\}| \times |B - \{y\}| = 3 \cdot 3 = 9, \) this is a contradiction.

The statement is true. Consider \( \mathbb{Z} \) as a relation from \( \mathbb{N} \) to \( \mathbb{N} \).

The statement is true. \( \mathbb{Z} \) is reflexive and transitive. Since \( (a, d) \in R \) and \( (d, a) \notin R, \) it follows that \( R \) is not symmetric.

The statement is true. \( \mathbb{Z} \) is transitive but neither reflexive nor symmetric.

The statement is true. \( \mathbb{Z} \) is reflexive and symmetric. Observe that \( 3 R 1 \) and \( 1 R 0 \) but \( 3 \notin R \). Thus, \( R \) is not transitive.

The statement is true. \( \mathbb{Z} \) is symmetric and transitive but not reflexive.

### Exercises for Chapter 9

#### Section 9.1: Relations

**9.1** \( \text{dom}(R) = \{a, b\} \) and \( \text{range}(R) = \{s, t\}. \)

**9.3** Since \( A \times A = \{(0, 0), (0, 1), (1, 0), (1, 1)\} \) and \( |A \times A| = 4, \) the number of subsets of \( A \times A \) is \( 2^4 = 16. \)

Hence, the number of relations on \( A \) is also 16. Four of these 16 relations are \( \emptyset, A \times A, \{(0, 0)\} \) and \( \{(0, 0), (0, 1), (1, 0)\}. \)

**9.5** \( R^{-1} = \{(1, 1), (2, 1), (2, 2), (3, 1), (3, 2), (3, 3)\}. \)

**9.7** For \( a, b \in \mathbb{N}, a R^{-1} b \) if and only if \( b R a \). Therefore, \( a = b \) is odd.

**9.9 (a)** The statement is false. Let \( A = \{1, 2, 3, 4\}, B = \{1, 2, 3, 5\} \) and \( C = \{2, 3, 4\}. \) Then \( |A| = |\emptyset| = 4. \) Then \( R = C \times C \) is a relation from \( A \) to \( B \) with \( |R| = 9 \) and \( R = R^{-1} \) but \( A \neq B. \) Thus, \( A, B \) and \( C \) constitute a counterexample.

**9.11** The relation \( R \) is reflexive and transitive. Since \( (a, d) \in R \) and \( (d, a) \notin R, \) it follows that \( R \) is not symmetric.

**9.13** The relation \( R \) is transitive but neither reflexive nor symmetric.

**9.15** The relation \( R \) is reflexive and symmetric. Observe that \( 3 R 1 \) and \( 1 R 0 \) but \( 3 \notin R \). Thus, \( R \) is not transitive.

**9.17** The relation \( R \) is symmetric and transitive but not reflexive.
Since $b \in \mathbb{Z}$, it follows that $a R b$ is symmetric, $a R a$ is an integer with $0 \leq b \leq 3$, and $a R b$ is transitive. Assume that $a R a$ is transitive. Since $a R a$ is transitive, we have $a R b$ and $b R c$ but $a R c$.

9.19 The relation $R$ is reflexive and symmetric. Observe that $-1 R 0$ and $0 R 2$ but $-1 \neq 2$. Thus, $R$ is not transitive.

9.21 The statement is true. Proof Let $A = \{a_1, a_2\}$ and suppose that $R$ is a relation on $A$ that has none of the properties reflexive, symmetric and transitive. Since $R$ is not symmetric, we may assume that $a_1, R a_2$ but $a_2 R a_1$. Since at most one of $(a_1, a_1)$ and $(a_2, a_2)$ belongs to $R$, it follows that $R$ is transitive, which is a contradiction.

Section 9.3: Equivalence Relations

9.25 There are three distinct equivalence classes, namely $[1] = \{1, 5\}, [2] = \{2, 3, 6\}$ and $[4] = \{4\}.$

9.27 Proof Since $a^3 = a^3$ for each $a \in \mathbb{Z}$, it follows that $a R a$ and $R$ is reflexive. Let $a, b \in \mathbb{Z}$ such that $a R b$. Then $a^3 = b^3$ and so $b^3 = a^3$. Thus, $b R a$ and $R$ is symmetric. Let $a, b, c \in \mathbb{Z}$ such that $a R b$ and $b R c$. Thus, $a^3 = b^3$ and $b^3 = c^3$. Hence, $a^3 = c^3$ and so $a R c$ and $R$ is transitive.

9.29 Proof Assume that $a R b$, $c R d$ and $a R d$. Since $a R b$ and $R$ is symmetric, $b R a.$ Similarly, $d R c$. Because $b R a$, $a R d$ and $R$ is transitive, $b R d$. Finally, since $b R d$ and $d R c$, it follows that $b R c$, as desired.

9.31 Proof First assume that $R$ is an equivalence relation on $A$. Thus, $R$ is reflexive. It remains only to show that $R$ is circular. Assume that $x R y$ and $y R z$. Since $R$ is transitive, $x R z$. Since $R$ is symmetric, $z R x$. Thus, $R$ is circular.

For the converse, assume that $R$ is a reflexive, circular relation on $A$. Since $R$ is reflexive, it remains only to show that $R$ is symmetric and transitive. Let $x, y \in A$ such that $x R y$. Since $R$ is reflexive, $y R y$. Because (1) $x R y$ and $y R y$ and (2) $y R y$ is circular, it follows that $y R x$ and so $R$ is symmetric. Let $x, y, z \in A$ such that $x R y$ and $y R z$. Since $R$ is circular, $z R x$. Now because $R$ is symmetric, we have $x R z$. Thus, $R$ is transitive.

Therefore, $R$ is an equivalence relation on $A$.

9.33 (a) Proof Let $a \in \mathbb{Z}$. Since $a - a = 4 \cdot 0 \in H$, it follows that $a R a$ and $R$ is reflexive. Next, assume that $a R b$, where $a, b \in \mathbb{Z}$. Then $a - b \in H$ and so $a = 4k$, where $k \in \mathbb{Z}$. Then $b - a = 4(-k)$. Since $-k \in \mathbb{Z}$, it follows that $b - a \in H$ and $b R a$. Therefore, $R$ is symmetric. Finally, assume that $a R b$ and $b R c$ where $a, b, c \in \mathbb{Z}$. Then $a - b \in H$ and $b - c \in H$. So, $a - b = 4k$ and $b - c = 4\ell$ for $k, \ell \in \mathbb{Z}$. Therefore, $a - c = (a - b) + (b - c) = 4k + 4\ell = 4(k + \ell)$. Since $k + \ell \in \mathbb{Z}$, it follows that $a - c \in H$ and so $a R c$. Thus, $R$ is transitive and $R$ is an equivalence relation.

(b) Let $a \in \mathbb{Z}$. Then
\[
[a] = \{x \in \mathbb{Z} : x R a\} = \{x \in \mathbb{Z} : x - a = 4k\} = \{a + 4k : k \in \mathbb{Z}\}.
\]

Since every integer can be expressed as $4k + r$ where $r$ is an integer with $0 \leq r \leq 3$, it follows that the distinct equivalence classes are $[0], [1], [2]$ and $[3]$, where $[r] = \{4k + r : k \in \mathbb{Z}\}$ for $r = 0, 1, 2, 3$.

9.35 The statement is false. Suppose that there are equivalence relations $R_1$ and $R_2$ on $S = \{a, b, c\}$ such that $R_1 \cap R_2 = \emptyset$ and $R_1 \cup R_2 = S \times S$. Since $R_1$ and $R_2$ are both reflexive, it follows that $(a, a), (b, b), (c, c) \in R_1 \cap R_2$. Because $R_1 \cap R_2$, there exists some element of $R_1$ that is not in $R_2$, say $(a, b) \in R_1 - R_2$. Necessarily then, $(b, a) \in R_1 - R_2$ as well. Because $R_2 \cap R_1$, there exists some element of $R_2$ that is not in $R_1$. We may assume that $(b, b) \in R_2 - R_1$. Thus, $(c, b) \in R_2 - R_1$. Since $R_1 \cup R_2 = S \times S$, it follows that $(a, c) \in R_1 \cup R_2$. We may assume that $(a, c) \in R_1$. Since $(b, a) \in R_1$, it follows by the transitive property that $(b, c) \in R_1$, which is not true.

Section 9.4: Properties of Equivalence Classes

9.37 Let $a \in \mathbb{N}$. Then $a^2 + a^2 = 2(a^2)$ is an even integer and so $a R a$. Thus, $R$ is reflexive. Assume that $a R b$, where $a, b \in \mathbb{N}$. Then $a^2 + b^2$ is even. Since $b^2 + a^2 = a^2 + b^2$, it follows that $b^2 + a^2$ is even. Therefore, $b R a$ and $R$ is symmetric. Finally, show that $R$ is transitive.
There are two distinct equivalence classes:

$[1] = \{ x \in \mathbb{N} : x^2 + 1 \text{ is even} \} = \{ x \in \mathbb{N} : x^2 \text{ is odd} \} = \{ x \in \mathbb{N} : x \text{ is odd} \}$

$[2] = \{ x \in \mathbb{N} : x^2 + 4 \text{ is even} \} = \{ x \in \mathbb{N} : x^2 \text{ is even} \} = \{ x \in \mathbb{N} : x \text{ is even} \}$

9.39 (a) **Proof** First, we show that $R$ is reflexive. Let $x \in S$. Then $x + 2x = 3x$. Since $3 \mid (x + 2x)$, it follows that $x R x$ and $R$ is reflexive. Next, we show that $R$ is symmetric. Let $x R y$, where $x, y \in S$. Then $3 \mid (x + 2y)$ and so $x + 2y = 3a$, where $a \in \mathbb{Z}$ and so $x = 3a - 2y$. Thus, $y + 2x = y + 2(3a - 2y) = 6a - 3y = 3(2a - y)$. Since $2a - y$ is an integer, $3 \mid (y + 2x)$. Thus, $y R x$ and $R$ is symmetric.

Finally, we show that $R$ is transitive. Let $x R y$ and $y R z$, where $x, y, z \in S$. Then $3 \mid (x + 2y)$ and $3 \mid (y + 2z)$. So, $x + 2y = 3a$ and $y + 2z = 3b$, where $a, b \in \mathbb{Z}$. Thus, $(x + 2y) + (y + 2z) = 3a + 3b$ and so $x + 2z = 3(a + b - y)$. Since $a + b - y$ is an integer, $3 \mid (x + 2z)$ and so $x R z$. Therefore, $R$ is transitive.

(b) There are three distinct equivalence classes:

$[0] = \{ 0, -6 \}$, $[1] = \{ 1, -2, 4, 7 \}$ and $[-7] = \{-7, 5\}$.

9.41 (a) Suppose that $R_1$ and $R_2$ are two equivalence relations defined on a set $S$. Let $R = R_1 \cap R_2$. First, we show that $R$ is reflexive. Let $a \in S$. Since $R_1$ and $R_2$ are equivalence relations on $S$, it follows that $(a, a) \in R_1$ and $(a, a) \in R_2$. Thus, $(a, a) \in R$ and so $R$ is reflexive. Assume that $a R b$, where $a, b \in S$. Then $(a, b) \in R_1$ and $(b, a) \in R_2$. Since $R_1$ and $R_2$ are symmetric, $(b, a) \in R_1$ and $(a, b) \in R_2$. Thus, $(b, a) \in R$ and so $b R a$. Hence, $R$ is symmetric. Finally, show that $R$ is transitive.

(b) Let $a \in \mathbb{Z}$. For $x \in \mathbb{Z}$, it follows that $x R_1 a$ if and only if $x R_2 a$ and $x R_3 a$. That is, $x R_1 a$ if and only if $x \equiv a \pmod{2}$ and $x \equiv a \pmod{3}$. First, suppose that $x \equiv a \pmod{2}$ and $x \equiv a \pmod{3}$. Hence, $x = a + 2k$ and $x = a + 3\ell$ for some integers $k$ and $\ell$. Therefore, $2k = 3\ell$ and so $\ell$ is even. Then, $\ell = 2m$ for some integer $m$, implying that $x = a + 3\ell = a + 3(2m) = a + 6m$ and so $x - a = 6m$. Hence, $x \equiv a \pmod{6}$. If $x \equiv a \pmod{6}$, then $x \equiv a \pmod{2}$ and $x \equiv a \pmod{3}$. Thus,

$[a] = \{ x \in \mathbb{Z} : x \equiv a \pmod{6} \}$.

$[0] = \{ \ldots, -12, -6, 0, 6, 12, \ldots \}$, $[1] = \{ \ldots, -11, -5, 1, 7, 13, \ldots \}$,

$[2] = \{ \ldots, -10, -4, 2, 8, 14, \ldots \}$, $[3] = \{ \ldots, -9, -3, 3, 9, 15, \ldots \}$,

$[4] = \{ \ldots, -8, -2, 4, 10, 16, \ldots \}$, $[5] = \{ \ldots, -7, -1, 5, 11, 17, \ldots \}$.

9.43 **Proof** For $a_i \in A, [a_i] = \{ x \in A : x R a_i \} = \{ x \in A : (x, a_i) \in R \}$. Therefore, $|[a_i]|$ counts all those ordered pairs in $R$ for which $a_i$ is the second coordinate and so $\sum_{i=1}^{n} |[a_i]|$ counts all ordered pairs in $R$, that is, $\sum_{i=1}^{n} |[a_i]| = |R|$. Since $R$ is reflexive, $(a_i, a_i) \in R$ for $i = 1, 2, \ldots, n$ and for each pair $i, j$ of distinct integers, either $(a_i, a_j)$ and $(a_j, a_i)$ both belong to $R$ or neither belongs to $R$. Suppose that there are $k$ ordered pairs $(a_i, a_j)$ in $R$ with $1 \leq i < j \leq n$. Then $|R| = n + 2k$ and so $\sum_{i=1}^{n} |[a_i]|$ is even if and only if $n$ is even.

Section 9.5: Congruence Modulo $n$

9.45 Let $a \in \mathbb{Z}$. Since $3a + 5a = 8a$, it follows that $8 \mid (3a + 5a)$ and so $3a + 5a \equiv 0 \pmod{8}$. Hence, $a R a$ and $R$ is reflexive. Next, we show that $R$ is symmetric. Assume that $a R b$, where $a, b \in \mathbb{Z}$. Then $3a + 5b \equiv 0 \pmod{8}$, that is, $3a + 5b = 8k$ for some integer $k$. Observe that $(3a + 5b) + (3b + 5a) = 8a + 8b$. Thus,

$3b + 5a = 8a + 8b - (3a + 5b) = 8a + 8b - 8k = 8(a + b - k)$.

Since $a + b - k$ is an integer, $8 \mid (3b + 5a)$ and so $3b + 5a \equiv 0 \pmod{8}$. Hence, $b R a$ and $R$ is symmetric. Finally, show that $R$ is transitive.

9.47 There are two distinct equivalence classes, namely,

$[0] = \{ 0, \pm 2, \pm 4, \ldots \}$ and $[1] = \{ \pm 1, \pm 3, \pm 5, \ldots \}$.

9.49 **Proof** Let $a \in \mathbb{Z}$. Since $5a - 2a = 3a$, it follows that $3 \mid (5a - 2a)$ and so $5a \equiv 2a \pmod{3}$. Hence, $a R a$ and $R$ is reflexive.

Next, we show that $R$ is symmetric. Assume that $a R b$, where $a, b \in \mathbb{Z}$. Then $5a \equiv 2b \pmod{3}$, that is, $5a - 2b = 3k$ for some integer $k$. Observe that $(5a - 2b) + (5b - 2a) = 3a + 3b$. Thus,

$5b - 2a = 3a + 3b - (5a - 2b) = 3a + 3b - 3k = 3(a + b - k)$.

Since $a + b - k$ is an integer, $3 \mid (5b - 2a)$ and so $5b \equiv 2a \pmod{3}$. Hence, $b R a$ and $R$ is symmetric.
Finally, we show that $R$ is transitive. Assume that $a R b$ and $b R c$, where $a, b, c ∈ ℤ$. Thus, $5a ≡ 2b (\text{mod } 3)$ and $5b ≡ 2c (\text{mod } 3)$. So, $5a - 2b = 3x$ and $5b - 2c = 3y$, where $x, y ∈ ℤ$. Observe that

$$(5a - 2b) + (5b - 2c) = (5a - 2c) + 3b = 3x + 3y.$$  

Thus, $5a - 2c = 3x + 3y - 3b = 3(x + y - b)$. Since $x + y - b$ is an integer, $3 | (5a - 2c)$ and $5a ≡ 2c (\text{mod } 3)$. Therefore, $a R c$ and $R$ is transitive.

9.51 First, we show that $R$ is reflexive. Let $a ∈ ℤ$. Since $2a + 3a = 5a$, it follows that $5 | (2a + 3a)$ and so $a R a$. Hence, $R$ is reflexive. Next, we show that $R$ is symmetric. Assume that $a R b$, where $a, b ∈ ℤ$. Then $2a + 3b ≡ 0 (\text{mod } 5)$. Hence, $2a + 3b = 5k$ for some integer $k$. Observe that $(2a + 3b) + (2b + 3a) = 5a + 5b$. Thus,

$$2b + 3a = 5a + 5b - (2a + 3b) = 5a + 5b - 5k = 5(a + b - k).$$  

Since $a + b - k$ is an integer, $5 | (2b + 3a)$ and so $2b + 3a ≡ 0 (\text{mod } 5)$. Hence, $b R a$ and $R$ is symmetric. Finally, show that $R$ is transitive.

The distinct equivalence classes are $[0], [1], [2], [3]$ and $[4]$, where, for $0 ≤ r ≤ 4$, $[r] = \{5q + r : q ∈ ℤ\}$.

9.53 The relation $R$ is an equivalence relation. Proof Let $a ∈ ℤ$. Since $a - a = 0 = 0 · π$, it follows that $a R a$ and $R$ is reflexive. Next, suppose that $a R b$, where $a, b ∈ ℤ$. Then $a - b = kπ$ for some $k ∈ ℤ$. Since $b - a = (-k)π$ and $-k ∈ ℤ$, it follows that $b R a$ and so $R$ is symmetric. Finally, suppose that $a R b$ and $b R c$, where $a, b, c ∈ ℤ$. Then $a - b = kπ$ and $b - c = ℓπ$ for $k, ℓ ∈ ℤ$. Thus, $a - c = (a - b) + (b - c) = (k + ℓ)π$. Because $k + ℓ ∈ ℤ$, $a R c$ and $R$ is transitive. Therefore, $R$ is an equivalence relation.

9.57 (a) Proof Let $a, b ∈ ℤ$. Then $a = 4k$ and $b = 4ℓ$ for $k, ℓ ∈ ℤ$. Thus, $a + b = 4(k + ℓ)$ and $ab = 4(4kℓ)$.

Since $k + ℓ ∈ ℤ$, $4kℓ ∈ ℤ$, it follows that $T$ is closed under addition and multiplication. (b) Yes. Let $a ∈ S - T$ and $b ∈ ℤ$. Then $b = 4ℓ$ for $ℓ ∈ ℤ$. Thus, $ab = 4(aℓ)$. Since $aℓ ∈ ℤ$, it follows that $ab ∈ T$.

9.59 (a) No. Consider $[a] = [2]$ and $[b] = [4]$. Then $[a] ≠ [0]$ and $[b] ≠ [0]$, but $[a] · [b] = [8] = [0]$. (b) If $Z_q$ is replaced by $Z_q$ or $Z_{10}$, then the answer is no; while if $Z_q$ is replaced by $Z_{11}$, then the answer is yes.

9.61 (a) Suppose that an element $[a] ∈ ℤ_n$ also belongs to $ℤ_m$. That is, $[a]$ in $ℤ_m$ is the same set as $[b]$ in $ℤ_n$. Since $a, a + m ∈ [a] ∈ ℤ_m$, it follows that $a, a + m ∈ [b] ∈ ℤ_n$. Therefore, $n | [(a + m) - a)$ or $n | m$. Similarly, $m | n$ and so $n = m$, that is, $ℤ_n = ℤ_m$.

(b) If $m, n ≥ 2$ and $m ⊈ n$, then $ℤ_m ∩ ℤ_n = \emptyset$. For example, $ℤ_2 ∩ ℤ_3 = \emptyset$.

EXERCISES FOR CHAPTER 10

Section 10.1: The Definition of Function

10.1 dom($f$) = $\{a, b, c, d\}$ and range($f$) = $\{y, z\}$.

10.3 Since $R$ is an equivalence relation, $R$ is reflexive. So, $(a, a) ∈ R$ for every $a ∈ A$. Since $R$ is also a function from $A$ to $A$, we must have $R = \{(a, a) : a ∈ A\}$ and so $R$ is the identity function on $A$. 

---

Section 9.6: The Integers Modulo $n$

9.57 (a) Proof Let $a, b ∈ ℤ$. Then $a = 4k$ and $b = 4ℓ$ for $k, ℓ ∈ ℤ$. Thus, $a + b = 4(k + ℓ)$ and $ab = 4(4kℓ)$.

Since $k + ℓ ∈ ℤ$, $4kℓ ∈ ℤ$, it follows that $T$ is closed under addition and multiplication. (b) Yes. Let $a ∈ S - T$ and $b ∈ ℤ$. Then $b = 4ℓ$ for $ℓ ∈ ℤ$. Thus, $ab = 4(aℓ)$. Since $aℓ ∈ ℤ$, it follows that $ab ∈ T$.

9.59 (a) No. Consider $[a] = [2]$ and $[b] = [4]$. Then $[a] ≠ [0]$ and $[b] ≠ [0]$, but $[a] · [b] = [8] = [0]$. (b) If $Z_q$ is replaced by $Z_q$ or $Z_{10}$, then the answer is no; while if $Z_q$ is replaced by $Z_{11}$, then the answer is yes.

9.61 (a) Suppose that an element $[a] ∈ ℤ_n$ also belongs to $ℤ_m$. That is, $[a]$ in $ℤ_m$ is the same set as $[b]$ in $ℤ_n$. Since $a, a + m ∈ [a] ∈ ℤ_m$, it follows that $a, a + m ∈ [b] ∈ ℤ_n$. Therefore, $n | [(a + m) - a)$ or $n | m$. Similarly, $m | n$ and so $n = m$, that is, $ℤ_n = ℤ_m$.

(b) If $m, n ≥ 2$ and $m ⊈ n$, then $ℤ_m ∩ ℤ_n = \emptyset$. For example, $ℤ_2 ∩ ℤ_3 = \emptyset$.

460 Answers to Odd-Numbered Section Exercises

10.5 Let \( A' = \{a \in A : (a, b) \in R \text{ for some } b \in B \} \). Furthermore, for each element \( a' \in A' \), select exactly one element \( b' \in \{b \in B : (a', b) \in R \} \). Then \( f = \{(a', b') : a' \in A'\} \) is a function from \( A' \) to \( B \).

10.7 \( R = \{(3, 4), (17, 6), (29, 60), (45, 22)\} \) and so \( R \) is a function from \( A \) to \( B \).

10.9 (a) Since \( 0 R_1 \) and \( 0 R_1 \), \( R_1 \) is not a function.

(b) Since \( 0 R_1 (\frac{3}{2}) \) and \( 0 R_1 (\frac{3}{2}) \), \( R_2 \) is not a function.

(c) For each \( a \in N, b = (1 - 3a)/5 \in Q \) is the unique element such that \( 3a + 5b = 1 \). So, \( R_3 \) defines a function.

(d) For each \( x \in R, y = 4 - |x - 2| \) is a unique element of \( R \). So, \( R_4 \) defines a function.

(e) Since \( 0 R_1 \) and \( 0 R_1 \), \( R_5 \) is not a function.

10.11 (a) \( f(C) = C, f^{-1}(C) = C \cup \{x \in R : -x \in C\} \), \( f^{-1}(D) = R - \{0\}, f^{-1}((1)) = \{1, -1\} \).

(b) \( f(C) = [0, \infty), f^{-1}(C) = [e, \infty), f^{-1}(D) = (1, \infty), f^{-1}((1)) = \{e\} \).

(c) \( f(C) = [e, \infty), f^{-1}(C) = [0, \infty), f^{-1}(D) = R, f^{-1}((1)) = \{0\} \).

(d) \( f(C) = [-1, 1], f^{-1}(C) = (\frac{\pi}{2} + 2n\pi : n \in Z) \), \( f^{-1}(D) = \cup_{n\in \mathbb{Z}}(2n\pi, (2n+1)\pi) \).

(e) \( f(C) = (-\infty, 1], f^{-1}(C) = \{1\}, f^{-1}(D) = (0, 2), f^{-1}((1)) = \{1\} \).

10.13 \( B^4 = \{f_1, f_2, \ldots, f_8\} \), where \( f_2 = \{(1, x), (2, x), (3, x)\} \), \( f_1 = \{(1, x), (2, x), (3, y)\} \), \( f_5 = \{(1, x), (2, y), (3, x)\} \), \( f_4 = \{(1, x), (2, y), (3, y)\} \). By interchanging \( x \) and \( y \) in \( f_1, f_2, f_3, f_4 \), we obtain \( f_5, f_6, f_7, f_8 \).

10.15 For \( A = \{a, b, c\} \) and \( B = \{0, 1\} \), there are 8 different functions from \( A \) to \( B \), namely \( f_1 = \{(a, 0), (b, 0), (c, 0)\} \), \( f_5 = \{(a, 0), (b, 0), (c, 1)\} \).

10.17 (a) A reasonable interpretation of \( C^{B^4} \) is \( \{f : f : B^4 \to C\} \).

(b) For \( A = \{0, 1\} \) and \( B = \{a, b\} \), \( B^4 = \{f_1, f_2, f_3, f_4\} \), where \( f_2 = \{(0, a), (1, a)\}, f_1 = \{(0, a), (1, b)\} \), \( f_3 = \{(0, b), (1, a)\} \) and \( f_4 = \{(0, b), (1, b)\} \).

Then for \( C = \{x, y\}, C^{B^4} = \{g_1, g_2, \ldots, g_{16}\} \), where \( g_1 = \{(f_1, x), (f_2, x), (f_3, x), (f_4, x)\} \), \( g_2 = \{(f_1, x), (f_2, y), (f_3, x), (f_4, y)\} \), \( g_3 = \{(f_1, y), (f_2, x), (f_3, y), (f_4, x)\} \).
10.29 \textbf{Proof} \hspace{1em} By Exercise 10.12(b), \( f(C \cap D) \subseteq f(C) \cap f(D) \). So, it remains to show that \( f(C) \cap f(D) \subseteq f(C \cap D) \) under the added hypothesis that \( f \) is one-to-one. Let \( y \in f(C) \cap f(D) \). Then \( y \in f(C) \) and \( y \in f(D) \). Since \( y \in f(C) \), there exists \( x \in C \) such that \( y = f(x) \). Furthermore, since \( y \in f(D) \), there exists \( z \in D \) such that \( y = f(z) \). Since \( f \) is one-to-one, \( z = x \). Thus, \( x \in C \cap D \) and so \( y \in f(C \cap D) \). Therefore, \( f(C) \cap f(D) \subseteq f(C \cap D) \) and so \( f(C \cap D) = f(C) \cap f(D) \).

\section*{Section 10.3: Bijective Functions}

10.31 \hspace{1em} (a) \textbf{Proof} \hspace{1em} Let \( [a], [b] \in \mathbb{Z} \) such that \( [a] = [b] \). We show that \( f([a]) = f([b]) \), that is, \( 2a + 3 = 2b + 3 \). Since \( [a] = [b] \), it follows that \( a \equiv b \pmod{5} \) and so \( a - b = 5x \) for some integer \( x \). Observe that

\[(2a + 3) - (2b + 3) = 2(a - b) = 2(5x) = 5(2x).
\]

Since \( 2x \) is an integer, \( 5 \mid [(2a + 3) - (2b + 3)] \). Therefore, \( 2a + 3 \equiv 2b + 3 \pmod{5} \) and so \( [2a + 3] = [2b + 3] \).

\hspace{1em} (b) \hspace{1em} Since \( f([0]) = [3], f([1]) = [0], f([2]) = [2], f([3]) = [4] \) and \( f([4]) = [1] \), it follows that \( f \) is one-to-one and onto and so \( f \) is bijective.

10.33 \hspace{1em} Define \( f_1(x) = x^2 \) for \( x \in A \) and \( f_2(x) = \sqrt{x} \) for \( x \in A \). (\( f_3(x) = 1 - x \) is another example.)

10.35 \hspace{1em} (a) \hspace{1em} Consider \( S = [2, 5, 6] \). Observe that for each \( y \in B \), there exists \( x \in S \) such that \( x \) is related to \( y \). This says that \( \gamma(R) \leq 3 \). On the other hand, let \( S' \subseteq S \) such that for every element \( y \) of \( B \), there is an element \( x \in S' \) such that \( x \) is related to \( y \). Observe that \( S' \) must contain \( 6 \), at least one of \( 2 \) and \( 3 \) and at least one of \( 4, 5 \) and \( 7 \). Thus, \( |S'| \geq 3 \). Therefore, \( \gamma(R) = 3 \).

\hspace{1em} (b) \hspace{1em} If \( R \) is an equivalence relation defined on a finite nonempty set \( A \), then \( \gamma(R) \) is the number of distinct equivalence classes of \( R \).

\hspace{1em} (c) \hspace{1em} If \( f \) is a bijective function from \( A \) to \( B \), then \( \gamma(f) = |A| \).

\section*{Section 10.4: Composition of Functions}

10.37 \hspace{1em} \( g \circ f = \{(1, y), (2, x), (3, x), (4, x)\} \).

10.39 \hspace{1em} (a) \hspace{1em} \( (g \circ f)([a]) = g(f([a])) = g([3a]) = [21a] = [a] \), \( (f \circ g)([a]) = f(g([a])) = f([7a]) = [21a] = [a] \).

\hspace{1em} (b) \hspace{1em} Each of \( g \circ f \) and \( f \circ g \) is the identity function on \( \mathbb{Z}_{10} \).

10.41 \hspace{1em} \textbf{Proof} \hspace{1em} We first show that \( f \) is one-to-one. Let \( a, b \in A \) such that \( f(a) = f(b) \). Now

\[
\begin{align*}
a &= i_A(a) = (f \circ f)(a) = f(f(a)) = f(f(b)) \\
&= (f \circ f)(b) = i_A(b) = b.
\end{align*}
\]

Thus, \( f \) is one-to-one.

Next, we show that \( f \) is onto. Let \( c \in A \). We show that there exists \( x \in A \) such that \( f(x) = c \). Suppose that \( f(c) = d \in A \). Observe that

\[
f(d) = f(f(c)) = (f \circ f)(c) = i_A(c) = c.
\]

Thus, \( f \) is onto.

10.43 \hspace{1em} (a) \hspace{1em} (i) \hspace{1em} \textbf{Direct Proof}. \hspace{1em} Assume that \( g \circ f \) is one-to-one. We show that \( f \) is one-to-one. Let \( f(x) = f(y) \), where \( x, y \in A \). Since \( g(f(x)) = g(f(y)) \), it follows that \( (g \circ f)(x) = (g \circ f)(y) \). Since \( g \circ f \) is one-to-one, \( x = y \).

(ii) \hspace{1em} \textbf{Proof by Contrapositive}. \hspace{1em} Assume that \( f \) is not one-to-one. Hence, there exist distinct elements \( a, b \in A \) such that \( f(a) = f(b) \). Since

\[
(g \circ f)(a) = g(f(a)) = g(f(b)) = (g \circ f)(b),
\]

it follows that \( g \circ f \) is not one-to-one.

(iii) \hspace{1em} \textbf{Proof by Contradiction}. \hspace{1em} Assume, to the contrary, that there exist functions \( f : A \to B \) and \( g : B \to C \) such that \( g \circ f \) is one-to-one and \( f \) is not one-to-one. Since \( f \) is not one-to-one, there exist distinct
elements \( a, b \in A \) such that \( f(a) = f(b) \). However then,
\[
(g \circ f)(a) = g(f(a)) = g(f(b)) = (g \circ f)(b),
\]
contradicting our assumption that \( g \circ f \) is one-to-one.

(b) Let \( A = \{1, 2, 3\}, B = \{w, x, y, z\} \) and \( C = \{a, b, c\} \). Define \( f : A \to B \) by
\[
f = \{(1, w), (2, x), (3, y)\}
\]
and \( g : B \to C \) by
\[
g = \{(w, a), (x, b), (y, c), (z, c)\}.
\]
Then \( g \circ f = \{(1, a), (2, b), (3, c)\} \) is one-to-one, but \( g \) is not one-to-one.

10.45 (a) \((g \circ f)(18, 11) = g(f(18, 11)) = g(29, 18) = (47, 29)\).

(b) The function \( g \circ f : A \times B \to B \times B \) is one-to-one. **Proof** Assume that \((g \circ f)(a, b) = (g \circ f)(c, d)\), where \((a, b), (c, d) \in A \times B \). Then \( g(f(a, b)) = g(f(c, d)) \) and so \( g(a, b) = g(c, d) \). Therefore, \((2a + b, a + b) = (2c + d, c + d)\), which implies that \(2a + b = 2c + d\) and \(a + b = c + d\). Solving these equations, we find that \(a = c\) and \(b = d\); so \((a, b) = (c, d)\). Thus, \( g \circ f \) is one-to-one.

(c) The function \( g \circ f : A \times B \to B \times B \) is onto. **Proof** Let \((m, n) \in B \times B \). Then \( m \) and \( n \) are odd integers. Therefore, \(a = m - n \in A\) and \(b = 2n - m \in B\). Hence, \((g \circ f)(a, b) = g(f(a, b)) = g(f(m - n, 2n - m)) = g(m, n - n) = (m, n)\). Thus, \( g \circ f \) is onto.

10.47 (a) The statement is true. **Proof** Let \( a \in \mathbb{R} \). Suppose that \( f(a) = h, g(b) = c \) and \( h(b) = d \). Then
\[
((g + h) \circ f)(a) = (g + h)(f(a)) = (g + h)b = g(b) + h(b) = c + d; \text{ while } [(g \circ f) + (h \circ f)](a) = (g \circ f)(a) + (h \circ f)(a) = g(f(a)) + h(f(a)) = g(b) + h(b) = c + d. \text{ Therefore, } (g + h) \circ f = (g \circ f) + (h \circ f).
\]
(b) The statement is false. For example, suppose that \( f(x) = x^2, g(x) = x \) and \( h(x) = x \) for \( x \in \mathbb{R} \). So, \((g + h)(x) = 2x\). Then \( [f \circ (g + h)](1) = f((g + h)(1)) = f(2) = 4; \text{ while } [(f \circ g) + (f \circ h)](1) = (f \circ g)(1) + (f \circ h)(1) = f(g(1)) + f(h(1)) = f(1) + f(1) = 1 + 1 = 2. \text{ Thus, } f \circ (g + h) \neq (f \circ g) + (f \circ h) \text{ in general.}
\]

Section 10.5: Inverse Functions

10.49 Let \( f = \{(a, a), (b, a), (c, b)\} \). Then \( f \) is a function from \( A \) to \( A \). But the inverse relation \( f^{-1} = \{(a, a), (a, b), (b, c)\} \) is not a function.

10.51 **Proof** First, we show that \( f \) is one-to-one. Assume that \( f(a) = f(b) \), where \( a, b \in \mathbb{R} - \{3\} \). Then
\[
\frac{5a}{a - 3} = \frac{5b}{b - 3}.
\]
Multiplying both sides by \((a - 3)(b - 3)\), we obtain \(5a(b - 3) = 5b(a - 3)\). Simplifying, we have \(5ab - 15a = 5ab - 15b\). Adding \(-5ab\) to both sides and dividing by \(-15\), we obtain \(a = b\). Thus, \( f \) is one-to-one.

To show that \( f \) is onto, let \( r \in \mathbb{R} - \{5\} \). We show that there exists \( x \in \mathbb{R} - \{3\} \) such that \( f(x) = r \). Consider \( x = \frac{3r}{r - 5}\). (Since \( \frac{3r}{r - 5} \neq 3 \), it follows that \( x \in \mathbb{R} - \{3\} \).) Then
\[
f(x) = f\left(\frac{3r}{r - 5}\right) = \frac{5\left(\frac{3r}{r - 5}\right)}{5 - 3} = \frac{15r}{3r - 15} = \frac{15r}{15} = r,
\]
implying that \( f \) is onto. Therefore \( f \) is bijective.

Since \((f \circ f^{-1})(x) = x\) for all \( x \in \mathbb{R} - \{5\} \), it follows that
\[
(f \circ f^{-1})(x) = f\left(f^{-1}(x)\right) = \frac{5f^{-1}(x)}{f^{-1}(x) - 3} = x.
\]
Thus, \( 5f^{-1}(x) = xf^{-1}(x) - 3 \) and \( 5f^{-1}(x) = xf^{-1}(x) - 3x \). Collecting the terms involving \( f^{-1}(x) \) on the same side of the equation and then factoring \( f^{-1}(x) \) from this expression, we have \( xf^{-1}(x) - 5f^{-1}(x) = 3x \); so
Exercises for Chapter 11  463

\[ f^{-1}(x)(x - 5) = 3x. \] Solving for \( f^{-1}(x) \), we obtain
\[ f^{-1}(x) = \frac{3x}{x - 5}. \]

10.53 Since there are 6 = 3! bijective functions from \( A \) to \( B \), there are 6 functions \( A \) to \( B \) that have inverses.

10.55 (a) The proof is similar to that in Exercise 10.51.
(b) \( f = f^{-1} \).
(c) \( f \circ f \circ f = f \).

10.57 (a) **Proof** Observe that \( f(x) \) ≥ 0 if and only if \( x ≥ 1 \) and that \( f(x) < 0 \) if and only if \( x < 1 \). First, we show that \( f \) is one-to-one. Assume that \( f(a) = f(b) \). We consider two cases.

Case 1. \( f(a) = f(b) ≥ 0 \). Then \( \sqrt{a - 1} = \sqrt{b - 1} \). Squaring both sides, we get \( a - 1 = b - 1 \) and so \( a = b \).

Case 2. \( f(a) = f(b) < 0 \). Then \( \frac{1}{a - 1} = \frac{1}{b - 1} \). Therefore, \( a - 1 = b - 1 \) and so \( a = b \).

Hence, \( f \) is one-to-one. Next, we show that \( f \) is onto. Let \( r \in \mathbb{R} \). We consider two cases.

Case 1. \( r ≥ 0 \). Then \( f(r^2 + 1) = \sqrt{r^2 + 1 - 1} = r \).

Case 2. \( r < 0 \). Then \( f(\frac{r^2 + 1}{r}) = \frac{\sqrt{r^2 + 1} - 1}{r} = r \). Therefore, \( f \) is onto and so \( f \) is a bijection.

(b) \( f^{-1}(x) = \begin{cases} \frac{\sqrt{x + 1} - 1}{2} & \text{if } x < 0 \\ x^2 + 1 & \text{if } x ≥ 0 \end{cases} \)

10.59 **Proof** First, observe that \( g \circ f : A \to C \) and \( h \circ f : A \to C \). Let \( b \in B \). Since \( f \) is bijective, there is a unique element \( a \in A \) such that \( f(a) = b \). Since \( g \circ f = h \circ f \), it follows that \( (g \circ f)(a) = (h \circ f)(a) \) and so \( g(f(a)) = h(f(a)) \). Therefore, \( g(b) = h(b) \) and so \( g = h \).

10.61 (a) \( α^{-1} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 4 & 1 & 6 & 3 & 5 & 2 \end{pmatrix} \) and \( β^{-1} = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 5 & 4 & 2 & 6 & 1 & 3 \end{pmatrix} \).

(b) \( α \circ β = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 5 & 4 & 3 & 6 & 2 & 1 \end{pmatrix} \) and \( β \circ α = \begin{pmatrix} 1 & 2 & 3 & 4 & 5 & 6 \\ 3 & 4 & 2 & 5 & 1 & 6 \end{pmatrix} \).

**EXERCISES FOR CHAPTER 11**

Section 11.1: Numerically Equivalent Sets

11.1 Since \( A_1 = \{-3, -2, 2, 3\}, A_2 = \{-5, -4, -3, 5\}, A_3 = \{-2, -1, 0, 1, 2, 3\}, A_4 = \{-1, 0, 1\} \) and \( A_5 = \{-4, 0, 4\} \), it follows that \(|A_1| = |A_2| = 4, |A_3| = 6 \) and \(|A_4| = |A_5| = 3\). So, the distinct equivalence classes for \( R \) are \([A_1] = \{A_1, A_2\}, [A_3] = \{A_3\} \) and \([A_4] = \{A_4, A_5\}\).

Section 11.2: Denumerable Sets

11.3 **Proof** Since \( A \) and \( B \) are denumerable, the sets \( A \) and \( B \) can be expressed as \( A = \{a_1, a_2, a_3, \ldots \} \) and \( B = \{b_1, b_2, b_3, \ldots \} \).

The function \( f : \mathbb{N} \to A \cup B \) defined by

\[
\begin{array}{cccccccc}
1 & 2 & 3 & 4 & 5 & 6 & \cdots \\
\downarrow & \downarrow & \downarrow & \downarrow & \downarrow & \cdots \\
& a_1 & b_1 & a_2 & b_2 & a_3 & b_3 & \cdots \\
\end{array}
\]

is bijective. Therefore, \( A \cup B \) is denumerable.

11.5 **Proof** Since \( \mathbb{Z} = \{2\} \) is an infinite subset of the denumerable set \( \mathbb{Z} \), it follows by Theorem 11.4 that \( \mathbb{Z} - \{2\} \) is denumerable and so \(|\mathbb{Z}| = |\mathbb{Z} - \{2\}|\).

11.7 (a) \( 1 + \sqrt{2}, (4 + \sqrt{2})/2, (9 + \sqrt{2})/3 \).

(b) **Proof** Assume that \( f(a) = f(b) \), where \( a, b \in \mathbb{N} \). Then \( \sqrt{a^2 + \sqrt{2}} = \sqrt{b^2 + \sqrt{2}} \). Multiplying by \( ab \), we obtain \( a^2b + \sqrt{2}ab = ab^2 + \sqrt{2}a \). Thus, \( a^2b - ab^2 + \sqrt{2}b - \sqrt{2}a = ab(a - b) - \sqrt{2}(a - b) = (a - b)(ab - \sqrt{2}) = 0 \). Therefore, \( a = b \) and \( f \) is one-to-one.
464 Answers to Odd-Numbered Section Exercises

(c) \textbf{Proof} \quad \text{Let } x \in S. \text{ Then } x = (n^2 + \sqrt{2})/n \text{ for some } n \in \mathbb{N}. \text{ Then } f(n) = x. 

(d) Yes, since \( N \) is denumerable and \( f : N \to S \) is a bijection by (b) and (c).

11.9 Let \( A \) be a denumerable set. Then we can write \( A = \{a_1, a_2, a_3, \ldots \}. \) Since \( A_1 = \{a_1, a_3, a_5, \ldots \} \) and \( A_2 = \{a_2, a_4, a_6, \ldots \} \) are denumerable sets, \( \{A_1, A_2\} \) is a partition of \( A \).

11.11 Either \( |A| = |B| \) and \( A \) is denumerable or \( |A| \) is finite. Therefore, the set \( A \) is countable.

11.13 Define \( f : G \to \mathbb{Z} \times \mathbb{Z} \) by \( f(a + bi) = (a, b) \). Then \( f \) is bijective and so \( |G| = |\mathbb{Z} \times \mathbb{Z}| \). Since \( \mathbb{Z} \times \mathbb{Z} \) is denumerable, \( G \) is denumerable.

11.15 Note that \( S \) is an infinite subset of the set \( N \times N \). The result follows by Theorem 11.4 and Result 11.6.

11.17 Since \( A \) is denumerable and \( B \) is an infinite subset of \( A \), it follows that \( B \) is denumerable by Theorem 11.4.

11.19 Let \( A = \{a_1, a_2, a_3, \ldots \} \) be a denumerable set and place the elements of \( A \) in a table, as shown below. For \( i \in N \), let \( A_i \) be the set of elements in the \( i \)th row of the table. In particular,

\[
A_1 = \{a_1, a_3, a_5, \ldots \}, \\
A_2 = \{a_2, a_4, a_6, \ldots \}, \\
A_3 = \{a_4, a_8, a_{12}, \ldots \}.
\]

Then each set \( A_i \) is a denumerable set and \( \{A_1, A_2, A_3, \ldots \} \) is a partition of \( A \) into a denumerable number of denumerable sets.

Section 11.3: Uncountable Sets

11.21 \textbf{Proof} \quad \text{Since the set } C \text{ of complex numbers contains } \mathbb{R} \text{ as a subset and } \mathbb{R} \text{ is uncountable, it follows by Theorem 11.10 that } C \text{ is uncountable.}

11.23 (a) \textbf{Proof} \quad \text{Assume that } f(a) = f(b), \text{ where } a, b \in (0, 1). \text{ Then } 2a = 2b \text{ and so } a = b. \text{ Hence, } f \text{ is one-to-one.}

For each \( r \in (0, 2) \), \( x = r/2 \in (0, 1) \) and \( f(x) = r \). Therefore, \( f \) is onto. Thus, \( f \) is a bijective function from \( (0, 1) \) to \( (0, 2) \).

(b) This follows from (a).

(c) Define the function \( g : (0, 1) \to (a, b) \) by \( g(x) = (b - a)x + a \). Then \( g \) is bijective and so \( (0, 1) \) and \( (a, b) \) have the same cardinality.

11.25 (a) \textbf{Proof} \quad \text{Let } r \in \mathbb{R}. \text{ We show that there is } x \in (-1, 1) \text{ such that } g(x) = r. \text{ If } r = 0, \text{ then } g(0) = 0. \text{ Hence, we may assume that } r \neq 0. \text{ [Solving } g(x) = \frac{r}{1-\sqrt{1+4r^2}} = r \text{ for } x, \text{ we find that } x = (-1 \pm \sqrt{1 + 4r^2})/2r.] \text{ If } r > 0, \text{ then } 0 < -1 + \sqrt{1 + 4r^2} < 2r \text{ and so } (-1 + \sqrt{1 + 4r^2})/2r \in (0, 1). \text{ If } r < 0, \text{ then } 0 < -1 + \sqrt{1 + 4r^2} \text{ and so } -1 < (-1 + \sqrt{1 + 4r^2})/2r < 0. \text{ Thus, } \frac{-1 + \sqrt{1 + 4r^2}}{2r} \in (-1, 0). \text{ Since } g((-1 + \sqrt{1 + 4r^2})/2r) = r, \text{ the function } g \text{ is onto.}

(b) \textbf{Proof} \quad \text{Assume that } g(a) = g(b). \text{ Then } \frac{a}{1-a^2} = \frac{b}{1-b^2} \text{ and so } a(1-b^2) = b(1-a^2). \text{ Simplifying this equation and then factoring, we have } (a-b)(ab+1) = 0. \text{ In order for } ab = -1, \text{ one of } a \text{ and } b \text{ is at least } 1 \text{ or at most } -1. \text{ In either case, this is impossible. Therefore, } ab \neq -1 \text{ and so } a = b. \text{ Hence, } f \text{ is one-to-one.}

(c) Since \( f \) is one-to-one and onto, \( f \) is a bijective function, which implies that \(|(-1, 1)| = |\mathbb{R}|. \text{ Since } \mathbb{R} \text{ is uncountable, so is } (-1, 1).\)

Section 11.4: Comparing Cardinalities of Sets

11.27 Let \( b \in B. \text{ Then the function } f : A \to A \times B \text{ defined by } f(a) = (a, b) \text{ for each } a \in A \text{ is one-to-one. Thus, } |A| \leq |A \times B|.

11.29 The cardinalities of these sets are the same. Consider \( f : [0, 1] \to [1, 3] \) defined by \( f(x) = 2x + 1 \) for all \( x \in [0, 1]. \)
11.31  The statement is true. **Proof**  Let $A$ be a set. Then $A$ is finite, denumerable or uncountable. If $A$ is finite, say $|A| = n \in \mathbb{Z}, n \geq 0$, then $|2^A| = 2^n$ and so $2^A$ is a finite set. If $A$ is denumerable, then since $|2^A| > |A|$, $2^A$ is not denumerable. If $A$ is uncountable, then since $|2^A| > |A|$, $2^A$ is also an uncountable set.

### Section 11.5: The Schröder–Bernstein Theorem

11.33  **Proof**  Since $(0, 1) \subseteq [0, 1]$, the function $i : (0, 1) \rightarrow [0, 1]$ defined by $i(x) = x$ is an injective function. The function $f : [0, 1] \rightarrow (0, 1)$ defined by $f(x) = \frac{1}{2}x + \frac{1}{4}$ is also injective. It then follows by the Schröder–Bernstein Theorem that $|(0, 1)| = |[0, 1]|$.

11.35  **Proof**  Since the function $f : \mathbb{R}^+ \rightarrow \mathbb{R}$ defined by $f(x) = x$ is one-to-one, it follows that $|\mathbb{R}^+| \leq |\mathbb{R}|$. By Corollary 11.15, the sets $(0, 1)$ and $\mathbb{R}$ are numerically equivalent and so there exists a bijective function $g : \mathbb{R} \rightarrow (0, 1)$. This function can be used to define a one-to-one function $h : \mathbb{R} \rightarrow \mathbb{R}^+$ where $h(x) = g(x)$ for each $x \in \mathbb{R}$. Thus, $|\mathbb{R}| \leq |\mathbb{R}^+|$. By Theorem 11.20, $|\mathbb{R}^+| = |\mathbb{R}|$.

11.37  **(a) Proof**  Assume that $f(m/n) = f(r/s)$. Since $f(m/n)$ has $2k$ digits for some integer $k \geq 2$, the integer $f(m/n)$ contains at least $k$ consecutive 0’s. Then the digits to the rightmost block of $k$ consecutive 0’s make up $n$ while the digits to the left of this block make up $m$. Since $f(r/s) = f(m/n)$, it follows by the same argument that $r = m$ and $s = n$. So, $m/n = r/s$.

**Proof** (b) The function $g : \mathbb{N} \rightarrow \mathbb{Q}^+$ defined by $g(n) = n$ is injective. Combining this with the function $f$ in (a) gives us, by the Schröder–Bernstein Theorem, $|\mathbb{Q}^+| = |\mathbb{N}|$ and so $\mathbb{Q}^+$ is denumerable.

### EXERCISES FOR CHAPTER 12

#### Section 12.1: Divisibility Properties of Integers

12.1  **Proof**  Assume that $a | b$ and $c | d$. Then $b = ax$ and $d = cy$ for integers $x$ and $y$. Then $ad + bc = a(cy) + (ax)c = ac(y + x)$. Since $x + y$ is an integer, $ac | (ad + bc)$.

12.2  **Proof**  Assume that $ac | bc$. Then $bc = (ac)x = c(ax)$ for some integer $x$. Since $c \neq 0$, we can divide by $c$, obtaining $b = ax$. So, $a | b$.

12.3  **Proof**  Assume, to the contrary, that there exists a prime $n \geq 3$ that can be expressed as $k^3 + 1 \geq 3$ for some integer $k$. Since $n = k^3 + 1 = (k + 1)(k^2 - k + 1)$, it follows that $k + 1 = 1$ or $k^2 - k + 1 = 1$, which implies that $k = 0$ or $k = 1$. Thus, $n = 1$ or $n = 2$, which is a contradiction.

12.4  **Proof**  We employ induction. For $n = 1$, we have $5^{2^1} + 7 = 32$ and $8 | 32$. Thus, the result is true for $n = 1$.

Assume that

$$8 \mid (5^{2^k} + 7)$$

for some positive integer $k$. We show that

$$8 \mid (5^{2^{k+1}} + 7).$$

Since $8 \mid (5^{2^k} + 7)$, it follows that $5^{2^k} + 7 = 8a$ for some integer $a$ and so $5^{2^k} = 8a - 7$. Thus,

$$5^{2^{k+1}} + 7 = 5^2 \cdot 5^{2^k} + 7 = 25(8a - 7) + 7 = 200a - 175 + 7 = 200a - 168 = 8(25a - 21).$$

Since $25a - 21$ is an integer, $8 \mid (5^{2^{k+1}} + 7)$. The result then follows by the Principle of Mathematical Induction.

12.9  **Proof**  Consider the numbers $2 + (n + 1)!$, $3 + (n + 1)!$, $\ldots$, $n + (n + 1)!$, $(n + 1) + (n + 1)!$. Observe for each integer $k$ with $2 \leq k \leq n + 1$ that $k$ divides $k + (n + 1)!$. Thus, these $n$ numbers are composite.

12.10 **Proof**  Since $d | a_i$ for $i = 1, 2, \ldots, n$, there exist integers $d_i, (1 \leq i \leq n)$ such that $a_i = dd_i$. Thus,

$$\sum_{i=1}^{n} a_i x_i = \sum_{i=1}^{n} (dd_i) x_i = d \sum_{i=1}^{n} d_i x_i.$$ 

Since $\sum_{i=1}^{n} d_i x_i$ is an integer, $d | \sum_{i=1}^{n} a_i x_i$. 

Answers to Odd-Numbered Section Exercises

12.13 (a) Let \( a_1, a_2, \ldots, a_k \) be the distinct positive integers that divide \( n \). Then \( a_1, a_2, \ldots, a_k, 2a_1, 2a_2, \ldots, 2a_k \) divide \( 2n \). So, \( 2k \) integers divide \( 2n \). In addition to these \( 2k \) integers, \( 4a_1, 4a_2, \ldots, 4a_k \) also divide \( 4n \). So, \( 3k \) integers divide \( 4n \).

(b) Let \( a_1, a_2, \ldots, a_k \) be the distinct positive integers that divide \( n \). Then \( a_1, a_2, \ldots, a_k, 3a_1, 3a_2, \ldots, 3a_k \) divide \( 3n \). In addition to these \( 2k \) integers, \( 9a_1, 9a_2, \ldots, 9a_k \) also divide \( 9n \). So, \( 3k \) integers divide \( 9n \).

(c) Let \( n \) be a positive integer and let \( p \) be a prime such that \( p \mid n \). If \( k \) integers divide \( n \), how many integers divide \( pn \)? How many integers divide \( p^n \), where \( a \in \mathbb{N} \)? Answer: \((a + 1)k\).

Section 12.2: The Division Algorithm

12.15 (a) \( 125 = 17 \cdot 7 + 6 \) (\( q = 7, r = 6 \))

(b) \( 125 = (-17) \cdot (-7) + 6 \) (\( q = -7, r = 6 \))

(c) \( 96 = 8 \cdot 12 + 0 \) (\( q = 12, r = 0 \))

(d) \( 96 = (-8) \cdot (-12) + 0 \) (\( q = -12, r = 0 \))

(e) \(-17 = 22 \cdot (-1) + 5 \) (\( q = -1, r = 5 \))

(f) \(-17 = (-22) \cdot 1 + 5 \) (\( q = 1, r = 5 \))

(g) \( 0 = 15 \cdot 0 + 0 \) (\( q = 0, r = 0 \))

(h) \( 0 = (-15) \cdot 0 + 0 \) (\( q = 0, r = 0 \))

12.17 (a) **Proof** Let \( p \) be an odd prime. Then \( p = 2a + 1 \) for some integer \( a \). We consider two cases, depending on whether \( a \) is even or \( a \) is odd.

Case 1. \( a \) is even. Then \( a = 2k \), where \( k \in \mathbb{Z} \). Thus, \( p = 2a + 1 = 2(2k) + 1 = 4k + 1 \).

Case 2. \( a \) is odd. Then \( a = 2k + 1 \), where \( k \in \mathbb{Z} \). Thus, \( p = 2a + 1 = 2(2k + 1) + 1 = 4k + 3 \).

(b) **Proof** Let \( p \geq 5 \) be an odd prime. Then \( p = 2a + 1 \) for some integer \( a \). We consider three cases, depending on whether \( a = 3k \), \( a = 3k + 1 \) or \( a = 3k + 2 \) for some integer \( k \).

Case 1. \( a = 3k \). Then \( p = 2a + 1 = 2(3k) + 1 = 6k + 1 \).

Case 2. \( a = 3k + 1 \). Then \( p = 2a + 1 = 2(3k + 1) + 1 = 6k + 3 \).

Case 3. \( a = 3k + 2 \). Then \( p = 2a + 1 = 2(3k + 2) + 1 = 6k + 5 \).

12.19 (a) Observe that \( n = 6q + 5 = 3(2q) + 3 = 2(2q + 1) + 2 \). Letting \( k = 2q + 1 \), we see that \( n = 3k + 2 \).

(b) The converse is false. The integer \( 2 = 3 \cdot 0 + 2 \) is of the form \( 3k + 2 \), but \( 2 \) is not of the form \( 6q + 5 \) since \( \exists p \mid 6q + 1 \).

12.21 **Proof** Let \( a \) be an odd integer. Then \( a = 2b + 1 \) for some integer \( b \). Thus,

\[ a^2 = (2b + 1)^2 = 4b^2 + 4b + 1 = (2b^2 + 2b + 1). \]

Since \( k = b^2 + b \) is an integer, \( a = 4k + 1 \).

12.23 **Result** The square of an integer that is not a multiple of 5 is either of the form \( 5k + 1 \) or \( 5k + 4 \) for some integer \( k \).

**Proof** Let \( n \) be an integer that is not a multiple of 5. Then \( n = 5q + r \) for some integers \( q \) and \( r \) with \( 1 \leq r \leq 4 \). We consider these four cases.

Case 1. \( n = 5q + 1 \). Then

\[ n^2 = (5q + 1)^2 = 25q^2 + 10q + 1 = 5(5q^2 + 2q) + 1, \]

where \( k = 5q^2 + 2q \in \mathbb{Z} \).

(The other three cases are handled similarly.)

12.25 **Proof** We proceed by induction. By Result 4.11, the statement is true for \( n = 2 \). Assume that if \( a_1, a_2, \ldots, a_k \) are \( k \geq 2 \) integers such that \( a_i \equiv 1 \pmod{3} \) for each \( i \), then \( a_1a_2 \cdots a_k \equiv 1 \pmod{3} \). Now let \( b_1, b_2, \ldots, b_{k+1} \) be \( k + 1 \) integers such that \( b_i \equiv 1 \pmod{3} \) for all \( i \). We show that \( b_1b_2 \cdots b_{k+1} \equiv 1 \pmod{3} \). Let \( b = b_1b_2 \cdots b_k \). By the induction hypothesis, \( b \equiv 1 \pmod{3} \). Since \( b \equiv 1 \pmod{3} \), \( b \equiv 1 \pmod{3} \), the result follows by Result 4.11 that \( b_1b_2 \cdots b_{k+1} = bb_{k+1} \equiv 1 \pmod{3} \). The result then follows by the Principle of Mathematical Induction.

12.27 The statement is true. **Proof** Since \( a \) and \( b \) are odd integers, \( a = 2x + 1 \) and \( b = 2y + 1 \), where \( x, y \in \mathbb{Z} \). If \( 4 \mid (a - b) \), then we have the desired result. Thus, we may assume that \( 4 \nmid (a - b) \). Then \( a - b = 2(x - y) \),
where \( x - y \) is an odd integer. Let \( x - y = 2z + 1 \), where \( z \in \mathbb{Z} \). Thus, \( a = b + 2(x - y) = b + 4z + 2 \) and
\[
a + b = 2b + 4z + 2 = 2(2y + 1) + 4z + 2 = 4y + z + 1.
\]
Since \( y + z + 1 \in \mathbb{Z} \), it follows that \( 4 \mid (a + b) \).

**12.29** (a) **Proof**  Let \( x, y \in \mathbb{N} \) and let \( a = 2x^2 + y^2, b = 2c^2, c = 2xy \) and \( d = y^2 \). Then
\[
a^2 = (2x^2 + y^2)^2 = 4x^4 + 4x^2y^2 + y^4 = b^2 + c^2 + d^2.
\]

(b) **Proof**  Let \( x \in \mathbb{N} \) and let \( a = 2x \) and \( b = c = d = e = x \). Then
\[
a^2 = 4x^2 = x^2 + x^2 + x^2 + x^2 = b^2 + c^2 + d^2 + e^2.
\]

[Note: Observe that for \( x \in \mathbb{N} \), \( (4x^2) = (x)^2 + (x)^2 + (x)^2 + (x)^2 = (2x)^2 + (3x)^2 \), \( (5x)^2 = (x)^2 + (x)^2 + (x)^2 + (2x)^2 + (3x)^2 \) and \( (6x)^2 = (x)^2 + (x)^2 + (x)^2 + (2x)^2 + (2x)^2 + (3x)^2 + (4x)^2 \).]

**12.31** (a) \( S_z \) is a set of positive odd integers.

(b) \( 14 \in S_{13} \).

(c) \( 16 \in S_1 \).

(d) The statement is true. **Proof**  Let \( n \geq 2 \) be an integer. Since \( n \geq 2 \), the integer \( n \) is either prime or composite. We consider these two cases.

**Case 1.** \( n \) is prime. Consider the set \( S = \{ n^i + 1 : k \in \mathbb{N} \} \). Since \( n \) is a prime, \( n \) is the smallest positive integer such that when any element of \( S \) is divided by \( n \), a remainder of 1 results. Since \( S \) is an infinite set and \( S \subseteq S_n \), it follows that \( S_n \) is infinite.

**Case 2.** \( n \) is composite. Let \( m \) be any integer that results in a remainder of 1 when divided by \( n \). Then \( m = nq + 1 \) for some integer \( q \). Since \( n \) is composite, it follows by the Lemma 12.1 that there are integers \( a \) and \( b \) with 1 < \( a < n \) and 1 < \( b < n \) such that \( n = ab \). Then \( m = a(bq) + 1 \). Hence, when \( m \) is divided by \( a \), a remainder 1 results and so \( m \notin S_n \). Consequently, \( S_n = \emptyset \).

**Section 12.3: Greatest Common Divisors**

**12.33** \( S = \{ 2 \cdot 3 \cdot 5, 2 \cdot 3 \cdot 7, 2 \cdot 5 \cdot 7, 3 \cdot 5 \cdot 7 \} \).

**12.35** **Proof**  Let gcd\( (ka, kb) = e \). We show that \( e = kd \). Since \( d \mid a \) and \( d \mid b \), it follows that \( a = dr \) and \( b = ds \) for integers \( r \) and \( s \). Then \( ka = (kd)r \) and \( kb = (kd)s \). Since \( r \) and \( s \) are integers, \( kd \mid ka \) and \( kd \mid kb \). Because \( e \) is the greatest positive integer that divides both \( ka \) and \( kb \), we have \( kd \leq e \). Also, there exist integers \( x \) and \( y \) such that \( d = ax + by \) and so \( kd = (ka)x + (kb)y \). Since \( e \mid ka \) and \( e \mid kb \), it follows that \( e \mid kd \) and so \( e \leq kd \).

Therefore, \( e = kd \).

**Section 12.4: The Euclidean Algorithm**

**12.37** (a) gcd\( (51, 288) = 3 \).  (b) gcd\( (357, 629) = 17 \).  (c) gcd\( (180, 252) = 36 \).

**12.39** Observe that if \( d = as + bt \) and \( k \in \mathbb{Z} \), then \( d = a(s + kb) + b(t - ka) \).

**12.41** Since \( n \mid (7m + 3) \), it follows that \( n \mid 5(7m + 3) \). Hence, \( n \mid [(35m + 26) - (35m + 15)] \). Thus, \( n = 11 \).

**12.43** **Proof**  Since \( a \equiv b \) (mod \( m \)) and \( a \equiv c \) (mod \( n \)), it follows that \( a = b + mx \) and \( a = c + ny \) for some integers \( x \) and \( y \). Hence, \( b + mx = c + ny \) and so \( b - c = ny - mx \). Since \( d = \text{gcd}(m, n) \), it follows that \( d \mid m \) and \( d \mid n \).

Thus, \( m = dr \) and \( n = ds \), where \( r, s \in \mathbb{Z} \). Therefore,
\[
-b - c = ny - mx = (ds)y - (dr)x = d(sy - rx).
\]

Since \( sy - rx \) is an integer, \( d \mid (b - c) \) and so \( b \equiv c \) (mod \( d \)).

**12.45** Since gcd\( (a, b) = \text{gcd}(r_{i-1}, r_i) \) and \( r_i \) is a prime number, gcd\( (a, b) \mid r_i \) and so gcd\( (a, b) \) is either \( r_i \) or 1.

**Section 12.5: Relatively Prime Integers**

**12.47** **Proof**  Assume, to the contrary, that \( \sqrt{3} \) is rational. Then \( \sqrt{3} = a/b \), where \( a \) and \( b \) are nonzero integers. We may assume that \( a/b \) has been reduced to lowest terms. Thus, \( a^2 = 3b^2 \). Since \( b^2 \) is an integer, \( 3 \mid a^2 \). It then follows by Corollary 12.14 that \( 3 \mid a \). Thus, \( a = 3x \) for some integer \( x \). So, \( a^2 = (3x)^2 = 3(3x^2) = 3b^2 \) and so \( 3x^2 = b^2 \). Since \( x^2 \) is an integer, \( 3 \mid b^2 \) and so \( 3 \mid b \) by Corollary 12.14. However, \( 3 \) is a common factor of \( a \) and \( b \), contradicting the fact that \( a/b \) has been reduced to lowest terms.
468 Answers to Odd-Numbered Section Exercises

12.49 Proof Assume, to the contrary, that \( p^{1/n} \) is rational. Then \( p^{1/n} = a/b \), where \( a \) and \( b \) are nonzero integers. We may assume that \( a/b \) has been reduced to lowest terms. Thus, \( a^n/b^n = p \) and so \( a^n = pb^n \). Since \( b^n \) is an integer, \( p \mid a^n \). Since \( p \) is a prime, it follows by Corollary 12.15 that \( p \mid a \). Since \( p \mid a \), it follows that \( a = pc \) for some integer \( c \). Thus, \( a^n = (pc)^n = p^n c^n = pb^n \). Hence, \( b^n = p^{-n} c^n = p(p^{-2} c^n) \). Since \( n \geq 2 \), we have that \( p^{-2} c^n \) is an integer and so \( p \mid b^n \). By Corollary 12.15, \( p \mid b \). This contradicts our assumption that \( a/b \) has been reduced to lowest terms.

12.51 (a) Proof Let \( a \) and \( b \) be two consecutive odd positive integers. Then \( a = 2k + 1 \) and \( b = 2k + 3 \) for some integer \( k \). Since

\[
1 = (2k + 1) \cdot (k + 1) + (2k + 3) \cdot (-k)
\]

is a linear combination of \( 2k + 1 \) and \( 2k + 3 \), the integers \( 2k + 1 \) and \( 2k + 3 \) are relatively prime.

(b) One possibility: Every two consecutive integers \( k \) and \( k + 1 \) are relatively prime since 1 can be expressed as a linear combination of \( k \) and \( k + 1 \), namely, \( 1 = (k + 1) \cdot 1 + k \cdot (-1) \). In part (a), we saw that every two consecutive odd positive integers \( a = 2k + 1 \) and \( b = 2k + 3 \) are relatively prime by writing \( 1 = ax + by \), where \( x = k + 1 \) and \( y = -k \). (Note the values of \( x \) and \( y \)) The integers \( a = 3k + 2 \) and \( b = 3k + 5 \) are relatively prime as well since we can write \( 1 = ax + by \), where \( x = 2k + 3 \) and \( y = -(2k + 1) \). (Again, note the values of \( x \) and \( y \).) More generally, we have:

Result For every positive integer \( n \) and every integer \( k \), the integers \( a = nk + (n - 1) \) and
\( b = nk + (2n - 1) \) are relatively prime.

Proof Observe that \( 1 = ax + by \), where \( x = (n - 1)k + (2n - 3) \) and \( y = -(n - 1)k + (n - 2) \).

12.53 Let \( p \) and \( q \) be primes with \( p \geq q \geq 5 \). By Exercise 12.17(b), \( p \) and \( q \) are of the form \( 6k + 1 \) or \( 6k + 5 \) for \( k \in \mathbb{Z} \). Equivalently, \( p = 6a + 1 \) and \( q = 6b + 1 \) for some integers \( a \) and \( b \). Hence,

\[
p^2 - q^2 = (36a^2 + 12a + 1) - (36b^2 + 12b + 1) = 12(3a^2 + a) - 12(3b^2 + b).
\]

By Theorem 3.12, \( a^2 \) and \( a \) (and \( b^2 \) and \( b \)) are of the same parity. Thus, \( 3a^2 + a \) and \( 3b^2 + b \) are both even and we can write \( p^2 - q^2 = 24k \) for some integer \( k \).

12.55 Proof Assume that \( a \equiv b \mod m \) and \( a \equiv b \mod n \), where gcd\((m, n) = 1 \). Thus, \( m \mid (a - b) \) and \( n \mid (a - b) \). By Theorem 12.16, \( mn \mid (a - b) \). Hence, \( a \equiv b \mod mn \).

12.57 Claim: gcd\((x, y) = d \) if and only if \( d \leq 1 \).

Proof Let \( d = \gcd(a, b) \). Then there exist integers \( x \) and \( y \) such that \( d = ax + by \). We show that \( \gcd(x, y) = 1 \). Suppose that \( \gcd(x, y) = e \). Since \( d \mid a \) and \( d \mid b \), there exist integers \( r \) and \( s \) such that \( a = dr \) and \( b = ds \). Because \( e \mid x \) and \( e \mid y \), there exist integers \( w \) and \( z \) such that \( x = ew \) and \( y = ez \). Therefore, \( d = ax + by = (dr)(ew) + (ds)(ez) = de(rw) + de(sz) \). So, \( 1 = e(rw + sz) \). Since \( rw + sz \) is an integer, \( e = 1 \).

12.59 (a) Proof Assume that \( a \mid c \) and \( b \mid c \), where \( \text{gcd}(a, b) = d \). Then there exist integers \( x \) and \( y \) such that \( d = ax + by \). Hence, \( cd = axc + bcy \). Because \( a \mid c \) and \( b \mid c \), there exist integers \( r \) and \( s \) such that \( c = ar \) and \( c = bs \). Hence, \( cd = a(bs)x + b(ar)y = ab(sx) + ab(sy) = ab(sx + sy) \). Since \( sx + sy \) is an integer, \( ab \mid cd \).

(b) Let \( a, b, c \in \mathbb{Z} \) such that \( a \mid c \) and \( b \mid c \) and \( a \) and \( b \) are relatively prime. Then \( \text{gcd}(a, b) = 1 \). Letting \( d = 1 \) in (a), we obtain Theorem 12.16.

12.61 (a) \( m = 5, n = 6 \).

(b) Consider the pairs \( \{m, n\} = \{4, 9\}, \{4, 6\}, \{9, 15\} \).

Section 12.6: The Fundamental Theorem of Arithmetic

12.63 (a) \( 4725 = 3^2 \cdot 5^2 \cdot 7 \) (b) \( 9702 = 2 \cdot 3^2 \cdot 7^2 \cdot 11 \) (c) \( 180625 = 5^4 \cdot 17^2 \).

12.65 (a) \( 4278 = 2 \cdot 3 \cdot 23 \cdot 31 \) and \( 71929 = 11 \cdot 13 \cdot 503 \).

(b) \( \text{gcd}(4278, 71929) = 1 \)

12.67 Proof Assume, to the contrary, that the number of primes is finite. Let \( P = \{p_1, p_2, \ldots, p_n\} \) be the set of all primes, where \( p_1 < p_2 < \cdots < p_n \). Let \( m = p_n! + 1 \). Then \( m \geq p_n + 1 \) and so \( m \) is not a prime. Since \( m \) has a prime factor and every prime belongs to \( P \), there is a prime \( p_i \) (\( 1 \leq i \leq n \)) such that \( p_i \mid m \). Hence, \( m = p_k k \) for some integer \( k \). Since \( p_i \) is a factor of \( p_n! \) and \( 1 = m = p_k k \), it follows that \( p_i \mid 1 \), which is a contradiction.
12.69 **Proof** Let \( d = p_1^{c_1} p_2^{c_2} \cdots p_r^{c_r} \). We show that \( \gcd(m, n) = d \). Since \( c_i \leq a_i \) and \( c_i \leq b_i \) for each \( 1 \leq i \leq r \), it follows that \( d \mid m \) and \( d \mid n \). We claim that \( \gcd(m, n) \) can be expressed as \( p_1^{c_1} p_2^{c_2} \cdots p_r^{c_r} \) for nonnegative integers \( k_i \) (\( 1 \leq i \leq r \)). Suppose that some prime \( p \) distinct from \( p_1, p_2, \ldots, p_r \) divides \( d \). Then \( p \mid m \) and \( p \mid n \), which is impossible. Thus, as claimed, \( \gcd(m, n) \) can be expressed as \( p_1^{c_1} p_2^{c_2} \cdots p_r^{c_r} \) for nonnegative integers \( k_i \) (\( 1 \leq i \leq r \)).

If \( d \neq p_1^{c_1} p_2^{c_2} \cdots p_r^{c_r} \), then \( p_1^{k_1} p_2^{k_2} \cdots p_r^{k_r} > p_1^{c_1} p_2^{c_2} \cdots p_r^{c_r} \), which implies that \( p_1^{k_1} > p_i^{k_i} \) for some \( s \) (\( 1 \leq s \leq r \)). Then \( k_s > c_s \) and so \( p_1^{k_1} \nmid m \) or \( p_i^{k_i} \nmid n \), a contradiction. ■

### Section 12.7: Concepts Involving Sums of Divisors

12.71 **Proof** Let \( k \) be the maximum number of distinct positive integers whose sum is \( n \). Since the \( k \) smallest distinct positive integers are 1, 2, \ldots, \( k \), it follows that \( 1 + 2 + \cdots + k \leq n \). Therefore, \( k \) is the largest integer such that \( k(k + 1)/2 \leq n \) and so \( k^2 + k - 2n \leq 0 \). Hence, \( k \) is the largest integer that is at most \((\sqrt{1 + 8n} - 1)/2 \). That is, 

\[
k = \left\lfloor (\sqrt{1 + 8n} - 1)/2 \right\rfloor.
\]

### EXERCISES FOR CHAPTER 13

#### Section 13.1: The Multiplication and Addition Principles

13.1 By the Multiplication Principle, there are \( 5 \cdot 4 \cdot 2 \cdot 3 = 120 \) ways to travel from A to B by passing through B, C and D in that order.

13.3 (a) **Proof** We proceed by induction. We have already seen for two finite sets \( A \) and \( B \) that \( |A \times B| = |A| \cdot |B| \).

Assume for an integer \( k \geq 2 \) that for any \( k \) finite sets \( B_1, B_2, \ldots, B_k \), we have \( |B_1 \times B_2 \times \cdots \times B_k| = |B_1| \cdot |B_2| \cdots |B_k| \).

Let \( A_1, A_2, \ldots, A_{k+1} \) be \( k + 1 \) finite sets and let \( A = A_1 \times A_2 \times \cdots \times A_{k+1} \). Applying the induction hypothesis, we have

\[
|A_1 \times A_2 \times \cdots \times A_{k+1}| = |(A_1 \times A_2 \times \cdots \times A_k) \times A_{k+1}|
\]

\[
= |A_1 \times A_2 \times \cdots \times A_k| \cdot |A_{k+1}|
\]

\[
= |A_1| \cdot |A_2| \cdots |A_k| \cdot |A_{k+1}|.
\]

The result then follows by the Principle of Mathematical Induction. ■

(b) \( m! \).

13.5 Assume that \( A = \{a_1, a_2, \ldots, a_m\} \).

(a) For a function \( f : A \to B \), there are \( n \) choices for \( f(a_i) \) for \( i = 1, 2, \ldots, m \). Thus, the total number of such functions is \( n \cdot n \cdot \cdots \cdot n \) (\( m \) terms in the product) or \( n^m \).

(b) For a one-to-one function \( f : A \to B \), there are \( n \) choices for \( f(a_1) \). Once the value of \( f(a_1) \) has been chosen, there are \( n - 1 \) choices for \( f(a_2) \). In general, for \( 1 \leq i \leq m \), there are \( n - i + 1 \) choices for \( f(a_i) \).

Thus, the total number of one-to-one functions from \( A \) to \( B \) is \( n(n - 1)(n - 2) \cdots (n - m + 1) \).

(c) If \( m > n \), then \( |A| > |B| \) and there are no one-to-one functions from \( A \) to \( B \).

13.7 Since the sets \( A_{ij} \), \( 1 \leq i, j \leq 5 \), are pairwise disjoint, it follows by the Addition Principle that

\[
|A| = \sum_{j=1}^{5} \left( \sum_{i=1}^{5} |A_{ij}| \right) = \sum_{j=1}^{5} \left( \sum_{i=1}^{5} (i + j) \right)
\]

\[
= \sum_{j=1}^{5} (15 + 5j) = 5 \cdot 15 + 5 \sum_{j=1}^{5} j = 5 \cdot 15 + 5 \cdot 15 = 150.
\]

13.9 The proof is similar to that given in Exercise 13.3.

13.11 (a) Since there are two possible outcomes for each term of the sequence, there are \( 2^n \) possible sequences.

(b) Since heads must occur in exactly one of \( n \) terms (with tails in all other terms), there are \( n \) ways in which heads can occur exactly once.

(c) Since heads occurring exactly \( n - 1 \) times is equivalent to tails occurring exactly once, by an argument similar to (b), it follows that there are \( n \) ways in which heads can occur exactly \( n - 1 \) times.
Answers to Odd-Numbered Section Exercises

(d) For heads to occur at most once, it must occur exactly once or not at all. By (b), there are \( n \) ways in which heads can occur exactly once. There is only one way for heads not to occur. By the Addition Principle, there are \( n + 1 \) ways in which heads can occur at most once.

Section 13.2: The Principle of Inclusion-Exclusion

13.13 (a) Let \( A \) be the set of \((2n)\)-bit strings beginning with \( n \) 0s and let \( B \) be the set of \((2n)\)-bit strings ending with \( n \) 0s. There is only one \((2n)\)-bit string beginning and ending with \( n \) 0s and so \( |A \cap B| = 1 \). Then
\[
|A \cup B| = |A| + |B| - |A \cap B| = 2^n + 2^n - 1 = 2^n - 1 = 2^n - 1.
\]
(b) These are all \((2n)\)-bit strings except those occurring in (a). Hence, this number is \( 2^n - (2^n - 1) = 2^n - 2^n + 1 = (2^n - 1)^2 \).

13.15 Let \( S \) be the set of bijective functions from \([1, 2, 3] \) to \([1, 2, 3] \). Then \( |S| = 3! = 6 \). For \( i = 1, 2, 3 \), let \( S_i \) be the set of bijective functions \( f : [1, 2, 3] \rightarrow [1, 2, 3] \) for which \( f(i) = i \). Thus, \( S_i \) is the set of bijective functions \( f : [1, 2, 3] \rightarrow [1, 2, 3] \) for which \( f(i) \neq i \). Then the number of bijective functions \( f : [1, 2, 3] \rightarrow [1, 2, 3] \) for which \( f(i) \neq i \) for \( i = 1, 2, 3 \) is \( S_1 \cap S_2 \cap S_3 = S_1 \cup S_2 \cup S_3 = |S| - |S_1 \cup S_2 \cup S_3| \). Since \( |S| = 2 \) for \( i = 1, 2, 3 \) and \( |S_i \cap S_j| = |S_1 \cap S_2 \cap S_3| = 1 \) for \( i, j \in \{1, 2, 3\} \) and \( i \neq j \), it follows by the Principle of Inclusion-Exclusion that \( |S_1 \cap S_2 \cap S_3| = 3 \cdot 2 - 3 \cdot 1 + 1 = 4 \) and so \( |S| - |S_1 \cup S_2 \cup S_3| = 2 \).

13.17 By the Principle of Inclusion-Exclusion,
\[
|A_1 \cup A_2 \cup A_3| = |A_1| + |A_2| + |A_3| - |A_1 \cap A_2| - |A_1 \cap A_3| - |A_2 \cap A_3| + |A_1 \cap A_2 \cap A_3|
\]
\[
= 3 \cdot 99^{100} - 3 \cdot 98^{100} + 97^{100}.
\]

13.19 First, observe that \( 10^{30} = (2 \cdot 5)^{30} = 2^{30}5^{30} \). Let
\[
A = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect square} \}
\]
\[
B = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect cube} \}
\]
\[
C = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect fifth power} \}.
\]
Then
\[
A \cap B = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect 6th power} \}
\]
\[
A \cap C = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect 10th power} \}
\]
\[
B \cap C = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect 15th power} \}
\]
\[
A \cap B \cap C = \{ n \in \mathbb{Z} : 1 \leq n \leq 10^{30} \text{ and } n \text{ is a perfect 30th power} \}.
\]
Observe that since \( 10^{30} = (10^{15})^2 \), it follows that \( A = \{ n^2 : 1 \leq n \leq 10^{15} \} \), that is, \( |A| = 10^{15} \). Similarly, \( |B| = 10^{10}, |C| = 10^{6}, |A \cap B| = 10^5, |A \cap C| = 10^3, |B \cap C| = 10^2 \) and \( |A \cap B \cap C| = 10^1 \). Thus,
\[
|A \cup B \cup C| = |A| + |B| + |C| - |A \cap B| - |A \cap C| - |B \cap C|
\]
\[
+ |A \cap B \cap C|
\]
\[
= 10^{15} + 10^{10} + 10^6 - 10^5 - 10^3 - 10^2 + 10^1
\]

and so the number of integers \( n \) with \( 1 \leq n \leq 10^{30} \) such that \( n \) is neither a perfect square, perfect cube nor a perfect fifth power is
\[
10^{30} - (10^{15} + 10^{10} + 10^6 - 10^5 - 10^3 - 10^2 + 10^1) = 10^{30} - 10^{15} - 10^{10} - 10^6 + 10^5 + 10^3 + 10^2 - 10^1.
\]

13.21 The task \( T_1 \) can be performed in eight ways, \( T_2 \) can be performed in four ways and \( T_3 \) can be performed in four ways. Furthermore, \( T_1 \) and \( T_2 \) can be performed simultaneously in one way, \( T_1 \) and \( T_3 \) in four ways and \( T_2 \) and \( T_3 \) in one way. Finally, all tasks \( T_1, T_2 \) and \( T_3 \) can be performed simultaneously in one way. By the Principle of Inclusion-Exclusion, the number of ways to perform \( P \) is \( 8 + 4 + 4 - 1 - 4 - 1 + 1 = 11 \).
Section 13.3: The Pigeonhole Principle

13.23 Let $N$ be the population of New York City. Then $N > 7,000,000$. By the Pigeonhole Principle, there are at least

$$\left\lceil \frac{N}{1,000,000} \right\rceil \geq 8 \text{ people in the city with the same number of hairs on their heads.}$$

13.25 (a) **Proof** Let $T = \{n_1, n_2, \ldots, n_{51}\}$ be a set of 51 integers selected from $S$. Then we can write $n_i = 2^a b_i$, where $a_i$ is a nonnegative integer and $b_i$ is odd for each $i$ ($1 \leq i \leq 51$). Since $1 \leq b_i \leq n_i$ for each integer $i$ ($1 \leq i \leq 51$), it follows that $b_i \in S$ for each $i$. Because $S$ contains only 50 odd integers, it follows by the Pigeonhole Principle that there are integers $r$ and $s$ with $r \neq s$ such that $b_r = b_s$. Since $a_r \neq a_s$, we may assume that $a_r < a_s$. Then $n_r = 2^a b_r$ and $n_s = 2^a b_s$ and so $n_r \neq n_s$.

(b) For every two integers in $\{51, 52, \ldots, 100\}$, neither is divisible by the other.

13.27 Since there are six pairs of these cities, it follows by the Pigeonhole Principle that there is at least one pair where the distance between these two cities is at least $\lceil 103/6 \rceil = 18$ miles.

13.29 **Proof** Let $B = \{b_1, b_2, \ldots, b_n\}$. Then $m = |f^{-1}\{|b_1\}| + |f^{-1}\{|b_2\}| + \cdots + |f^{-1}\{|b_n\}| \geq k + 1$. By the Pigeonhole Principle, $|f^{-1}\{|b_i\}| \geq \lceil nk + 1/n \rceil = k + 1$ for some $i$ ($1 \leq i \leq n$).

13.31 **Proof** For $k = 1, 2, \ldots, n$, let $s_k = x_1 + x_2 + \cdots + x_k$. By the Division Algorithm (Theorem 12.4), there exist integers $q_k$ and $r_k$ with $0 \leq r_k \leq n - 1$ such that $s_k = nq_k + r_k$. If $r_k = 0$ for some $k$ in $\{1, 2, \ldots, n\}$, then $s_k = x_1 + x_2 + \cdots + x_k \equiv 0 \pmod{n}$. On the other hand, if $r_k \neq 0$ for all $k \in \{1, 2, \ldots, n\}$, then, by the Pigeonhole Principle, there exist integers $i, j \in \{1, 2, \ldots, n\}$ with $i < j$ such that $r_i = r_j$. Then

$$s_j - s_i = (nq_j + r_j) - (nq_i + r_i) = n(q_j - q_i),$$

Therefore, $x_{i+1} + x_{i+2} + \cdots + x_j \equiv 0 \pmod{n}$.

13.33 **Proof** Consider the first 1100 such integers $R_1, R_2, \ldots, R_{1100}$. Since there are 1099 possible remainders when these 1100 integers are divided by 1099, it follows by the Pigeonhole Principle that there exist integers $i$ and $j$ with $1 \leq i < j \leq 100$ such that $R_i$ and $R_j$ have the same remainder when divided by 1099. Thus, $R_j - R_i = 1099q$ for some positive integer $q$. Now $R_j - R_i = 11 \cdots 10 \cdots 0$ where $j - i$ digits are 1s and $i$ digits are 0s. Thus, $R_j - R_i = 10^{j-i} 999999 \cdots$. Since $\gcd(1099, 10^n) = 1$, it follows by Theorem 12.13 that $1099 \mid R_{j-i}$.

13.35 (a) **Proof** There exist two distinct powers $7^m$ and $7^n$ that have the same remainder when divided by 1000, where $m > n$. Then $7^m \equiv 7^n \pmod{1000}$ and so $7^{m-n} \equiv 1 \pmod{1000}$. Thus, $1000 \mid 7^{m-n} - 1$. Since $\gcd(7^n, 1000) = 1$, it follows by Theorem 12.13 that $1000 \mid 7^{m-n} - 1$. Therefore, $7^{m-n} - 1$ is an integer whose digits end with 000 and so $7^{m-n}$ is an integer whose digits end with 001.

(b) This follows by an argument similar to that in (a).

13.37 **Proof** Suppose that there is no subsequence of $n + 1$ numbers in $s$ that is increasing. For each $k$ with $1 \leq k \leq n + 1$, let $t_k$ denote the length of a longest increasing subsequence of $s$ that begins with $a_k$. Therefore, $t_k \leq n$ for all such $k$. Since $t_1, t_2, \ldots, t_{n+1}$ are $n^2 + 1$ positive integers between 1 and $n$, it follows by the Pigeonhole Principle that at least $\lceil (n^2 + 1)/n \rceil = n + 1$ of these integers are equal, say $t_{k_1} = t_{k_2} = \cdots = t_{k_{n+1}}$, where say $k_1 < k_2 < \cdots < k_{n+1}$. If $a_{k_i} < a_{k_{i+1}}$ for some $i$ with $1 \leq i \leq n$, then any increasing subsequence of length $t_{k_{i+1}}$ beginning with $a_{k_{i+1}}$ will result in an increasing subsequence of length $t_{k_{i+1}} + 1$ beginning with $a_{k_i}$, contradicting the fact that $t_{k_i} = t_{k_{i+1}}$. Thus, $a_{k_1} > a_{k_2} > \cdots > a_{k_{n+1}}$, resulting in a decreasing subsequence of length $n + 1$.

13.39 Since the drawer contains $n_1 = 5$ nickels, $n_2 = 10$ dimes and $n_3 = 25$ quarters, it follows by the Strong Pigeonhole Principle that $1 + (n_1 - 1) + (n_2 - 1) + (n_3 - 1) = 1 + 4 + 9 + 24 = 38$ coins must be removed from the drawer to be certain that all coins of the same denomination have been selected.

Section 13.4: Permutations and Combinations

13.41 (a) This is the number of 8-permutations of $\{1, 2, \ldots, 12\} \setminus \{7, 8\}$, which is $P(10, 8) = 10!/(10 - 8)! = 10!/2$.

(b) First, we determine the number of 8-permutations of $S$ in which 7 and 8 appear consecutively. If 7 is the first term (and 8 is the second term) of the permutation, then the number of such 8-permutations is
472 Answers to Odd-Numbered Section Exercises

\[ P(10, 6) = 10!/(10 - 6)! = 10!/4! = 10!/24. \] There are also 10!/24 such permutations if 8 is the first term and 7 is the second. Thus, the number of 8-permutations in which 7 and 8 are the first two terms is \( 2(10!/24) = 10!/12. \) Since there are seven pairs of consecutive terms in a sequence of length 8, the total number of 8-permutations of \( S \) in which 7 and 8 appear consecutively (in either order) is \( 7(10!/12). \) Since there are \( P(12, 8) = 12!/4! = 12!/24 \) 8-permutations of \( S \), there are \( 12!/24 - 7(10!/12) \) 8-permutations of \( S \) in which 7 and 8 do not appear consecutively in either order.

(c) There are nine possible positions for 6. Since the number of 9-permutations of \( S \) in each case is \( P(11, 8) = 11!/3! = 11!/6, \) there are 9(11!/6) such 9-permutations of \( S. \)

13.43 Let \( A_i \ (i = 2, 3, 5) \) be the set of 15-letter words containing exactly \( i \) distinct vowels. We seek \( |A_2 \cup A_3 \cup A_5| \). Since these sets are pairwise disjoint, it follows by the Addition Principle that \( |A_2 \cup A_3 \cup A_5| = |A_2| + |A_3| + |A_5|. \) First, we compute \( |A_2|. \) There are \( \binom{15}{2} \) = 10 possible locations for two vowels. There are 15 possible locations for one of these vowels and 14 for the other. For each of these pairs of locations, there are \( 2^{13} \) possibilities for the consonants. Since there are seven pairs of consecutive terms in a sequence of length 8, the total number of \( 8\)-permutations of \( S \) in which 7 and 8 appear consecutively (in either order) is \( 7(10!/12). \) Since there are \( P(12, 8) = 12!/4! = 12!/24 \) \( 8\)-permutations of \( S \), there are \( 12!/24 - 7(10!/12) \) \( 8\)-permutations of \( S \) in which 7 and 8 do not appear consecutively in either order.

13.45 (a) The number of 4-element subsets of \( S \) containing \( n \) is \( \binom{n}{4}. \) Therefore, \( \binom{n}{4} = \frac{1}{6} \binom{10}{4}. \) Solving for \( n, \) we obtain \( n = 20. \)

(b) The number of 4-element subsets of \( S \) containing 1 and 2 is \( \binom{n-2}{4}. \) Therefore, \( \binom{n-2}{4} = \frac{1}{2} \binom{10}{4}. \) Solving for \( n, \) we obtain \( n = 12. \)

13.47 Each such \( m\)-permutation of \( S \) consists of the elements of \( A \) and \( m - r \) elements of \( S - A. \) There are \( \binom{\binom{m-r}{m-r}}{\binom{m-r}{m-r}} \) possibilities for each of these \( m - r \) elements. Since there are \( m! \) permutations of the \( m\)-element subset obtained, the total number of \( m\)-permutations of \( S \) containing all elements of \( A \) is \( m! \binom{\binom{m-r}{m-r}}{\binom{m-r}{m-r}}. \)

13.49 (a) This equals the number of ways that \( k \) terms of the sequence can be selected for the occurrence of heads, which is \( \binom{k}{2}. \)

(b) \( \binom{k}{2} + \binom{k}{3} + \cdots + \binom{k}{n}. \)

(c) \( \binom{\binom{k+1}{2}}{\binom{k+1}{2}} + \binom{\binom{k+2}{2}}{\binom{k+2}{2}} + \cdots + \binom{n}{n}. \)

13.51 Proof Using Results 6.4 and 6.5, observe that

\[
\binom{2}{2} + \binom{4}{2} + \binom{6}{2} + \cdots + \binom{2n}{2} = \sum_{k=1}^{n} \binom{2k}{2} = \sum_{k=1}^{n} (2k^2 - k) = 2 \sum_{k=1}^{n} k^2 - \sum_{k=1}^{n} k = 2 \left( \frac{n(n+1)(2n+1)}{6} \right) - \frac{n(n+1)}{2} = \frac{2n(n+1)(2n+1) - 3n(n+1)}{6} = \frac{n(n+1)(4n-1)}{6}. \]

13.53 A 10-permutation of \( A \cup B \cup C \) containing exactly eight elements of \( A \) has two elements from \( B \cup C. \) There are \( C(10, 8)C(14, 2) \) such sets and 10! permutations of each such set, resulting in a total of \( 10!C(10, 8)C(14, 2) \) 10-permutations that contain exactly eight elements of \( A. \)

13.55 (a) Proof We determine the number of ways to choose two disjoint \( r\)-element subsets in an \((n + r)\)-element set \( A. \) One way to obtain two such subsets is to begin with an \( r\)-element subset \( B \) of \( A \) followed by selecting an \( r\)-element subset \( C \) of \( A - B. \) The number of ways of doing this is \( \binom{n+r}{r} \binom{r}{r} = \binom{n+r}{r} \binom{r}{r}. \) Equivalently, we could select a 2r-element subset \( D \) of \( A, \) followed by selecting an \( r\)-element subset \( E \) of \( D. \) The number of ways of doing this is \( \binom{n+r}{2r} \binom{2r}{r} = \binom{n+r}{r} \binom{2r}{r}. \)

(b) Proof We determine the number of ways to choose two disjoint subsets, one with \( r \) elements and the other with \( k \) elements in an \( n\)-element set \( A. \) One way to do this is to select a \((k + r)\)-element subset \( B \) of \( A \) and then select an \( r\)-element subset \( C \) of \( B. \) The number of ways of doing this is \( \binom{n}{k+r} \binom{k+r}{r} = \binom{n}{k+r} \binom{r}{r}. \) Equivalently, we could select a \( r\)-element subset \( D \) of \( A \) followed by selecting a \( k\)-element subset \( E \) of \( A - D. \) The number of ways of doing this is \( \binom{n}{r} \binom{n-r}{k}. \)
Section 13.5: The Pascal Triangle

13.57 (a) \( \binom{3}{0} + \binom{3}{1} = 2^2 \), \( \binom{3}{1} + \binom{3}{2} = 3^2 \) and \( \binom{4}{0} + \binom{4}{1} = 4^2 \).
(b) Observe that \( \binom{n}{0} + \binom{n+1}{1} = \binom{n+1}{2} + \binom{n+1}{n+1} = n^2 \).
(c) Let \( S = \{1, 2, \cdots, 2n + 1\} \). Suppose we wish to determine the number of 2-element subsets of \( S \) that consist of two integers of the same parity. The number of 2-element subsets of \( S \) consisting of two even integers is \( \binom{n}{2} \), while the number of 2-element subsets of \( S \) consisting of two odd integers is \( \binom{n+1}{2} \). Since the number of 2-element subsets of opposite parity is \( n(n+1) \), it follows that \( \binom{n}{2} + \binom{n+1}{2} = \binom{2n+1}{2} - n(n+1) \).

13.59 Proof Since \( k(k-1)(k-2) = 31 \binom{k}{3} \), it follows that
\[
\sum_{k=3}^{n} k(k-1)(k-2) = \sum_{k=3}^{n} 3! \binom{k}{3} = 3! \binom{n+1}{4}
\]
by the Hockey Stick Theorem.

13.61 (a) \( a = b = 6 \) and \( c = 1 \).
(b) Observe that
\[
\sum_{k=1}^{n} k^3 = \sum_{k=1}^{n} \left[ 6 \binom{k}{3} + 6 \binom{k}{2} + \binom{k}{1} \right]
= \sum_{k=3}^{n} 6 \binom{k}{3} + \sum_{k=2}^{n} 6 \binom{k}{2} + \sum_{k=1}^{n} \binom{k}{1}.
\]
By the Hockey Stick Theorem, we have
\[
\sum_{k=1}^{n} k^3 = 6 \binom{n+1}{4} + 6 \binom{n+1}{3} + \binom{n+1}{2} = \frac{n^2(n+1)^2}{4}.
\]
(c) Since \( \binom{n+1}{2} + \binom{n+1}{3} = \binom{n+1}{4} \), it follows by (b) that
\[
6 \binom{n+2}{4} = 6 \binom{n+1}{4} + 6 \binom{n+1}{3} = \frac{n^2(n+1)^2}{4} - \binom{n+1}{2}
= \binom{n+1}{2}^2 - \binom{n+1}{2}.
\]

Section 13.6: The Binomial Theorem

13.63 (a) \( (3x)^4 + 4(3x)^3(-5y) + \binom{4}{2}(3x)^2(-5y)^2 + 4(3x)(-5y)^3 + (-5y)^4 = 81x^4 - 540x^3y + 1350x^2y^2 - 1500xy^3 + 625y^4 \).
(b) \( \binom{6}{2}^2 - \binom{6}{2}^2 + \binom{6}{2}^2 = 480 - 160 + 60 = 380 \).
(c) \( 5 \cdot 2^4 \cdot 3^8 \cdot 5 + 8 \cdot 2^7 \cdot 3^7 = 2^4 \cdot 3^7(75 + 64) = 2^4 \cdot 3^7 \cdot 139 \).
(d) \( \binom{6}{2}^4 = 28 \cdot 4^6 = 2^{14} \cdot 7 \).

13.65 By the Binomial Theorem, \( (1 + r)^n = \sum_{k=0}^{n} \binom{n}{k} r^k \).

13.67 Note that
\[
(1.1)^4 = (1 + .1)^4 = 1^4 + 4(1^3)(.1) + 6(1^2)(.1)^2 + 4(1)(.1)^3 + (.1)^4
= 1 + .4 + .06 + .004 + .0001 = 1.4641.
\]

13.69 (a) Proof Differentiating \( (1 + x)^n = \sum_{k=0}^{n} \binom{n}{k} x^k \), we obtain
\[
(n+1)x^k = \sum_{k=1}^{n} k \binom{n}{k} x^{k-1}.
\]
Substituting \( x = 1 \) in the expression in (1.1) produces \( n2^{n-1} = \sum_{k=1}^{n} k \binom{n}{k} \).
474  Answers to Odd-Numbered Section Exercises

(b) Proof  Substituting $x = -1$ in the expression in (1.1) produces
\[ \sum_{k=0}^{n} (-1)^{k-1} k \binom{n}{k} = 0. \]

(c) Proof  From part (b), \[ \sum_{k=0}^{n} (-1)^{k-1} k \binom{n}{k} = 0. \] Therefore,
\[ \binom{n}{1} - 2 \binom{n}{2} + 3 \binom{n}{3} - 4 \binom{n}{4} + \cdots + (-1)^{n-1} n \binom{n}{n} = 0 \]
and so \( \binom{n}{1} + 3 \binom{n}{3} + \cdots + 2 \binom{n}{2} + 4 \binom{n}{4} + \cdots \).

(d) From part (a),
\[ \sum_{k=0}^{n} (2k+1) \binom{n}{k} = 2 \sum_{k=0}^{n} k \binom{n}{k} + \sum_{k=0}^{n} \binom{n}{k} \]
\[ = 2(n2^{n-1}) + 2^n = (n+1)2^n. \]

13.71 Proof  By the Binomial Theorem,
\[ (a+b)^n = \sum_{k=0}^{n} \binom{n}{k} a^k b^{n-k}. \]
By Exercise 13.70, it follows that \( p\mid \binom{n}{k} \) for every integer \( k \) with \( 1 \leq k \leq p-1 \) and so \( \binom{n}{p} \equiv 0 \pmod{p} \).
Therefore, \( (a+b)^p \equiv a^p + b^p \pmod{p} \).

13.73 (a) Letting \( r = m = n \) in (13.8), we have \( \sum_{k=0}^{n} \binom{n}{k}^2 = \binom{2n}{n} \).

(b) Proof  Since \( \binom{n}{k} = \binom{n}{n-k} \) for every integer \( k \) \( 0 \leq k \leq n \), it follows that
\[ \sum_{k=0}^{n} \binom{n}{k}^2 = \sum_{k=0}^{n} \binom{n}{n-k}^2 = \binom{2n}{n}. \]

(c) Proof  First, recall that \( \binom{n}{k} = 0 \) for integers \( a \) and \( b \) with \( 0 \leq a < b \). Letting \( m = 1 \) in (13.7), we have
\[ \binom{r+1}{r} = \sum_{k=0}^{r} \binom{k}{r-k} = \binom{r}{r} + \binom{r}{r-1}. \]

13.75 Proof  Suppose first that \( a+b = n \) and so \( b = n-a \). By Theorem 13.22, \( \binom{n}{a} = \binom{n}{n-a} = \binom{n}{b} \).
For the converse, assume that \( \binom{n}{a} = \binom{n}{b} \) where \( a < b \). We consider two cases.

Case 1. \( n \) is odd and so \( n = 2r + 1 \) for some integer \( r \). By Exercise 13.74(d),
\[ \binom{n}{a} < \binom{n}{b} \ldots \text{if} \ldots (\binom{n}{a}) > \binom{n}{r+1} > \ldots > \binom{n}{b}. \]
Since \( a < b \) and \( \binom{n}{a} = \binom{n}{b} \), it follows that \( 0 \leq a \leq r \) and \( b \geq r + 1 \). Hence, \( n - b \leq r \), which implies that \( \binom{n}{a} = \binom{n}{b} \) and so \( a = n-b \) or \( a + b = n \).

Case 2. \( n \) is even and so \( n = 2s \) for some integer \( s \). The proof is similar to that in Case 1.

Section 13.7: Permutations and Combinations with Repetition

13.77 (a) \( \frac{10!}{3!3!3!} \cdot \frac{10!}{3!3!3!} \).

(b) \( \frac{10!}{3!3!3!} \cdot \frac{10!}{3!3!3!} \).

(c) \( 2 \cdot \frac{12!}{3!3!3!} + 2 \cdot \frac{12!}{3!3!3!} + 3 \cdot \frac{12!}{3!3!3!} = \frac{13!}{3!3!3!} \).

13.79 \( 1 + \frac{6!}{3!3!} + \frac{7!}{5!3!} = 1 + 6 + 21 + 56 = 84. \)

13.81 Using the symbol \( \ast \) to represent 1, we determine the number of ways to distribute \( s = m \) symbols \( \ast \) and \( n-1 \) vertical separator lines | for the \( n \) variables \( x_1, x_2, \ldots, x_n \). Each such sequence of symbols \( \ast \) and separator lines \( | \) represents a solution of this equation. By Theorem 13.40, the number of ways to do this is \( \binom{m+n-1}{m} \).

13.83 The number of ways to place three gold coins in the boxes is \( \binom{13+4-1}{3} = \binom{13}{3} = 20 \), while the number of ways to place ten silver coins in the boxes is \( \binom{10+4-1}{10} = \binom{13}{10} = 286 \). By the Multiplication Principle, the number of ways to place make both placements is \( (20)(286) = 5720 \).

13.85 (a) \( (x+y+z)^2 = x^2 + y^2 + z^2 + 2xy + 2xz + 2yz \).

(b) \( (x+y+z)^3 = x^3 + y^3 + z^3 + 3x^2y + 3x^2z + 3xy^2 + 3xz^2 + 3yz^2 + 6xyz \).

13.87 (a) The number \( |S| \) of elements in \( S \) is the number of triples \( (i, j, k) \) of nonnegative integers such that \( i + j + k = n \). Applying Theorem 13.40 with \( s = n \) and \( t = 3 \), we see that \( |S| = \binom{i+j+k-1}{s-1} = \binom{n+2}{3} = \frac{(n+2)(n+1)}{2} \).
(b) Since \((x + y + z)^n\) is the product of \(n\) trinomials, each of which is \(x + y + z\), the term involving \(x^iy^jz^k\) is obtained by selecting \(x\) in \(i\) of the \(n\) trinomials, \(y\) in \(j\) of the remaining \(n - i\) trinomials and \(z\) in \(k\) of the remaining \(n - i - j\) trinomials. Thus, the number of ways of doing this is
\[
\binom{n}{i} \binom{n-i}{j} \binom{n-i-j}{k} = \frac{n!}{i!(n-i)!} \cdot \frac{(n-i)!}{j!(n-i-j)!} \cdot \frac{(n-i-j)!}{k!}.
\]

[Notice that this is the number of permutations of \(n\) objects, \(i\) of which are \(x\), \(j\) of which are \(y\) and \(k\) of which are \(z\). By Theorem 13.36, this number is \(\binom{n}{i,j,k}\).]

(c) The number of terms in the expansion of \((x + y + z)^n\) is the number of distinct expressions of the type \(x^iy^jz^k\) with \(i + j + k = n\). This is \(|S|\), which is \(\binom{n+2}{2}\).

\[
(x + y + z)^n = \sum_{(i,j,k)\in S} \binom{n}{i,j,k} x^i y^j z^k.
\]

(e) Letting \(x = y = z = 1\), we have \(\sum_{(i,j,k)\in S} \binom{n}{i,j,k} = 3^n\).

13.89 The number of integer solutions of this equation satisfies the given conditions equals the number of nonnegative integer solutions of the equation \(x_1 + x_2 + \cdots + x_n = m = \binom{n+1}{n} = \binom{n}{n-1}\), which is \(\frac{n+1}{2}\).

13.91 (a) 1, 3, 4; 1, 5; 1, 6; 2, 4; 2, 5; 2, 6; 3, 5; 3, 6; 4, 6 (ten pairs in all).

(b) Once six integers have been selected to remove from this sequence, a new sequence of eight integers with six gaps is produced. There are nine possible locations for these six gaps, namely between two of the remaining eight integers or at each end of this new sequence. Since selecting six integers from the original sequence is equivalent to choosing six of the nine locations for gaps, this can be done in \(\binom{9}{6}\) ways.

EXERCISES FOR CHAPTER 14

Section 14.1: Limits of Sequences

14.1 Since \(\cos n\pi = -1\) when \(n\) is odd and \(\cos n\pi = 1\) when \(n\) is even, the terms of the sequence \((-1)^n\) are exactly the same as \(\{\cos n\pi\}\).

14.3 Proof Let \(\epsilon > 0\) be given. Choose \(N = \lceil \frac{1}{2\epsilon} \rceil\) and let \(n > N\). Thus, \(n > \frac{1}{2\epsilon}\) and so \(\left|\frac{1}{2\pi} - 0\right| = \frac{1}{2\pi} < \epsilon\).

14.5 Proof Let \(\epsilon > 0\) be given. Choose \(N = \max(1, \lceil \log_2 (\frac{1}{\epsilon}) \rceil)\) and let \(n > N\). Thus, \(n > \log_2 (\frac{1}{\epsilon})\) and so \(2^n > 1/\epsilon\) and \(1/2^n < \epsilon\). Therefore, \(|(1 + \frac{1}{2^n}) - 1| = \frac{1}{2^n} < \epsilon\).

14.7 There exists a real number \(\epsilon > 0\) such that for each positive integer \(N\), there exists an integer \(n > N\) such that \(|a_n - L| \geq \epsilon\).

For each real number \(L\), there exists \(\epsilon > 0\) such that for each positive integer \(N\), there exists \(n > N\) such that \(|a_n - L| \geq \epsilon\).

Let \(\epsilon \in \mathbb{R}^+, \forall N \in \mathbb{N}, \exists n \in \mathbb{N}, n > N, P(L, \epsilon, n)\).

14.9 Proof Let \(M\) be a positive number. Choose \(N = \lceil \sqrt{M} \rceil\) and let \(n\) be any integer such that \(n > N\). Hence, \(n > \sqrt{M}\) and so \(n^2 > M\). Thus, \(\frac{n^2 + 2n}{2n^2} = \frac{n^2}{2n^2} = \frac{1}{2} > n^3 > M\).

14.11 Proof Let \(\epsilon > 0\) be given. Since \(\lim_{n \to \infty} s_n = L\), there is a positive integer \(N\) such that \(|s_n - L| < \epsilon\) for each integer \(n > N\). Since \(n^2 \geq n\) for each \(n \in \mathbb{N}\), it follows that \(|s_n^2 - L| < \epsilon\) for all \(n^2 > N\).

Section 14.2: Infinite Series

14.13 Let \(s_n = \sum_{k=1}^{n} \frac{1}{k}\) for each integer \(n \geq 1\).

(a) \(s_1 = \frac{1}{1}, s_2 = \frac{1}{2} + \frac{1}{2} = \frac{1}{4}, s_3 = \frac{1}{2} + \frac{1}{2} + \frac{1}{2} = \frac{3}{4}, s_4 = \frac{1}{2} + \frac{1}{2} + \frac{1}{2} + \frac{1}{2} = \frac{5}{4}\).

Conjecture \(s_n = 1 - \frac{1}{n}\) for all \(n \in \mathbb{N}\).
476 Answers to Odd-Numbered Section Exercises

(b) **Proof**  We proceed by induction. Since \( s_1 = \frac{1}{2} = 1 - \frac{1}{2^1} \), the formula \( s_n \) holds for \( n = 1 \). Thus, the statement is true for \( n = 1 \). Assume that \( s_k = 1 - \frac{1}{2^k} \) for a positive integer \( k \). We show that \( s_{k+1} = 1 - \frac{1}{2^{k+1}} \).

Observe that

\[
\sum_{i=1}^{k+1} \frac{1}{2^i} = \left( \sum_{i=1}^{k} \frac{1}{2^i} \right) + \frac{1}{2^{k+1}} = 1 - \frac{1}{2^k} + \frac{1}{2^{k+1}} = 1 - \frac{2 - 1}{2^{k+1}} = 1 - \frac{1}{2^{k+1}}.
\]

By the Principle of Mathematical Induction, \( s_n = 1 - \frac{1}{2^n} \) for all \( n \in \mathbb{N} \).

(c) The proof that \( \lim_{n \to \infty} (1 - \frac{1}{2^n}) = 1 \) is similar to the one in Exercise 14.5.

14.15 **Proof**  Let \( M \) be a positive integer. By Result 14.12, there exists a positive integer \( N \) such that if \( n > N \), then

\[ 1 + \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n} > M. \]

Since \( n^2 + 3n \geq n^2 + 2n + 1 \) for every positive integer \( n \), it follows that \( \frac{n}{n+1} \geq \frac{1}{2} \).

Hence,

\[
\frac{4}{2^2} + \frac{5}{3^2} + \cdots + \frac{n+3}{(n+1)^2} \geq \frac{1}{2} + \frac{1}{3} + \cdots + \frac{1}{n} > M
\]

and so \( \sum_{k=1}^{\infty} \frac{k+1}{k+1} \) diverges to infinity.

14.17 (a) Since \( s_n = \frac{3n}{4n^2 + 2} \), it follows that \( s_{n-1} = \frac{3n-3}{4n^2 - 2} \) and so

\[
a_n = s_n - s_{n-1} = \frac{3n}{4n^2 + 2} - \frac{3n-3}{4n^2 - 2} = \frac{6}{16n^2 - 4} = \frac{3}{8n^2 - 2}.
\]

Therefore, the series is \( \sum_{k=1}^{\infty} \frac{1}{8k^2 - 2} \).

(b) The sum \( s \) of the series is \( s = \lim_{n \to \infty} \frac{3n}{4n^2 + 2} \). We claim that \( \lim_{n \to \infty} \frac{3n}{4n^2 + 2} = \frac{1}{2} \).

**Proof**  Let \( \epsilon > 0 \) be given. Let \( N = \max\{1, \lceil \frac{3}{8\epsilon} - \frac{1}{2} \rceil \} \) and let \( n > N \). Then \( n > \frac{3}{8\epsilon} - \frac{1}{2} \) and so \( \frac{3}{8n^2} < \epsilon \).

Thus,

\[
\left| \frac{3n}{4n^2 + 2} - \frac{3}{4} \right| = \left| \frac{6}{16n + 8} \right| = \frac{3}{8n + 4} < \epsilon,
\]

completing the proof.

Section 14.3: Limits of Functions

14.19 **Proof**  Let \( \epsilon > 0 \) be given. Choose \( \delta = \epsilon / 3 \). Let \( x \in \mathbb{R} \) such that \( 0 < |x + 1| < \delta = \epsilon / 3 \). Then

\[
|(3x - 5) - (-8)| = |3x + 3| = 3|x + 1| < 3\delta = 3(\epsilon / 3) = \epsilon,
\]

as desired.

14.21 **Proof**  Let \( \epsilon > 0 \) be given and choose \( \delta = \min(1, \epsilon / 19) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 2| < \delta = \min(1, \epsilon / 19) \).

Since \( |x - 2| < 1 \), it follows that \( -1 < x - 2 < 1 \) and so \( 1 < x < 3 \). Thus, \( |x^2 + 2x + 4| < 19 \). Because \( |x - 2| \leq \epsilon / 19 \), it follows that \( |x^2 - 8| = |x - 2||x^2 + 2x + 4| < |x - 2| \cdot 19 < (\epsilon / 19) \cdot 19 = \epsilon \).

14.23 **Proof**  Let \( \epsilon > 0 \) be given. Choose \( \delta = \min(1, 33\epsilon) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 3| < \delta \).

Since \( |x - 3| < \delta \leq 1 \), it follows that \( 2 < x < 4 \). Thus, \( 11 < 4x + 3 < 19 \) and so \( |4x + 3| > 11 \). Hence, \( \frac{1}{|4x+3|} < \frac{1}{17} \).

Therefore,

\[
\left| \frac{3x + 1}{4x + 3} - \frac{2}{3} \right| = \left| \frac{x - 3}{12x + 9} \right| = \frac{|x - 3|}{3|4x + 3|} < \frac{|x - 3|}{3 \cdot 11} < \frac{\delta}{33} \leq \frac{1}{33} (33\epsilon) = \epsilon,
\]

as desired.

14.25 **Proof**  Assume, to the contrary, that \( \lim_{x \to 0} \frac{1}{x^2} \) exists. Then there exists a real number \( L \) such that \( \lim_{x \to 0} \frac{1}{x^2} = L \).

Let \( \epsilon = 1 \). There exists \( \delta > 0 \) such that if \( 0 < |x| < \delta \), then \( \frac{1}{x^2} < L < \epsilon = 1 \). Let \( n \) be an integer such that
n > \left\lfloor 1/\delta^2 \right\rfloor. So, n > 1/\delta^2 and \sqrt{n} > 1/\delta. Let x = 1/\sqrt{n} < \delta. Then
\[
\left| 1/x^2 - L \right| = \left| n - L \right| = \left| L - n \right| < 1
\]
and so -1 < L - n < 1. Thus, n - 1 < L < n + 1. Now, let y = \frac{1}{\sqrt{n+2}} < x < \delta. Then
\[
\left| 1/y^2 - L \right| = \left| L - (n + 2) \right| < 1.
\]
Hence, n + 1 < L < n + 3. Therefore, n + 1 < L < n + 1, which is a contradiction.

14.27 (a) Proof Let \epsilon > 0 be given. Since g is bounded, there exists a positive real number B such that |g(x)| < B for each x \in \mathbb{R}. Then \epsilon/B > 0. Since \lim_{x \to 0} f(x) = 0, there exists \delta > 0 such that if 0 < |x - a| < \delta, then |f(x) - 0| < \frac{\epsilon}{B} and so |f(x)| < \epsilon/B. Therefore, |(f(x)g(x) - 0)| = |f(x)||g(x)| < \frac{\epsilon}{B} \cdot B = \epsilon.
(b) Since \lim_{x \to 0} x^2 = 0 and \left| \sin \left( \frac{1}{x^2} \right) \right| \leq 1 for all x \in \mathbb{R} \setminus \{0\}, it follows from (a) that
\[
\lim_{x \to 0} x^2 \sin \left( \frac{1}{x^2} \right) = 0.
\]

14.29 (a) Proof Let \epsilon > 0 be given. Since \lim_{x \to 0} f(x) = L, there exists \delta > 0 such that if 0 < |x - 0| < \delta, then |f(x) - L| < \epsilon. Let y = x - c. Because \lim_{x \to 0} f(y) = L, given \epsilon > 0, there exists \delta > 0 such that if 0 < |y - 0| < \delta, then |f(y) - L| < \epsilon. Thus, if 0 < |x - c| < \delta, then |f(x - c) - L| < \epsilon. Therefore, \lim_{x \to c} f(x - c) = L.
(b) Proof By assumption, f(x) = f(x - c + c) = f(x - c) + f(c). Since \lim_{x \to 0} f(x) = L, it follows by (a) that \lim_{x \to c} f(x - c) = \lim_{x \to 0} f(x - c) = L. Thus,
\[
\lim_{x \to c} f(x) = \lim_{x \to c} [f(x - c) + f(c)] = \lim_{x \to c} f(x - c) + \lim_{x \to c} f(c) = L + f(c)
\]
and so \lim_{x \to c} f(x) exists for each x \in \mathbb{R}.

Section 14.4: Fundamental Properties of Limits of Functions

14.31 (a) \lim_{x \to 1}(x^3 - 2x^2 - 5x + 8) = 1^3 - 2(1)^2 - 5 \cdot 1 + 8 = 2.
(b) \lim_{x \to 1}(4x + 7)(3x^2 - 2) = (4 \cdot 1 + 7)(3 \cdot 1^2 - 2) = 11 \cdot 1 = 11.
(c) \lim_{x \to 2} \frac{x^2 - 1}{x^2 - 1} = \frac{2^2 - 1}{2^2 - 1} = \frac{3}{3}.

14.33 Proof First, by Theorem 14.28, \lim_{x \to a} c_0 = c_0. For 1 \leq k \leq n, it follows by Theorems 14.25, 14.28 and 14.30 that \lim_{x \to a} (c_k x^k) = (\lim_{x \to a} c_k)(\lim_{x \to a} x^k) = c_k a^k. By Exercise 14.32, \lim_{x \to a} (c_n x^n + c_{n-1} x^{n-1} + \cdots + c_1 x + c_0) = c_n a^n + c_{n-1} a^{n-1} + \cdots + c_1 a + c_0 = p(a).

Section 14.5: Continuity

14.35 Observe that f is not defined at x = 2 and
\[
\lim_{x \to 2} \frac{x^2 - 4}{x - 2} = 1.
\]
(Use an argument similar to that in Result 14.15.) Thus, if we define f(2) = 1, then \lim_{x \to 2} f(x) = 1 = f(2) and so f is continuous at 2.

14.37 Proof Let a be a real number that is not an integer. Then n < a < n + 1 for some n \in \mathbb{Z} and f(a) = \lceil a \rceil = n + 1. We show that \lim_{x \to a} f(x) = f(a) = n + 1. Let \epsilon > 0 be given and choose
\[
\delta = \min(1 - a, n + 1 - a).
\]
Let x \in \mathbb{R} such that 0 < |x - a| < \delta. Thus, n < a - \delta < x < a + \delta \leq n + 1 and so f(x) = \lceil x \rceil = n + 1. Therefore,
\[
|f(x) - f(a)| = |(n + 1) - (n + 1)| = 0 < \epsilon,
\]
completing the proof.
478 Answers to Odd-Numbered Section Exercises

14.39 We show that \( \lim_{x \to 10} \sqrt{x - 1} = f(10) = 3. \) **Proof** Let \( \varepsilon > 0 \) be given and choose \( \delta = \min(1, 5\varepsilon) \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 10| < \delta \). Since \( |x - 10| < 1 \), it follows that \( 9 < x < 11 \) and so \( \sqrt{x - 1} > 3 > 1/5 \). Therefore, \( 1/(\sqrt{x - 1} + 3) < 1/5 \). Hence,

\[
|\sqrt{x - 1} - 3| = \left| \frac{\sqrt{x - 1} - 3(\sqrt{x - 1} + 3)}{\sqrt{x - 1} + 3} \right| = \frac{|x - 10|}{\sqrt{x - 1} + 3} < \frac{1}{5} (5\varepsilon) = \varepsilon,
\]

completing the proof.

**Section 14.6: Differentiability**

14.41 \( f'(3) = 6. \) **Proof** Let \( \varepsilon > 0 \) be given and choose \( \delta = \varepsilon \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - 3| < \delta = \varepsilon \). Then

\[
\left| \frac{f(x) - f(3)}{x - 3} - 6 \right| = \left| \frac{x^2 - 9}{x - 3} - 6 \right| = \left| \frac{(x - 3)(x + 3) - 6}{x - 3} \right| = |x + 3| - 6 = |x - 3| < \varepsilon.
\]

Thus, \( f'(3) = 6. \) **Proof** Let \( \varepsilon > 0 \) be given and choose \( \delta = \min \left\{ \frac{\varepsilon}{1 + 3\varepsilon}, 1 \right\} \). Let \( x \in \mathbb{R} \) such that \( 0 < |x - a| < \delta \). Then

\[
|x + 2a| = |(x - a) + 3a| \leq |x - a| + 3|a| < 1 + 3a.
\]

Observe that

\[
\left| \frac{f(x) - f(a)}{x - a} - 3a^2 \right| = \left| \frac{(x - a)(x^2 + ax + a^2)}{x - a} - 3a^2 \right| = |x^2 + ax + a^2 - 3a^2| \leq \left( \frac{\varepsilon}{1 + 3a} \right) (1 + 3a) = \varepsilon.
\]

Thus, \( f'(a) = 3a^2. \)

**EXERCISES FOR CHAPTER 15**

**Section 15.1: Binary Operations**

15.1 (a) \( x \ast (y \ast z) = x \ast y = x \ast z = z \ast y = z. \) So, \( x \ast (y \ast z) = (x \ast y) \ast z. \)

(b) \( x \ast (x \ast x) = x \ast x = z \ast z = x = y. \)

(c) \( y \ast (y \ast y) = y \ast x = y \ast y = z. \)

(d) The binary operation \( \ast \) is neither associative nor commutative.

15.3 (a) Let \( A_1, A_2 \in T \). Then \( A_1 = \begin{bmatrix} a_1 & b_1 \\ b_1 & a_1 \end{bmatrix} \) and \( A_2 = \begin{bmatrix} a_2 & b_2 \\ b_2 & a_2 \end{bmatrix} \) for some \( a_1, b_1, a_2, b_2 \in \mathbb{R}. \) Then

\[
A_1 + A_2 = \begin{bmatrix} a_1 + a_2 & (b_1 + b_2) \\ b_1 + b_2 & a_1 + a_2 \end{bmatrix}.
\]

Since \( A_1 + A_2 \in T \), it follows that \( T \) is closed under matrix addition.

(b) Since \( A_1 A_2 = \begin{bmatrix} a_1 & b_1 \\ b_1 & a_1 \end{bmatrix} \begin{bmatrix} a_2 & b_2 \\ b_2 & a_2 \end{bmatrix} = \begin{bmatrix} a_1 a_2 & b_1 b_2 - a_1 b_2 + b_1 a_2 \\ b_1 a_2 + b_2 a_1 & a_1 a_2 - b_1 b_2 \end{bmatrix} \in T \), it follows that \( T \) is closed under matrix multiplication.

15.5 **Proof** Let \( a, b \in T. \) Thus, \( a \ast a = a \) and \( b \ast b = b. \) Hence,

\[
(a \ast b) \ast (a \ast b) = (a \ast b) \ast (b \ast a) = a \ast (b \ast (b \ast a)) = a \ast ((b \ast b) \ast a) = a \ast (b \ast a) = a \ast (a \ast b) = (a \ast a) \ast b = a \ast b,
\]

as desired.
15.7 All four properties G1 – G4 are satisfied. In this case, \([-1] = [n - 1]\) is an identity element and \([-a - 2]\) is an inverse for \([a]\).

Section 15.2: Groups

\[
\begin{array}{c|cccc}
* & a & b & c & d \\
\hline
a & d & c & b & a \\
b & c & d & a & b \\
c & b & a & d & c \\
d & a & b & c & d \\
\end{array}
\]

15.9 See the table.

15.11 (a) First, observe that \([1][b] = [b]\) for each \([b] \in \mathbb{Z}_6^\ast\) and that \([5][-b] = [b]\) for each \([b] \in \mathbb{Z}_6^\ast\). There is no \([x] \in \mathbb{Z}_6^\ast\) such that \([2][x] = [1]\) or that \([3][x] = [1]\) or that \([4][x] = [1]\).

(b) Because of Theorem 15.5, the answer to (a) is not surprising.

15.13 \textbf{Proof} First, we show that if \(g\) is any element of \(G\) such that \(g * g = g\), then \(g = e\). Suppose then that \(g * g = g\). By (ii), there exists \(g' \in G\) such that \(g * g' = e\). Thus,

\[
e = g * g' = (g * g) * g' = g * (g * g') = g * e = g
\]

by (i). We now show that \(g' * g = e\). Since

\[
(g' * g) * (g' * g) = (g' * g) * g = g * (g * g')
\]

it follows that \(g' * g = e\).

Next, we show that \(e * g = g\) for every \(g \in G\). Let \(g \in G\). Then, as we just showed, there is \(g' \in G\) such that \(g' * g = e\). Thus, \(e * g = (g * g') * g = g * (g' * g) = g * e = g\) by (i).

Section 15.3: Permutation Groups

15.15 Let \(a, b, c \in A\). Let \(\alpha, \beta \in S_A\) such that \(\alpha(a) = b, \alpha(b) = a\) and \(\alpha(x) = x\) for \(x \neq a, b\); while \(\beta(b) = c, \beta(c) = b\) and \(\beta(x) = x\) for \(x \neq b, c\). Then \((\alpha \circ \beta)(b) = \alpha(\beta(b)) = \alpha(c) = c\); while \((\beta \circ \alpha)(b) = \beta(\alpha(b)) = \beta(a) = a\). Thus, \(\alpha \circ \beta \neq \beta \circ \alpha\).

15.17 \(x^4 = \alpha_1\) for all \(x \in \{\alpha_1, \alpha_2, \alpha_3, \alpha_4\}\). \(x^6 = \alpha_1\) for all \(x \in \{\alpha_1, \alpha_2, \alpha_3\}\).

15.19 Consider the operation table shown below. Thus, \(\circ\) is a binary operation on \(G\). Since composition of permutations on \(A\) is associative, property G1 is satisfied. In addition, \(\beta_1\) is an identity and the elements \(\beta_1, \beta_2, \beta_3, \beta_4, \beta_5, \beta_6\) are inverses of \(\beta_1, \beta_3, \beta_2, \beta_4, \beta_6, \beta_5\), respectively. Therefore, properties G2 and G3 are satisfied and so \((G, \circ)\) is a group.

\[
\begin{array}{c|cccccc}
\circ & \beta_1 & \beta_2 & \beta_3 & \beta_4 & \beta_5 & \beta_6 \\
\hline
\beta_1 & \beta_1 & \beta_2 & \beta_3 & \beta_4 & \beta_5 & \beta_6 \\
\beta_2 & \beta_2 & \beta_3 & \beta_4 & \beta_5 & \beta_6 & \beta_1 \\
\beta_3 & \beta_3 & \beta_1 & \beta_5 & \beta_6 & \beta_2 & \beta_4 \\
\beta_4 & \beta_4 & \beta_6 & \beta_1 & \beta_2 & \beta_5 & \beta_3 \\
\beta_5 & \beta_5 & \beta_6 & \beta_2 & \beta_1 & \beta_3 & \beta_4 \\
\beta_6 & \beta_6 & \beta_1 & \beta_4 & \beta_3 & \beta_2 & \beta_5 \\
\end{array}
\]

Section 15.4: Fundamental Properties of Groups

15.21 \textbf{Proof} Assume that \(b * a = c * a\). Let \(s\) be an inverse for \(a\). Then \((b * a) * s = (c * a) * s\). Thus,

\[
b = b * e = b * (a * s) = (b * a) * s = (c * a) * s = c * (a * s) = c * e = e
\]

and so \(b = c\).

15.23 (a) \(x = a^{-1} * c * b^{-1}\). (If \(x_1\) and \(x_2\) are two solutions, then \(a * x_1 * b = a * x_2 * b = c\). An application of the Left and Right Cancellation Laws yields \(x_1 = x_2\).)

(b) \(x = b^{-1} * a^{-1} * c\). (Verifying the uniqueness is similar to (a).)
480 Answers to Odd-Numbered Section Exercises

15.25 Proof Assume that $G$ is abelian. Let $a, b \in G$. By Theorem 15.11, $(ab)^{-1} = b^{-1}a^{-1}$. Since $G$ is abelian, $b^{-1}a^{-1} = a^{-1}b^{-1}$. For the converse, assume that $G$ is a group such that $(ab)^{-1} = a^{-1}b^{-1}$ for every pair $a, b$ of elements of $G$. We show that $G$ is abelian. Let $x, y \in G$. Then $(xy)^{-1} = x^{-1}y^{-1}$. Since $x^{-1}y^{-1} = (xy)^{-1}$, it follows that $(xy)^{-1} = (xy)^{-1}$. Since every element of a group has a unique inverse, $xy = yx$. Thus, $G$ is abelian.

15.27 Claim: $e'$ is the identity of $G$. Proof Since $e'b = b$ and $eb = b$, it follows that $e'b = eb$. Applying the Right Cancellation Law in Theorem 15.7, we have $e' = e$.

15.29 Proof Since $G$ has even order, $G - \{e\}$ has an odd number of elements. Consider those elements $g \in G$ for which $g \neq g^{-1}$ and let $S_g = \{g, g^{-1}\}$. Hence, $S_g = S_{g^{-1}}$. If we take the union of all such sets $S_g$ for which $g \neq g^{-1}$, then $\cup S_g \subseteq G - \{e\}$. Hence, there exists an element $h \in G - \{e\}$ such that $h \notin \cup S_g$ and so $h = h^{-1}$. Thus, $h^2 = e$.

Section 15.5: Subgroups

15.31 Proof Let $a, b \in n\mathbb{Z}$. Then $a = nk$ and $b = nl$ for $k, l \in \mathbb{Z}$. Since $a + b = nk + nl = n(k + l)$ and $k + l \in \mathbb{Z}$, it follows that $a + b \in n\mathbb{Z}$. The identity of $n\mathbb{Z}$ is $0 = 0n$. For $a = nk$, the integer $-a = (-k)n$ is the inverse of $a$ since $a + (-a) = kn + (-k)n = 0$. Since $-k \in \mathbb{Z}$, $-a \in n\mathbb{Z}$. By the Subgroup Test, $(n\mathbb{Z}, +)$ is a subgroup of $(\mathbb{Z}, +)$.

15.33 (a) The statement is true. Proof Since $H$ and $K$ are subgroups of $G$, it follows that $e \in H$ and $e \in K$. So, $e \in H \cap K$ and $H \cap K \neq \emptyset$. Let $a, b \in H \cap K$. Then, $a, b \in H$ and $a, b \in K$. Since $H$ and $K$ are subgroups of $G$, it follows that $ab \in H$ and $ab \in K$. So, $ab \in H \cap K$. It remains to show that $a^{-1} \in H \cap K$. Since $a \in H, a \in K$, and $H$ and $K$ are subgroups of $G$, it follows that $a^{-1} \in H$ and $a^{-1} \in K$. So, $a^{-1} \in H \cap K$. By the Subgroup Test, $H \cap K$ is a subgroup of $G$.

(b) The statement is false. For example, $H = \{[0], [3]\}$ and $K = \{[0], [2], [4]\}$ are subgroups of $(\mathbb{Z}_6, +)$, but $H \cup K$ is not a subgroup of $(\mathbb{Z}_6, +)$.

15.35 Proof Since $\sqrt{3} \in H$, it follows that $H \neq \emptyset$. First, we show that $H$ is closed under multiplication. Let $r = a + b\sqrt{3}$ and $s = c + d\sqrt{3}$ be elements of $H$, where at least one of $a$ and $b$ is nonzero and at least one of $c$ and $d$ is nonzero. Therefore, $r \neq 0$ and $s \neq 0$. Hence, $rs \neq 0$ and

$$rs = (ac + bd) + (ad + bc)\sqrt{3}.$$ 

Thus, at least one of $ac + bd$ and $ad + bc$ is nonzero. Since $ac + bd, ad + bc \in \mathbb{Q}$, it follows that $rs \in H$, and so $H$ is closed under multiplication.

Next, we show that every element of $H$ has an inverse in $H$. Let $r = a + b\sqrt{3} \in H$, where at least one of $a$ and $b$ is nonzero. Then

$$\frac{1}{r} = \frac{1}{a + b\sqrt{3}} = \frac{1}{a + b\sqrt{3}} \cdot \frac{a - b\sqrt{3}}{a - b\sqrt{3}} = \frac{a - b\sqrt{3}}{a^2 - 3b^2} = \frac{a}{a^2 - 3b^2} - \frac{b}{3b^2 - a^2} \sqrt{3}.$$ 

Observe that $3b^2 - a^2 \neq 0$; for if $3b^2 - a^2 = 0$, then $a/b = \pm\sqrt{3}$, which is impossible since $a/b \in \mathbb{Q}$ and $\sqrt{3}$ is irrational. Hence, $1/r \in H$.

By the Subgroup Test, $H$ is a subgroup.

15.37 Proof Let $A_1, A_2 \in H$. Then each of det($A_1$) and det($A_2$) is 1 or $-1$. Since the determinant of $A_1A_2$ is the product of the determinants of $A_1$ and $A_2$, it follows that det($A_1A_2$) is 1 or $-1$. Thus, $A_1A_2 \in H$. Next, let $A \in H$. So, det($A$) is 1 or $-1$. Since det($A$) $\neq 0$, it follows that $A^{-1}$ exists. We show that $A^{-1} \in H$. Since $AA^{-1} = I$ (the identity in $M_2(\mathbb{R})$) and det($I$) = 1, it follows that det($A^{-1}$) det($A$) = 1. Because det($A$) is 1 or $-1$, so is det($A^{-1}$). Thus, $A^{-1} \in H$. By the Subgroup Test, $(H, \cdot)$ is a subgroup of $(M_2(\mathbb{R}), \cdot)$.

15.39 Proof For the identity $e$ of $G$, it follows that $e^2 = e \in H$ and so $H \neq \emptyset$. Let $a, b \in H$. Then $a^2 = b^2 = e$. Then $(ab)^2 = a^2b^2 = e \cdot e = e$ and so $ab \in H$. Therefore, $H$ is closed under multiplication. Let $a \in H$. Then $a^2 = e$. Thus, $(a^2)^{-1} = e$. However, $(a^2)^{-1} = (a^{-1})^2 = e$ and so $a^{-1} \in H$. By the Subgroup Test, $H$ is a subgroup of $G$. 

Exercises for Chapter 15

15.41 The statement is false. Since $22 \nmid 372$, no group of order 372 contains a subgroup of order 22.

15.43 (a) **Proof** Since $H$ is closed under $*$, it suffices to show $g^{-1} \in H$ for each $g \in H$. Let $H = \{g_1, g_2, \ldots, g_k\}$ and let $g \in H$. We claim that $g * g_1, g * g_2, \ldots, g * g_k$ are $k$ distinct elements in $H$. Suppose this is not the case. Then $g * g_i = g * g_j$ for distinct elements $g_i, g_j \in H$. By the Left Cancellation Law, $g_i = g_j$, which is impossible. Thus, as claimed, $g * g_1, g * g_2, \ldots, g * g_k$ are $k$ distinct elements in $H$ and so

$$H = \{g * g_1, g * g_2, \ldots, g * g_k\}.$$ 

Since $g \in H$, it follows that $g = g * g_i$ for some integer $i$ with $1 \leq i \leq k$. Hence, $g = g * g_i = g * e$ for the identity $e$ of $G$. By the Left Cancellation Law, $g_i = e$ and so $e \in H$. Therefore, $g * g_j = e$ for some integer $j$ with $1 \leq j \leq k$ and so $g_j = g^{-1}$, implying that $g^{-1} \in H$. By the Subgroup Test, $H$ is a subgroup of $G$. ■

(b) The set $N$ is a subset of the infinite group $(\mathbb{Z}, +)$. Note that $N$ is closed under $+$, but $N$ is not a subgroup of $(\mathbb{Z}, +)$ by Exercise 15.32(a).

15.45 Since there are six distinct left cosets of $H$ in $G$, one of which is $H$ and every two left cosets have the same number of elements, it follows that the order of $H$ is $48/6 = 8$.

15.47 The statement is false. Suppose that $g^2 \in gH$. Then $g^2 = gh$ for some $h \in H$. Thus, $g = h$, contradicting the fact that $gH \neq H$.

**Section 15.6: Isomorphic Groups**

15.49 (a) Since 1 is not the image of any integer under $\phi$, the function $\phi$ is not onto and so $\phi$ is not an isomorphism.

(b) Since $\phi(0) = 1$, the image of the identity 0 in $(\mathbb{Z}, +)$ is not the identity in $(\mathbb{Z}, +)$. By Theorem 15.18(a), $\phi$ is not an isomorphism.

(c) The function $\phi$ is an isomorphism.

**Proof** First, we show that $\phi$ is one-to-one. Suppose that $\phi(a) = \phi(b)$, where $a, b \in \mathbb{R}$. Then $2^a = 2^b$. Thus, $a = \log_2 2^a = \log_2 2^b = b$ and so $\phi$ is one-to-one. Next, we show that $\phi$ is onto. Let $r \in \mathbb{R}^+$. Then $\log_2 r \in \mathbb{R}$. Hence, $\phi(\log_2 r) = 2^{\log_2 r} = r$ and so $\phi$ is onto. Finally, we show that $\phi$ is operation-preserving. For $a, b \in \mathbb{R}$,

$$\phi(a + b) = 2^{a+b} = 2^a \cdot 2^b = \phi(a) \cdot \phi(b).$$

Therefore, $\phi$ is an isomorphism. ■

(d) Let $A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$ and $B = \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}$. Then $\phi(A) = \phi(B) = 1$, but $A \neq B$. Thus, $\phi$ is not one-to-one and so $\phi$ is not an isomorphism.

15.51 **Proof** Assume that $\phi : G \rightarrow H$ is an isomorphism. Since $\phi$ is a bijection, $\phi^{-1}$ is a bijection by Theorem 10.15. It remains to show that $\phi^{-1}$ is operation-preserving. Let $h_1, h_2 \in H$. Then there exist $g_1, g_2 \in G$ such that $\phi(g_1) = h_1$ and $\phi(g_2) = h_2$. Thus, $\phi^{-1}(h_1) = g_1$ and $\phi^{-1}(h_2) = g_2$. Furthermore, $\phi(g_1 * g_2) = \phi(g_1) \circ \phi(g_2) = h_1 \circ h_2$. Hence, $\phi^{-1}(h_1 \circ h_2) = g_1 * g_2 = \phi^{-1}(h_1) \ast \phi^{-1}(h_2)$. Thus, $\phi^{-1}$ is operation-preserving and so $\phi^{-1}$ is an isomorphism. ■

15.53 (a) **Proof** Let $a, b \in G$. Since $a \circ b = b \ast a \in G$, it follows that $\circ$ is a binary operation on $G$. Let $a, b, c \in G$. Then $a \circ (b \circ c) = a \circ (b * a) = (a * b) * a = (b \circ c) * a = a \circ (b \circ c)$. Thus, $\circ$ is an associative operation. Let $e$ be the identity of $(G, \ast)$. Then

$$a \circ e = e \ast a = a = a \ast e = e \circ a$$

and so $e$ is the identity of $(G, \circ)$. Let $g \in (G, \circ)$ and let $g^{-1}$ be the inverse of $g$ in $(G, \ast)$. Then

$$g \circ g^{-1} = g^{-1} * g = e = g \ast g^{-1} = g^{-1} \circ g.$$ 

Thus, $g^{-1}$ is the inverse of $g$ in $(G, \circ)$. Therefore, $(G, \circ)$ is a group.

(b) **Proof** Consider the function $\phi : (G, \ast) \rightarrow (G, \circ)$ defined by $\phi(g) = g^{-1}$ for each $g \in G$. We show that $\phi$ is an isomorphism. First, we show that $\phi$ is bijective. Let $\phi(g_1) = \phi(g_2)$, where $g_1, g_2 \in (G, \ast)$. Then $g_1^{-1} = g_2^{-1}$. Since $(g_1^{-1})^{-1} = (g_2^{-1})^{-1}$ in $(G, \circ)$, it follows that $g_1 = g_2$ in $(G, \ast)$. Thus, $\phi$ is one-to-one.
Let \( h \in (G, \circ) \). Then \( \phi(h^{-1}) = (h^{-1})^{-1} = h \) and so \( \phi \) is onto. It remains to show \( \phi \) is operation-preserving. Let \( g_1, g_2 \in (G, \ast) \). Then \( \phi(g_1 \ast g_2) = (g_1 \ast g_2)^{-1} = (g_2 \circ g_1)^{-1} = g_1^{-1} \circ g_2^{-1} = \phi(g_1) \circ \phi(g_2) \) and so \( \phi \) is operation-preserving. Therefore, \( \phi \) is an isomorphism, implying that \((G, \ast) \) and \((G, \circ) \) are isomorphic.

**Proof** Define \( \phi : Z \to Z \) by \( \phi(n) = n + 1 \) for each \( n \in Z \). Then \( \phi \) is bijective. We show that \( \phi \) is an isomorphism from \((Z, +) \to (Z, \ast)\). For \( m, n \in Z \), \( \phi(m + n) = m + n + 1 \). Since \( \phi(1) \ast \phi(n) = (m + 1) \ast (n + 1) = (m + 1) + (n + 1) - 1 = m + n + 1 \), it follows that \( \phi(m + n) = \phi(m) \ast \phi(n) \). Thus, \( \phi \) is an isomorphism.

**Proof** Let \( f, g \) be odd integers, \( f > g \). Next, let \( f_a, f_b \in F \). For \( x, y \in R^* \), \( f_a(x) = f_a(y) \) if and only if \( x^a = y^a \). Thus, \( (x^a)^b = y^b \) and \( x^m = y^m \). Hence, \( f_a \) is one-to-one. Next, we show that \( f_a \) is onto. Let \( r \in R^* \). Then \( f_a(r^a) = (r^a)^b = (r^a)^b = r \). Hence, \( f_a \) is onto. Since \( f_a \) is one-to-one and onto, it is a bijection. For \( a, b \in A \), \( f_a \circ f_b = f_a(f_b(y)) = f_a(y^a) = x^a = f_b(x) = f_b(y^b) = y^b = f_a(x) \). Thus, \( f_a \circ f_b = f_b \circ f_a \). Since \( \phi \) is an isomorphism, \( f_a \circ f_b = f_b \circ f_a \). Since \( f_a \circ f_b = f_b \circ f_a \), \( f_a \circ f_b \) is an isomorphism.
Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19

EXERCISES FOR CHAPTER 16

16.1 (a) **Proof** Let \( a, b \in k \mathbb{Z} \). Then \( a = kx \) and \( b = ky \) for some \( x, y \in \mathbb{Z} \). Note that \( a + b = kx + ky = k(x + y) \) and \( ab = (kx)(ky) = k(kxy) \). Since \( x + y, kxy \in \mathbb{Z} \), it follows that \( a + b, ab \in k \mathbb{Z} \), so the addition and multiplication defined are binary operations on \( k \mathbb{Z} \). Since \( k \mathbb{Z} \subseteq \mathbb{Z} \) and the binary operations in \( k \mathbb{Z} \) are the same as those in \( \mathbb{Z} \), properties R1, R2, R5 and R6 are automatically satisfied. Moreover, since \( 0 = k \cdot 0 \) and \( 0 \in \mathbb{Z} \), it follows that \( k \mathbb{Z} \) has an additive identity. To show that property R4 is also satisfied, let \( a \in k \mathbb{Z} \). So \( a = kx \), where \( x \in \mathbb{Z} \). Then \( -a = -(kx) = k(-x) \). Since \( -x \in \mathbb{Z} \), it follows that \( -a \in k \mathbb{Z} \). \( \blacksquare \)

16.3 (a) **Solution** We show that \((\mathbb{R}, \ast, \circ)\) is not a ring. Certainly, \( \ast \) and \( \circ \) are binary operations on \( S \). However, property R6 is not satisfied. To see this, let \( a = b = c = 0 \). Then \( a \circ (b \ast c) = 0 \circ 1 = 0 \) and \((a \circ b) \ast (a \circ c) = 0 \ast 0 = 1 \). \( \diamondsuit \)

16.7 (a) **Proof** Let \( a \in \mathbb{R} \). Then \( a^2 = a \). Thus, \((a + a)^2 = (a + a)(a + a) = a(a + a) + a(a + a) = (a^2 + a^2) + (a^2 + a^2) = (a + a) + (a + a) \). Since \((a + a)^2 = a + a \), it follows that \((a + a) + (a + a) = (a + a) + 0 \). Applying the Cancellation Law of Addition (Theorem 16.10), we obtain \( a + a = 0 \). Therefore, \(-a = a \). \( \blacksquare \)

16.9 (a) Since the zero matrix \( \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \) belongs to \( S \), it follows that \( S \neq \emptyset \). Let \( M_1, M_2 \in S \). Thus, \( M_1 = \begin{bmatrix} a_1 & 0 \\ 0 & b_1 \end{bmatrix} \) and \( M_2 = \begin{bmatrix} a_2 & 0 \\ 0 & b_2 \end{bmatrix} \), where \( a_i, b_i \in \mathbb{R} \) for \( i = 1, 2 \). Then \( M_1 - M_2 = \begin{bmatrix} a_1 - a_2 & 0 \\ 0 & b_1 - b_2 \end{bmatrix} \) and \( M_1M_2 = \begin{bmatrix} a_1a_2 & 0 \\ a_1b_2 & b_1b_2 \end{bmatrix} \) belong to \( S \). By the Subring Test, \( S \) is a subring of \( M_2(\mathbb{R}) \).

16.11 **Solution** The set \( 2G \) of even Gaussian integers is a subring of \( G \).

**Proof** Since \( 0 \in 2 \mathbb{Z} \), it follows that \( 0 = 0 + 0i \in 2 \mathbb{G} \) and so \( 2 \mathbb{G} \neq \emptyset \). Let \( x, y \in 2 \mathbb{G} \). Then \( x = a_1 + b_1i \) and \( y = a_2 + b_2i \), where \( a_i, b_i \in \mathbb{Z} \) for \( i = 1, 2 \). Then \( x - y = (a_1 - a_2) + (b_1 - b_2)i \) and \( xy = (a_1a_2 - b_1b_2) + (a_1b_2 + a_2b_1)i \). Since \( a_1 - a_2, b_1 - b_2, a_1a_2 - b_1b_2, a_1b_2 + a_2b_1 \in 2 \mathbb{Z} \), it follows by the Subring Test that \( 2 \mathbb{G} \) is a subring of \( G \). \( \blacksquare \)

16.13 (a) **Proof** Since the zero matrix \( \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix} \) belongs to \( S \), it follows that \( S \neq \emptyset \). Let \( M_1, M_2 \in S \). Thus, \( M_1 = \begin{bmatrix} a_1 & b_1 \\ 0 & 0 \end{bmatrix} \) and \( M_2 = \begin{bmatrix} a_2 & b_2 \\ 0 & 0 \end{bmatrix} \), where \( a_i, b_i \in \mathbb{R} \) for \( 1 \leq i \leq 2 \). Then \( M_1 - M_2 = \begin{bmatrix} a_1 - a_2 & b_1 - b_2 \\ 0 & 0 \end{bmatrix} \) and \( M_1M_2 = \begin{bmatrix} a_1a_2 & a_1b_2 \\ a_1b_2 & b_1b_2 \end{bmatrix} \) belong to \( S \). By the Subring Test, \( S \) is a subring of \( M_2(\mathbb{R}) \). \( \blacksquare \)
Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19

(b) Proof Let $E = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix}$ and let $A = \begin{bmatrix} a & b \\ 0 & 0 \end{bmatrix}$ be an arbitrary element of $S$. Then

$$EA = \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} a & b \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} a & b \\ 0 & 0 \end{bmatrix}.$$ Let $C = \begin{bmatrix} 2 & 3 \\ 0 & 0 \end{bmatrix} \in S$. Then

$$CE = \begin{bmatrix} 2 & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} 1 & 1 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} 2 & 2 \\ 0 & 0 \end{bmatrix} \neq C.$$

16.15 Proof First we show that $(2\mathbb{Z}, +, \circ)$ is a ring. Certainly, $2\mathbb{Z}$ is closed under addition. Let $a, b, c \in 2\mathbb{Z}$ then $a = 2x, b = 2y$ and $c = 2z$, where $x, y, z \in \mathbb{Z}$. So, $a \circ b = (2x)(2y)/2 = 2xy$. Therefore, $(2\mathbb{Z}, +, \cdot)$ is closed under this multiplication. Because $(2\mathbb{Z}, +, \cdot)$ is a ring, where $\cdot$ is ordinary multiplication, $(2\mathbb{Z}, +, \circ)$ satisfies properties R1–R4 and the integer 0 is the zero element. Now $a \circ (b \circ c) = a \circ (bc)/2 = a(bc)/4 = (ab)c/4 = (ab/2) \circ c = (a \circ b) \circ c$, so $(2\mathbb{Z}, +, \circ)$ satisfies property R5. Finally, $a \circ (b + c) = a(b + c)/2 = (ab/2) + (ac/2) = (a \circ b) + (a \circ c)$ and so $(2\mathbb{Z}, +, \circ)$ satisfies property R6. Therefore, $(2\mathbb{Z}, +, \circ)$ is a ring. Since $a \circ b = ab/2 = ba/2 = b \circ a$, the ring $(2\mathbb{Z}, +, \circ)$ is commutative. Because $a \circ 2 = (a \cdot 2)/2 = a$ and $2 \in 2\mathbb{Z}$, the integer 2 is a unity for $(2\mathbb{Z}, +, \circ)$. Next, suppose that $a \circ b = 0$, where $a, b \in \mathbb{Z}$. Then $ab/2 = 0$ and so $ab = 0$, implying that $a = 0$ or $b = 0$. Therefore, $(2\mathbb{Z}, +, \circ)$ is an integral domain.

16.17 Solution The algebraic structure $(\mathbb{Z}, *, \circ)$ is not a ring. Since

$$1 \circ (0 * 0) = 1 \circ (-1) = 1 + (-1) + (-1) = -1$$

and

$$(1 \circ 0) * (1 \circ 0) = (1 + 0 + 0) * (1 + 0 + 0) = 1 * 1 = 1 + 1 = 1,$$

property R6 is not satisfied and so $(\mathbb{Z}, *, \circ)$ is not a ring.

16.19 The ring $R = M_2(\mathbb{R})$ and the subring $S = \left\{ \begin{bmatrix} a & 0 \\ 0 & a \end{bmatrix} : a \in \mathbb{R} \right\}$ of $M_2(\mathbb{R})$ have the desired properties.

16.21 Hint: First show that $\mathbb{Q}[i]$ is a subring of $\mathbb{C}$. Then show that every nonzero element of $\mathbb{Q}[i]$ is a unit.

16.23 (a) $\mathbb{Z}_n (n \geq 2)$
(b) $\mathbb{Z}$
(c) $M_2(\mathbb{Z})$
(d) $M_2(\mathbb{R})$

16.25 (3) occurs. Now explain your answer with justification.

EXERCISES FOR CHAPTER 17

17.1 Proof Let $u, v \in \mathbb{C}$ and $\alpha, \beta \in \mathbb{R}$. Then $u = a + bi$ and $v = c + di$, where $a, b, c, d \in \mathbb{R}$. Then $u + v = (a + bi) + (c + di) = (a + c) + (b + d)i$ and $\alpha u = \alpha(a + bi) = \alpha a + \alpha bi$. Since $a + c, b + d, \alpha a, \alpha b \in \mathbb{R}$, it follows that $u + v \in \mathbb{C}$ and $\alpha u \in \mathbb{C}$. Now $u + v = (a + c) + (b + d)i = (a + c) + (d + b)i = v + u$ and property 1 is satisfied. Let $w = e + fi$, where $e, f \in \mathbb{R}$. Then $(u + v) + w = [(a + c) + (b + d)i] + (e + fi) = [(a + c) + e] + [(b + d) + f]i = [a + (c + e)] + [b + (d + f)]i = (a + bi) + [(c + e) + (d + f)i] = u + (v + w)$; so property 2 is satisfied.

Let $z = 0 + 0i$. Since $u + z = (a + bi) + (0 + 0i) = a + bi = u$, property 3 is satisfied. Let $-u = (-a) + (-bi)$. Then $u + (-u) = (a + bi) + [(-a) + (-bi)] = 0 + 0i = z$ and property 4 is satisfied. Because $\alpha(u + v) = \alpha[(a + bi) + (c + di)] = \alpha[(a + c) + (b + d)i] = (\alpha a + \alpha c) + (\alpha b + \alpha d)i = (\alpha a + \alpha bi) + (\alpha c + \alpha di) = \alpha(a + bi) + \alpha(c + di) = \alpha u + \alpha v$, property 5 is satisfied. Now, $(\alpha + \beta)u = (\alpha + \beta)(a + bi) = (\alpha + \beta)u + (\alpha + \beta)bi = \alpha a + \beta a + \alpha bi + \beta bi = (\alpha a + \alpha bi) + (\beta a + \beta bi) = \alpha(a + bi) + \beta(a + bi) = \alpha u + \beta u$, thus, property 6 is satisfied. Since $(\alpha \beta)u = (\alpha \beta)(a + bi) = (\alpha \beta)a + (\alpha \beta)bi = \alpha(\beta a + \beta bi) = \alpha(\beta(a + bi)) = \alpha(\beta u)$, property 7 is satisfied. Finally, $1 \cdot u = 1 \cdot (a + bi) = 1 \cdot a + 1 \cdot bi = a + bi = u$, and so property 8 is satisfied.
17.3 (a) Since \((1, 0, 0) + (0, 1, 0) = (1, 0, 0)\) and \((0, 1, 0) + (1, 0, 0) = (0, 1, 0)\), property 1 is not satisfied and \(R^3\) is not a vector space.

(c) Let \(v = (1, 0, 0)\) and let \(z = (a, b, c)\) be the zero vector, where \(a, b, c \in \mathbb{R}\). Then \(v + z = (0, 0, 0) \neq v\); so property 3 is not satisfied and \(R^3\) is not a vector space.

(e) Let \(v = (1, 0, 0)\). Since \(1v = (0, 0, 1) \neq v\), property 8 is not satisfied and \(R^3\) is not a vector space.

17.5 Proof Observe that \(a(\mathbf{v}) = a((-1)\mathbf{v}) = (a(-1))\mathbf{v} = (-1)a\mathbf{v} = (-1)(-1)\mathbf{v} = (-1)(\mathbf{a}v) = -(\mathbf{av})\).

17.7 (a) The statement is false. Since \(z + z = z\), it follows that \(z = z\).

17.9 (a) The set \(W_i\) is a subspace of \(R^3\). Proof Since \((0, 0, 0) \in W_i\), it follows that \(W_i \neq \emptyset\). Let \(u, v \in W_i\) and \(a \in \mathbb{R}\). Then \(u = (a, a, a, a)\) and \(v = (b, b, b, b)\) for some \(a, b \in \mathbb{R}\). Then \(u + v = (a + b, a + b, a + b, a + b)\) and \(au = (aa, aa, aa, aa)\). Because \(u + v, av \in W_i\), it follows that \(W_i\) is a subspace of \(R^3\) by the Subspace Test.

(c) Since \((0, 0, 0, 1) \in W_i\) but \((0, 0, 0, 1) \notin W_5\), it follows that \(W_5\) is not closed under scalar multiplication and so \(W_5\) is not a subspace of \(R^4\).

17.11 (a) The set \(U_i\) is a subspace of \(R[x]\). Proof Since the zero function \(f_0\) defined by \(f_0(x) = 0\) for all \(x \in \mathbb{R}\) belongs to \(R[x]\), it follows that \(U_1 \neq \emptyset\). Let \(f, g \in U_1\) and \(a \in \mathbb{R}\). Then there exist constants \(a\) and \(b\) such that \(f(x) = a\) and \(g(x) = b\) for all \(x \in \mathbb{R}\). Then \((f + g)(x) = f(x) + g(x) = a + b\) and \((af)(x) = a(f(x)) = a\). Since \(f + g, af \in U_1\), it follows by the Subspace Test that \(U_1\) is a subspace of \(R[x]\).

(b) Since the function \(h\) defined by \(h(x) = x^2\) for all \(x \in \mathbb{R}\) belongs to \(U_2\), but \((0 \cdot h)(x) = 0 \cdot h(x) = 0 \cdot x^2 = 0\) does not belong to \(U_2\), it follows that \(U_2\) is not closed under scalar multiplication and \(U_2\) is not a subspace of \(R[x]\).

17.15 Proof Since \((0, 0), \text{that is, } x = 0 \text{ and } y = 0, \text{ is a solution of the equation, } (0, 0) \in S \text{ and so } S \neq \emptyset\). Let 
\[(x_1, y_1), (x_2, y_2) \in S \text{ and } a \in \mathbb{R}. \text{ Then } 3x_1 - 5y_1 - 0 \text{ and } 3x_2 - 5y_2 = 0. \text{ However, } 3(x_1 + x_2) - 5(y_1 + y_2) = (3x_1 - 5y_1) + (3x_2 - 5y_2) = 0. \text{ Thus, } (x_1 + x_2, y_1 + y_2) \in S. \text{ Furthermore, } 3(ax_1 - 5ay_1) = a(3x_1 - 5y_1) = a \cdot 0 = 0, \text{ and so } (ax_1, ay_1) \in S. \text{ Therefore, } S \text{ is a subspace of } R^2 \text{ by the Subspace Test.}

17.17 \(i = -\frac{1}{2}u_1 + \frac{1}{2}u_2 + \frac{1}{2}u_3\).

17.19 Proof Let \(v \in W\). Thus, \(v = c_1v_1 + c_2v_2 + \cdots + c_nv_n\), where \(c_i \in \mathbb{R}\) for \(1 \leq i \leq n\). Furthermore, let \(v_i = a_1w_1 + a_2w_2 + \cdots + a_mw_m\), where \(a_j \in \mathbb{R}\) for \(1 \leq i \leq n\) and \(1 \leq j \leq m\). Then
\[
v = [c_1, c_2, \ldots, c_n] \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_m \end{bmatrix} = [c_1, c_2, \ldots, c_n] A \begin{bmatrix} w_1 \\ w_2 \\ \vdots \\ w_m \end{bmatrix},
\]
where \(A = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix}\). Hence, \(v\) is a linear combination of \(w_1, w_2, \ldots, w_m\) and so \(v \in W\).

17.21 (a) Proof We first show that \((u, v) \subseteq (u, 2u + v)\). Observe that \(u \in (u, 2u + v)\) and \(v = (-2)u + 1 \cdot (2u + v) \in (u, 2u + v)\). By Exercise 17.19, \((u, v) \subseteq (u, 2u + v)\).

Next, we show that \((u, 2u + v) \subseteq (u, v)\). Since \(u \in (u, v)\) and \(2u + v\) is a linear combination of \(u \) and \(v\), it follows that \((u, 2u + v) \subseteq (u, v)\), again by Exercise 17.19.

17.23 (a) The set \(S\) is not linearly independent since \(1 \cdot (-1)\sin^2 x + (-1)\cos^2 x = 0\) for all \(x \in \mathbb{R}\).

(b) The set \(S\) is linearly independent. Proof Let \(a, b, c \in \mathbb{R}\) such that \(a \cdot 1 + b \cdot \sin x + c \cdot \cos x = 0\). We show that \(a = b = c = 0\). Letting \(x = 0, x = \pi/2\) and \(x = -\pi/2\), we obtain \(a + c = 0, a + b = 0\) and \(a - b = 0\), respectively. Solving these equations simultaneously, we obtain \(a = b = c = 0\).

17.27 Hint: Consider a proof by mathematical induction.
4 Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19

17.29 Proof Define the mapping \(T : \mathbb{R}^2 \rightarrow \mathbb{C}\) by \(T(a, b) = a + bi\). Assume that \(T(a, b) = T(c, d)\). Then \(a + bi = c + di\), which implies that \(a = c\) and \(b = d\). Thus, \((a, b) = (c, d)\). Hence, \(T\) is one-to-one. Next let \(a + bi \in \mathbb{C}\). Since \(T(a, b) = a + bi\), the mapping \(T\) is onto. Therefore, \(T\) is bijective. Let \(u = (a, b)\) and \(v = (c, d)\) be vectors in \(\mathbb{R}^2\) and let \(a \in \mathbb{R}\). Then \(T(u + v) = T(a + c, b + d) = (a + c) + (b + d)i = (a + bi) + (c + di) = T(u) + T(v)\). Also, \(T(au) = T(aa, ab) = (aa) + (ab)i = a(a + bi) = aT(u)\). Since \(T\) preserves both addition and scalar multiplication, \(T\) is a linear transformation.

17.33 (a) \(D(W) = \mathbb{R}\)
(b) \(D(W) = \{0\}\)
(c) \(\ker(T) = \mathbb{R}\).

17.35 (1) occurs.

EXERCISES FOR CHAPTER 18

18.1 Proof
(a) For the real number \(a - b\), exactly one of the following holds: \(a - b > 0\), \(a - b = 0\), \(a - b < 0\).

Therefore, exactly one of the following holds: \(a > b\), \(a = b\), \(a < b\).

(b) Let \(a > b\) and \(b > c\). Then \(a - b > 0\) and \(b - c > 0\). Thus \((a - b) + (b - c) = a - c > 0\) and so \(a > c\).

(c) Let \(a > b\). Then \(a - b > 0\). Since \(a - b = (a + c) - (b + c)\), it follows that \(a + c > b + c\).

(d) Let \(a > b\) and \(b > c\). Then \(a - b > 0\). So \((a - b)c = ac - bc > 0\). Hence, \(ac > bc\).

(e) Let \(a \neq 0\). Then \(a > 0\) or \(a < 0\). If \(a > 0\), then \(a^2 = a \cdot a > 0\). If \(a < 0\), then \(0 > a\) and so \(0 - a = -a > 0\). Thus, \((-a)(-a) = a^2 > 0\).

18.3 Claim: Properties (1) and (2) are satisfied if and only if \(c = 0\) or \(c \geq 1\).

Proof We already know that properties (1) and (2) are satisfied if \(c = 0\). Suppose then that \(c \geq 1\). If \(a > c\) and \(b > c\), then \(a + b > b + c > c + c > c\) and \(ab > bc > c \cdot c \geq c \cdot 1 = c\). Therefore, properties (1) and (2) are satisfied. We now verify the converse. Let \(c \in \mathbb{R}\) such that \(0 < c < 1\) and let \(a = b = \sqrt{c}\). Then \(c = 1 \cdot c > c \cdot c = c^2\) and so \(c > c^2\). Therefore, \(\sqrt{c} > c\) and so \(a > c\) and \(b > c\). However, \(ab = \sqrt{c} \sqrt{c} = c\) and so property (2) is not satisfied.

18.5 Proof Assume, to the contrary, that \(\mathbb{Z}_p\) is an ordered field. For the nonzero element \([1] \in \mathbb{Z}_p\), either \([1] > [0]\) or \([1] < [0]\). If \([1] < [0]\), then \([0] > [1]\) and so \([0] - [1] = [-1] > [0]\). Thus, \([-1] - [1] = [1] > [0]\), which is a contradiction. Thus, \([1] > [0]\). However, if \(p\) terms \([1]\) are added, then we obtain \([1] + [1] + \cdots + [1] = [p] > [0]\). Since \([p] = [0]\), this is also a contradiction.

18.7 Proof Since \(F\) is an ordered field and \(F \subseteq \mathbb{R}\), it follows that \(0, 1 \in F\). Let \(n \in \mathbb{N}\). Since \(F\) is a field, the sum of \(n\) terms \(1 \in n \in F\). Also, \(-1 \in F\). Consequently, \(\mathbb{Z} \subseteq F\). Let \(b \in \mathbb{Z}\) where \(b \neq 0\). By property 8, \(1/b \in F\). Let \(a/b \in Q\), where \(a, b \in \mathbb{Z}\). Then \(a, 1/b \in F\) and so \(a(1/b) = a/b \in F\).

18.9 (a) Proof Let \(a \in S\). Then \(\inf(S) \leq a \leq \sup(S)\) and so \(\inf(S) \leq \sup(S)\).

(b) Claim: The set \(S\) has the property that \(\inf(S) = \sup(S)\) if and only if \(S\) consists of a single real number.

Proof First, if \(S\) consists of a single real number \(s\), then \(\max(S) = \min(S) = s\) and so \(\inf(S) = \sup(S) = s\). We now verify the converse using a proof by contrapositive. Suppose that \(\inf(S)\) and \(\sup(S)\) exist and \(S\) does not consist of a single real number. Let \(r_1, r_2 \in S\), where \(r_1 < r_2\) say. Then \(\inf(S) \leq r_1 < r_2 \leq \sup(S)\) and so \(\inf(S) < \sup(S)\). Hence, \(\inf(S) \neq \sup(S)\).

18.11 Proof
(a) Let \(x \in T\). Since \(T \subseteq S\), it follows that \(x \in S\). Thus, \(\inf(S) \leq x \leq \sup(S)\). Therefore, \(\sup(S)\) is an upper bound for \(T\) and \(\inf(S)\) is a lower bound for \(T\). By the Completeness Axiom, \(\inf(T)\) and \(\sup(T)\) exist.

(b) Since \(x \leq \sup(S)\) for each \(x \in S\), it follows that \(x \leq \sup(S)\) for each \(x \in T\). Therefore, \(\sup(S)\) is an upper bound for \(T\) and so \(\sup(T) \leq \sup(S)\). Similarly, \(\inf(S) \leq \inf(T)\).

18.13 Proof First, suppose that \(\inf(S) = a\). Then \(a\) is a lower bound for \(S\). Furthermore, each real number \(y\) with \(y > a\) is not a lower bound for \(S\). Hence, there exists \(x \in S\) such that \(x < y\) and so \(a \leq x < y\).
For the converse, assume that $a$ is a lower bound for $S$ and for every real number $y > a$, there exists $x \in S$ such that $a \leq x < y$. Since $a$ is a lower bound for $S$, it follows that $\inf(S)$ exists and $a \leq \inf(S)$. Assume, to the contrary, that $a < \inf(S)$. Therefore, there exists $x \in S$ such that $a \leq x < \inf(S)$. This, however, contradicts the fact that $\inf(S)$ is a lower bound for $S$.

**18.15 Proof** Since $r$ is a positive rational number, $r = a/b$, where $a, b \in \mathbb{N}$. Since $a \geq 1$ and $b \geq 1$, it follows that $4a^2 \geq 4a \geq a/b$ and so $\sqrt{4a^2} > \sqrt{a/b}$. Let $n = 2a$. Then $n > \sqrt{r}$.

**18.17 Proof** Suppose that $S$ is a finite set. Then $S = \{r_1, r_2, \ldots, r_n\}$, where $a < r_1 < r_2 < \cdots < r_n < b$ and $r_i \in \mathbb{Q}$ for each $i (1 \leq i \leq n)$. By Theorem 18.10, there exists a rational number $r$ such that $r_1 < r < r_2$. Thus, $r \in S$, which is a contradiction.

**18.19 Claim:** The set $S$ is dense in $\mathbb{R}$.

**Proof** Let $a, b \in \mathbb{R}$ such that $a < b$. Then $a/\sqrt{2} < b/\sqrt{2}$. By Theorem 18.10, there exists a rational number $r$ such that $a/\sqrt{2} < r < b/\sqrt{2}$. Therefore, $a < r < b$.

**18.21 Proof**

(a) Let $A_1, A_2, \ldots, A_n$ be bounded sets. Then for each $i (1 \leq i \leq n)$, let $a_i$ be a lower bound and $b_i$ an upper bound for $A_i$. Thus, $a_i \leq x \leq b_i$ for each $x \in A_i$. Let $a = \min(a_1, a_2, \ldots, a_n)$ and $b = \max(b_1, b_2, \ldots, b_n)$. Then $a \leq x \leq b$ for each $x \in \bigcup_{i=1}^{n} A_i$.

(b) Let $B = \max(\sup(A_1), \sup(A_2), \ldots, \sup(A_n))$, say $\sup(A_1) = B$. Then $\sup(A_i) \leq \sup(A_1) = B$ for $1 \leq i \leq n$. Let $x \in \bigcup_{i=1}^{n} A_i$. Then $x \in A_i$ for some $i (1 \leq i \leq n)$. Thus, $x \leq \sup(A_i) \leq B$. Therefore, $\sup(A_1 \cup \ldots \cup A_n) = \max(\sup(A_1), \sup(A_2), \ldots, \sup(A_n))$.

Assume, to the contrary, that $b = \sup(A_1 \cup \ldots \cup A_n) < \max(\sup(A_1), \sup(A_2), \ldots, \sup(A_n)) = B$.

Since $b < B = \sup(A_1)$, it follows that $b$ is not an upper bound for $A_1$; so there exists $x \in A_1$ such that $b < x \leq B$. However, $x \in \bigcup_{i=1}^{n} A_i$, contradicting the fact that $b = \sup(\bigcup_{i=1}^{n} A_i)$.

Similarly, $\inf(A_1 \cup \ldots \cup A_n) = \min(\inf(A_1), \inf(A_2), \ldots, \inf(A_n))$.

**18.23 (a) Proof** Let $a, b \in \mathbb{R}$ with $a < b$. Since $S$ is dense in $\mathbb{R}$, there exists $c \in S$ such that $c \in (a, b)$. Let $r = \min(b - c, c - a)$. Since $S$ is an open set, there exists an $\epsilon$-neighborhood $N(c)$ of $c$ for which $\epsilon < r$ such that $N(c) \subseteq S$. Since $T$ is dense in $\mathbb{R}$, there exists $d \in T$ such that $d \in (c - \epsilon, c + \epsilon)$. Therefore, $d \in S \cap T$ and $d \in (a, b)$ and so $S \cap T$ is dense in $\mathbb{R}$.

(b) Yes. The proof in (a) does not require $T$ to be an open set.

(c) No. Let $S = \mathbb{Q}$ be the set of rational numbers and $T = \mathbb{R} - \mathbb{Q}$ the set of irrational numbers. Then neither $S$ nor $T$ is open but both are dense in $\mathbb{R}$. The set $S \cap T = \emptyset$ is not dense in $\mathbb{R}$.

**18.25 Proof** First, we show that $\text{Int}(S) \cap \text{Int}(T) \subset \text{Int}(S \cap T)$. Let $x \in \text{Int}(S) \cap \text{Int}(T)$. Then $x \in \text{Int}(S)$ and $x \in \text{Int}(T)$. Since $x$ is an interior point of $S$, there is a neighborhood $N_1$ of $x$ such that $N_1 \subseteq S$. Similarly, there is a neighborhood $N_2$ of $x$ such that $N_2 \subseteq T$. Then $N = N_1 \cap N_2$ is an open set and a neighborhood of $x$ such that $N \subseteq S \cap T$. Hence, $x \in \text{Int}(S \cap T)$.

Next, we show that $\text{Int}(S \cap T) \subset \text{Int}(S) \cap \text{Int}(T)$. Let $x \in \text{Int}(S \cap T)$. Since $x$ is an interior point of $S \cap T$, there is a neighborhood $N$ of $x$ such that $N \subseteq S \cap T$. Thus, $N \subseteq S$ and $N \subseteq T$. So $x$ is an interior point of $S$ and an interior point of $T$. Therefore, $x \in \text{Int}(S) \cap \text{Int}(T)$.

**18.27 Proof**

(a) Assume, to the contrary, that there exist two nonempty open sets $A$ and $B$ of real numbers with $A \cap B = \emptyset$ such that $A \cup B = \mathbb{R}$. Let $a \in A$ and $b \in B$. We may assume that $a < b$. Let $I = [a, b]$ and let $S = \{x \in I : x \in B\}$. Hence, $b \in S$ and $a$ is a lower bound of $S$. Thus, $\text{inf}(S)$ exists, say $\text{inf}(S) = c$. Since $a$ is an interior point of $A$, there is an open set $N_1$ such that $N_1 \subseteq S$ and $a \in N_1$. Therefore, $\epsilon > 0$ such that $N_1(a) \subseteq A$. Thus, $c \notin N_1(a)$ and so $a < c < b$. Since $c \in \mathbb{R} = A \cup B$, either $c \in A$ or $c \in B$. Suppose that $c \in A$. Since $A$ is an open set, there exists an $\epsilon > 0$ such that $N_1(c) \subseteq A$. However then, each $x \in N_1(c)$ with $x > c$ is a lower bound of $S$, which is a contradiction. Thus, $c \in B$. Since $B$ is an open set, there exists an $\epsilon' > 0$ such that $N_1(c) \subseteq B$. Then each $x \in (c - \epsilon', c)$ is a point of $S$, contradicting the fact that $c$ is a lower bound of $S$. 
(b) Assume, to the contrary, that there is a nonempty proper subset $A$ of $\mathbb{R}$ that is both open and closed. Then $B = \overline{A}$ is also a nonempty proper subset of $\mathbb{R}$ that is both open and closed. However then, $A$ and $B$ would be a counterexample to (a), which is impossible. 

18.29 Solution

(a) $S$ is closed, $\text{Bd}(S) = \{x \in \mathbb{N} : x \leq 2002\}$ and $\text{Int}(S) = (1, 2) \cup (3, 4) \cup (5, 6) \cup \cdots \cup (2001, 2002)$.

(b) $S$ is open, $\text{Bd}(S) = (-2, 8]$ and $\text{Int}(S) = (-2, 8)$.

(c) $S$ is open, $\text{Bd}(S) = [-3, 0, 3)$ and $\text{Int}(S) = (-3, 0) \cup (0, 3)$.

(d) $S = \{1\}$ is closed, $\text{Bd}(S) = \{1\}$ and $\text{Int}(S) = \emptyset$.

(e) $S = [0, 1]$ is neither open nor closed, $\text{Bd}(S) = [0, 1]$ and $\text{Int}(S) = (0, 1)$. 

18.31 Solution

(a) Let $S = (Q \cap [1, 2]) \cup (2, \infty)$. Then $S = (-\infty, 1) \cup ((\mathbb{R} - Q) \cap [1, 2])$. Thus, $\text{Acc}(S) = [1, \infty)$ and $\text{Acc}(\overline{S}) = (-\infty, 2]$; so $\text{Acc}(S) \cap \text{Acc}(\overline{S}) = [1, 2]$.

(b) Let $S = \{x \in \mathbb{R} : x \geq 0\}$. Then $\overline{S} = \{x \in \mathbb{R} : x < 0\}$. Thus, $\text{Bd}(S) = \text{Bd}(\overline{S}) = \emptyset$.

(c) Let $S = \{x \in \mathbb{R} : x \leq 1\}$. Then $\overline{S} = \{x \in \mathbb{R} : x < 1\}$. Then $\text{Cl}(S) = [1, \infty)$ and $\text{Cl}(\overline{S}) = (-\infty, 1]$; so $\text{Cl}(S) \cap \text{Cl}(\overline{S}) = \emptyset$.

18.33 Solution

For $k \in \mathbb{N}$, let $A_k = \left\{ k + \frac{1}{n} : n \in \mathbb{N}\right\}$ and let $S = \bigcup_{k \in \mathbb{N}} A_k$. Then $\text{Acc}(S) = \mathbb{N}$ and $\text{Acc}(S) \cap S = \emptyset$.

18.35 (a) Proof Let $x \in \text{Cl}(S \cap T)$. Then $x \in S \cap T$ or $x \in \text{Acc}(S \cap T)$. If $x \in S \cap T$, then $x \in S$ and $x \in T$; so $x \in \text{Cl}(S)$ and $x \in \text{Cl}(T)$. Thus, $x \in \text{Cl}(S) \cap \text{Cl}(T)$. Next, suppose that $x \in \text{Acc}(S \cap T)$. Then every deleted neighborhood of $x$ contains a point in $S \cap T$. Consequently, every deleted neighborhood of $x$ contains a point in $S$ and a point in $T$ and so $x \in \text{Acc}(S)$ and $x \in \text{Acc}(T)$. Therefore, $x \in \text{Acc}(S) \cap \text{Acc}(T)$, which implies that $x \in \text{Cl}(S) \cap \text{Cl}(T)$ in this case as well.

(b) Solution Let $A = Q \cap [0, 1]$ and $B = [0, 1] - Q$. Then $\text{Cl}(A \cap B) = \emptyset$ and $\text{Cl}(A) \cap \text{Cl}(B) = [0, 1]$.

18.37 Solution

(a) $S = [1, 2]$. Here, $\text{Bd}(S) = [1, 2]$ and $\text{Acc}(S) = S = [1, 2]$.

(b) $S = \{0\} \cup \left\{ \frac{1}{n} : n \in \mathbb{N}\right\}$. Here, $\text{Acc}(S) = \{0\}$ and $\text{Bd}(S) = S$.

(c) $S = \mathbb{Q}$. Here, $\text{Bd}(S) = \text{Acc}(S) = \mathbb{R}$.

18.39 Proof

(a) Let $b \in \text{Bd}(S)$. We claim that $b \in S$. If this were not the case, then since $N^\epsilon_S(b) \cap S \neq \emptyset$ for each $\epsilon > 0$, it follows that $b \in \text{Acc}(S)$, which is impossible. Thus, $b \in S$ and so $\text{Bd}(S) \subseteq S$. Hence, $S$ is a closed set by Theorem 18.15. This establishes (1).

Since $\text{Int}(S) \subseteq S$ and $\text{Bd}(S) \subseteq S$, it follows that $\text{Int}(S) \cup \text{Bd}(S) \subseteq S$. Next, we show that $S \subseteq \text{Int}(S) \cup \text{Bd}(S)$. Suppose that $x \in S$ and $x \notin \text{Bd}(S)$, that is, $x \in S - \text{Bd}(S)$. Since $x$ is not a boundary point of $S$, there is a neighborhood $N(x)$ of $x$ such that $N(x) \cap \overline{S} = \emptyset$. Thus, $N(x) \subseteq S$ and so $x \in \text{Int}(S)$. Therefore, $S \subseteq \text{Int}(S) \cup \text{Bd}(S)$ and so $S = \text{Int}(S) \cup \text{Bd}(S)$. This establishes (2).

Since $\text{Int}(S) \subseteq \text{Acc}(S)$, it remains to show that $\text{Acc}(S) \subseteq \text{Int}(S)$. Let $y \in \text{Acc}(S)$. Since $S$ is closed, it follows by Theorem 18.20 that $\text{Acc}(S) \subseteq S$ and so $y \in S$. Since $\text{Acc}(S) \cap \text{Bd}(S) = \emptyset$ and $S = \text{Int}(S) \cup \text{Bd}(S)$, it follows that $y \in \text{Int}(S)$. Therefore, $\text{Acc}(S) \subseteq \text{Int}(S)$ and so $\text{Int}(S) = \text{Acc}(S)$. This establishes (3).

(b) Assume, to the contrary, that there exists a set $S$ of real numbers such that $\text{Bd}(S) \neq \emptyset$, $\text{Acc}(S) \neq \emptyset$ and $\text{Bd}(S) \cap \text{Acc}(S) = \emptyset$. By (a), $\text{Int}(S) = \text{Acc}(S)$. Since $\text{Int}(S)$ is an open set by Exercise 18.22 and $\text{Acc}(S)$ is a closed set by Exercise 18.38, it follows that $\text{Acc}(S)$ is both open and closed. By Exercise 18.27, $\text{Acc}(S) = \mathbb{R}$. By Theorem 18.20, $S = \mathbb{R}$ and so $\text{Bd}(S) = \emptyset$, which produces a contradiction.
18.41 Solution
(a) \( \text{Bd}(S) = \{0, 1, 2, 3\}, \text{Cl}(S) = [0, 1] \cup [2, 3], \text{Int}(S) = (0, 1) \cup (2, 3) \) and \( \text{Cl}(S) - \text{Int}(S) = \{0, 1, 2, 3\} \).
(b) \( \text{Bd}(S) = \text{Cl}(S) = S \cup \{0\}, \text{Int}(S) = \emptyset \) and \( \text{Cl}(S) - \text{Int}(S) = S \cup \{0\} \).
(c) \( \text{Bd}(S) = \mathbb{N} \cup \{0\}, \text{Cl}(S) = (-\infty, 0] \cup \mathbb{N}, \text{Int}(S) = (-\infty, 0) \) and \( \text{Cl}(S) - \text{Int}(S) = \mathbb{N} \cup \{0\} \).

18.43 Solution
(a) Let \( S = \{ \frac{1}{n} : n \in \mathbb{N} \} \). Then \( \text{Acc}(S) = \{0\} \) and \( \text{Acc}(\text{Acc}(S)) = \emptyset \).
(b) Let \( S = \{ x \in \mathbb{Q} : 0 \leq x \leq 1 \} \). Then \( \text{Bd}(S) = [0, 1] \) and \( \text{Bd}(\text{Bd}(S)) = [0, 1] \).
(c) No such example exists. For every set \( S \) of real numbers, it follows by Theorem 18.23 that \( \text{Cl}(S) \) is a closed set. Thus, \( \text{Cl}(\text{Cl}(S)) = \text{Cl}(S) \).
(d) No such example exists. For every set \( S \) of real numbers, it follows by Exercise 18.22(a) that \( \text{Int}(S) \) is an open set. Thus, \( \text{Int}(\text{Int}(S)) = \text{Int}(S) \).

18.45 Proof Since \( \text{Int}(S) \cup \text{Bd}(S) \cup \text{Int}(\overline{S}) \subseteq \mathbb{R} \), it remains only to show that \( \mathbb{R} \subseteq \text{Int}(S) \cup \text{Bd}(S) \cup \text{Int}(\overline{S}) \) or that every real number belongs to at least one of \( \text{Int}(S), \text{Bd}(S) \) and \( \text{Int}(\overline{S}) \), then we have the desired result. Thus, we may assume that \( x \notin \text{Int}(S) \) and \( x \notin \text{Int}(\overline{S}) \). Let \( N(x) \) be any neighborhood of \( x \). Since \( x \notin \text{Int}(S) \), it follows that \( N(x) \nsubseteq S \) and so \( N(x) \) contains a point of \( \overline{S} \). Similarly, since \( x \notin \text{Int}(\overline{S}) \), it follows that \( N(x) \nsubseteq \overline{S} \) and so \( N(x) \) contains a point of \( S \). Therefore, every neighborhood of \( x \) contains a point of \( S \) and a point of \( \overline{S} \). Thus, \( x \) is a boundary point of \( S \) and so \( x \in \text{Bd}(S) \). Therefore, \( \mathbb{R} \subseteq \text{Int}(S) \cup \text{Bd}(S) \cup \text{Int}(\overline{S}) \).

18.47 Proof First, we show that \( \text{Int}(S) \subseteq \bigcup_{L \in T} L \). Let \( x \in \text{Int}(S) \). Since \( x \) is an interior point of \( S \), there exists a neighborhood \( N(x) \) such that \( N(x) \subseteq S \). Because \( N(x) \) is an open set with \( N(x) \subseteq S \), it follows that \( N(x) \subseteq T \) and so \( x \in \bigcup_{L \in T} L \). Therefore, \( \text{Int}(S) \subseteq \bigcup_{L \in T} L \).

Next, we show that \( \bigcup_{L \in T} L \subseteq \text{Int}(S) \). Let \( y \in \bigcup_{L \in T} L \). Thus, \( y \in L \) for some \( L \in T \). Because \( L \) is an open set, there exists a neighborhood \( N(y) \) of \( y \) such that \( N(y) \subseteq L \). However, \( L \subseteq S \) and so \( N(y) \subseteq S \). Hence, \( y \) is an interior point of \( S \) and so \( y \in \text{Int}(S) \). Therefore, \( \bigcup_{L \in T} L \subseteq \text{Int}(S) \).

18.49 Claim: The set \( S \) consists of a single element.

Proof Assume, to the contrary, that \( S \) is a nonempty compact set of real numbers such that every open cover of \( S \) contains a subcover consisting of a single set belonging to the open cover but \( S \) contains two or more elements. Let \( a, b \in S \), where \( a < b \). Say, \( \mathcal{E} = (b - a) \). Now, let \( S_1 = (-\infty, a), S_2 = N(a), S_3 = N(b) \) and \( S_4 = (b, \infty) \). Since \( C = \{S_1, S_2, S_3, S_4\} \) is an open cover of \( \mathbb{R} \), it follows that \( C \) is an open cover of \( S \). Since \( S_2 \) is the only open set in \( C \) containing \( a \) and \( S_1 \) is the only open set in \( C \) containing \( b \), there is no single set in \( C \) that covers \( S \), a contradiction.

18.51 Solution
(a) The set \( S \) is compact since it's closed and bounded.
(b) The set \( S = [2, 6] \) is compact since it's closed and bounded.
(c) The set \( S \) is compact since it's closed and bounded.
(d) The set \( S = (0, 1] \) is not compact since it's not closed. It does not contain the accumulation point 0.
(e) The set \( S = [1, 11] \) is compact since it's closed and bounded.

18.53 Solution For each positive integer \( n \), let \( S_n = \left( \frac{1}{n+1}, \frac{2}{n} \right] - \left( \frac{1}{n+1}, \frac{1}{n} \right) \). Thus, \( S_1 = \left( \frac{1}{2}, \frac{3}{2} \right), S_2 = \left( \frac{1}{3}, \frac{2}{3} \right) \) and \( S_3 = \left( \frac{1}{4}, \frac{5}{4} \right) \). Hence, \( S_n \) contains the element \( \frac{1}{n} \) of \( S \) but no other element of \( S \). Therefore, \( S \subseteq \bigcup_{n \in \mathbb{N}} S_n \), and so \( C = \{S_n\}_{n \in \mathbb{N}} \) is an open cover of \( S \). Since \( S \) is infinite and each element of \( S \) belongs to only one open set \( S_n \), the only subcover of \( S \) is \( C \) itself.

18.55 Proof
(a) Since \( \text{Acc}(S) = [0, 2] \) is not a subset of \( S \), it follows that \( S \) is not closed. By Theorem 18.27, \( S \) is not compact.
8 Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19

(b) Let $y$ be an irrational number such that $0 < y < 2$. For example, we could choose $y = \sqrt{2}$. For each $n \in \mathbb{N}$, let $S_n = (-1, y - \frac{1}{n}) \cup (y + \frac{1}{n}, 3)$. Then $S \subseteq \cup_{n \in \mathbb{N}} S_n$. Hence, $C = \{S_n\}_{n \in \mathbb{N}}$ is an open cover of $S$. Suppose that $C$ contains a finite open subcover of $S$. Then there exists a finite set $J$ of positive integers such that $\{S_n\}_{n \in J}$ is an open cover of $S$. Let $m$ be a largest element of $J$. Then $\cup_{n \in J} S_n = (-1, y - \frac{1}{m}) \cup (y + \frac{1}{m}, 3)$. Since the rational numbers are dense in $\mathbb{R}$ (Theorem 18.10), it follows that there is a rational number $r$ with $y - \frac{1}{m} < r < y$. Hence, $r \in S$ but $r \notin \cup_{n \in J} S_n$, a contradiction. ■

18.57 Proof

(a) Let $S$ be a compact set of real numbers. Then $S$ is bounded. Furthermore, since $K \subseteq S$, it follows that $K$ is bounded. Since $K$ is closed and bounded, $K$ is compact.

(b) Since $K$ is a compact set by (a), it follows by Corollary 18.28 that $K$ has both a maximum and a minimum element. ■

18.59 Proof First, assume that $\text{Cl}(S)$ is compact. Then $\text{Cl}(S)$ is bounded. Since $S \subseteq \text{Cl}(S)$, it follows that $S$ is bounded.

Next, assume that $S$ is bounded. Then there exist real numbers $a$ and $b$ with $a < b$ such that $S \subseteq [a, b]$. Now $\text{Acc}(S) \subseteq \text{Acc}([a, b]) = [a, b]$ and so $\text{Cl}(S)$ is a bounded set. Then $S \subseteq \text{Cl}(S)$ is closed by Theorem 18.23, it follows that $\text{Cl}(S)$ is compact. ■

18.61 Proof Let $\{S_n\}_{n \in \mathbb{N}}$ be an infinite collection of nonempty compact sets of real numbers and let $S = \bigcap_{n \in \mathbb{N}} S_n$. If $S = \emptyset$, then $S$ is compact. So, we may assume that $S \neq \emptyset$. By Corollary 18.18, $S$ is closed. Let $S_0 \in \{S_n\}_{n \in \mathbb{N}}$. Since $S_0$ is compact, $S_0$ is bounded and so $S_0$ has a lower bound $a$ and an upper bound $b$. Then $x \in S_0$. Then $x \in S_0$ and so $a \leq x \leq b$. Therefore, $S$ is bounded and so $S$ is compact. ■

18.63 (a) Proof Since $A \cap B$ is compact, $A \cap B$ is closed. Since $A$ and $B$ are open sets, $A \cap B$ is open by Theorem 18.16. Thus, $A \cap B$ is both open and closed. By Exercise 18.27(b), it follows that $A \cap B = R$ or $A \cap B = \emptyset$. Since $A \cap B$ is compact, $A \cap B$ is bounded and so $A \cap B = \emptyset$. ■

(b) The statement is true. Proof Let $S_n = \left( \frac{1}{n}, -\frac{1}{n} \right)$ for $n \in \mathbb{N}$. Then each set $S_n$ is open. Let $S = \cap_{n \in \mathbb{N}} S_n$. Then $S = \{0\}$, which is a nonempty compact set. ■

18.65 Proof Let $x \in S$ and let $\epsilon_x = |r - x|/2$. Then $N_{\epsilon_x}(x)$ and $N_{\epsilon_x}(r)$ are disjoint open sets containing $x$ and $r$, respectively. Then $C = \{N_{\epsilon_x}(x)\}_{x \in S}$ is an open cover of $S$. Since $S$ is compact, $C$ has a finite subcover $C' = \{N_{\epsilon_1}(x_1), N_{\epsilon_2}(x_2), \ldots, N_{\epsilon_n}(x_n)\}$. Let $\epsilon = \min_{1 \leq i \leq n} \{\epsilon_x\}$. Then $U = \bigcup_{i=1}^{n} N_{\epsilon_i}(x_i)$ and $V = N_r(r)$ are disjoint open sets such that $S \subseteq U$ and $r \notin V$. ■

18.67 Proof Assume first that $S$ is a compact set of real numbers. Since $S$ is bounded, it follows by the Bolzano–Weierstrass Theorem that every infinite subset of $S$ has an accumulation point. Since $S$ is closed, every accumulation point of $S$ belongs to $S$.

We now verify the converse. Let $S$ be a set of real numbers having the property that every infinite subset of $S$ has an accumulation point belonging to $S$. We show that $S$ is compact, that is, that $S$ is bounded and closed.

First, we show that $S$ is bounded. Assume, to the contrary, that $S$ is unbounded. Then $S$ contains an unbounded set of positive real numbers or an unbounded set of negative real numbers, say the former. Therefore, for each $n \in \mathbb{N}$, there exists $x_n \in S$ such that $x_n > n$. Let $X = \{x_1, x_2, \ldots\}$. Since $X$ is infinite, $X$ has an accumulation point $a \in S$. Certainly $a > 0$, for otherwise, $\epsilon_1 = 1 - a > 0$ and the deleted neighborhood $N^*_a(a)$ of $a$ contains no point of $X$, which is impossible. Hence, $a > 0$. By the Archimedean Principle, there is a positive integer $n$ such that $a > n$ and by the Principle of Well-Ordering, there is a smallest positive integer $m$ such that $m > a$. Thus, $m - 1 \leq a < m$. Let $\epsilon_2 = \min\{|x_i - a|: a \neq x_i, 1 \leq i \leq m - 1\}$.

Then the deleted neighborhood $N^*_{\epsilon_2}(a)$ of $a$ contains no points of $X$ and so $a \notin \text{Acc}(X)$, a contradiction. Hence, $S$ is bounded.

Next, we show that $S$ is closed. Assume, to the contrary, that $a$ is an accumulation point of $S$ but $a \notin S$. Then for each $n \in \mathbb{N}$, there exists $y_n \in S$ such that $|y_n - a| < 1/n$. Let $Y = \{y_n : n \in \mathbb{N}\}$, which is an infinite subset
of $S$. By assumption, $Y$ has an accumulation point $b$ belonging to $S$. So, for each $\epsilon > 0$, there exists a positive integer $K$ such that if $k$ is an integer with $k > K$, then both $1/k < \epsilon/2$ and $|y_k - b| < \epsilon/2$. Hence,

$$|a - b| \leq |a - y_k| + |y_k - b| < \epsilon/2 + \epsilon/2 = \epsilon,$$

which implies that $a = b$ and so $a \in S$, which is a contradiction. Therefore, $S$ is closed. 

18.69 **Solution**

(a) $8 - 6i$

(b) $-11 - 2i$

(c) $-12 + 5i$

(d) $2$

(e) $31 + 33i$

(f) $-1$.

18.71 **Solution**

$(\sqrt{2} + i)^3 = 2\sqrt{2} + 3 \cdot 2i - 3\sqrt{2} - i = -\sqrt{2} + 5i$.

18.73 **Proof**

(a) Let $z = a + bi$, where $a, b \in \mathbb{R}$. Then $\bar{z} = a - bi = a + bi = z$.

(b) Let $z_1 = a + bi$ and $z_2 = c + di$, where $a, b, c, d \in \mathbb{R}$. Then

\[
\frac{z_1 + z_2}{z_1 - z_2} = \frac{(a + bi) + (c + di)}{(a + bi) - (c + di)} = \frac{(a + c) + (b + d)i}{(a + c) - (b + d)i}.
\]

Also,

\[
\overline{\frac{z_1 + z_2}{z_1 - z_2}} = \frac{a + bi + c + di}{a + bi - c - di} = \frac{(a + c) + (b + d)i}{(a + c) - (b + d)i} = \overline{\frac{z_1 + z_2}{z_1 - z_2}}.
\]

18.75 **Proof**

(a) We proceed by induction. The statement is trivially true for $n = 1$. Assume, for every $k$ complex numbers $\beta_1, \beta_2, \ldots, \beta_k$, where $k \in \mathbb{N}$, that

$$\overline{\beta_1 \cdot \beta_2 \cdots \beta_k} = \overline{\beta_1} \cdot \overline{\beta_2} \cdots \overline{\beta_k}.$$

Let $\alpha_1, \alpha_2, \ldots, \alpha_{k+1}$ be $k + 1$ complex numbers. By the induction hypothesis and Exercise 18.73(c),

\[
\overline{\alpha_1 \cdot \alpha_2 \cdots \alpha_{k+1}} = \overline{(\alpha_1 \cdot \alpha_2 \cdots \alpha_k \cdot \alpha_{k+1})} = \overline{\alpha_1} \cdot \overline{\alpha_2} \cdots \overline{\alpha_k} \cdot \overline{\alpha_{k+1}}
\]

By the Principle of Mathematical Induction, the statement is true for every positive integer $n$.

(b) Letting $\alpha_i = \alpha$ for $i = 1, 2, \ldots, n$ in (a), we have $\overline{\alpha^n} = \alpha^n$.

18.77 **Solution**

By the quadratic formula,

\[
z = \frac{-2a \pm \sqrt{4a^2 - 20a^2}}{2} = \frac{-2a \pm \sqrt{-16a^2}}{2} = \frac{-2a \pm 4ai}{2} = -a \pm 2ai.
\]

18.79 **Solution**

Since $z^2 - 6z + 9 = (z - 3)^2 = 6i$, it follows that $z - 3 = \pm \sqrt{6i}$ and so $z = 3 \pm (\sqrt{3} + \sqrt{3}i)$. The two roots of the equation are therefore $(3 + \sqrt{3}) + \sqrt{3}i$ and $(3 - \sqrt{3}) - \sqrt{3}i$.

**Alternate Solution**

By the quadratic formula,

\[
z = \frac{6 \pm \sqrt{36 - 4(9 - 6i)}}{2} = \frac{6 \pm \sqrt{24i}}{2} = 3 \pm \sqrt{6i}.
\]

Since $(\sqrt{3} + \sqrt{3}i)^2 = 6i$, the two roots of the equation are $3 + (\sqrt{3} + \sqrt{3}i) = (3 + \sqrt{3}) + \sqrt{3}i$ and $3 - (\sqrt{3} + \sqrt{3}i) = (3 - \sqrt{3}) - \sqrt{3}i$.
10  Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19

18.81  Solution  
(a) By the quadratic formula, \( z = \frac{(2 \pm \sqrt{4 - 8})}{2} = (2 \pm 2i)/2 = 1 \pm i \).
(b) Since \( z^4 - 16 = (z^2 - 4)(z^2 + 4) = (z - 2)(z + 2)(z^2 + 4) = 0 \), this equation has the four roots 2, -2, 2i, -2i.
(c) Since \( z^3 - 3z^2 + z - 3 = z^2(z - 3) + (z - 3) = (z - 3)(z^2 + 1) = 0 \), this equation has the three roots 3, i, -i.
(d) Since \( z^4 + 3z^2 + 2 = (z^2 + 1)(z^2 + 2) = 0 \), this equation has the four roots \( i, -i, \sqrt{2}i, -\sqrt{2}i \). ♦

18.83  Proof  Assume that \( p(\alpha) = 0 \) for some \( \alpha \in \mathbb{C} \). Since \( p(z) = a_0 + a_1z + a_2z^2 + \cdots + a_nz^n \), where \( a_i \in \mathbb{R} \) for \( 0 \leq i \leq n \), it follows that

\[
a_0 + a_1\alpha + a_2\alpha^2 + \cdots + a_n\alpha^n = 0.
\]

Since \( a_i \in \mathbb{R} \) for \( 0 \leq i \leq n \), it follows by Exercises 18.74 and 18.75 that

\[
p(\overline{\alpha}) = a_0 + a_1\overline{\alpha} + a_2\overline{\alpha}^2 + \cdots + a_n\overline{\alpha}^n
\]

\[
= a_0 + a_1\overline{\alpha} + a_2\overline{\alpha}^2 + \cdots + a_n\overline{\alpha}^n
\]

\[
= a_0 + a_1\overline{\alpha} + a_2\overline{\alpha}^2 + \cdots + a_n\overline{\alpha}^n
\]

\[
= a_0 + a_1\overline{\alpha} + a_2\overline{\alpha}^2 + \cdots + a_n\overline{\alpha}^n = p(\alpha) = 0.
\]

18.85  Proof  
(a) Observe that \( |z_1|^2 = |a + bi|^2 = (\sqrt{a^2 + b^2})^2 = a^2 + b^2 \) and\n
\[
z_1 \cdot \overline{z_1} = (a + bi)(a - bi) = a^2 - b^2i^2 = a^2 + b^2.
\]

(b) Observe that \( |Re(z_1)| = |a| = \sqrt{a^2} \leq \sqrt{a^2 + b^2} = |z_1| \) and \( |Im(z_1)| = |b| = \sqrt{b^2} \leq \sqrt{a^2 + b^2} = |z_1| \).

(c) Observe that \( |z_1| = \sqrt{a^2 + b^2} = \sqrt{(-a)^2 + (-b)^2} = | - z_1| \) and

\[
|z_1| = \sqrt{a^2 + b^2} = \sqrt{a^2 + (-b)^2} = |\overline{z_1}|.
\]

(d) Observe that

\[
|z_1z_2| = |(a + bi)(c + di)| = |(ac - bd) + (ad + bc)i|
\]

\[
= \sqrt{(ac - bd)^2 + (ad + bc)^2} = \sqrt{(a^2 + b^2)(c^2 + d^2)}
\]

\[
= |z_1||z_2|.
\]

Also,

\[
\left| \frac{z_1}{z_2} \right| = \left| \frac{a + bi}{c + di} \right| = \left| \frac{(a + bi)(c - di)}{(c + di)(c - di)} \right|
\]

\[
= \left| \frac{(ac + bd) + (bc - ad)i}{c^2 + d^2} \right| = \frac{\sqrt{(a^2 + b^2)(c^2 + d^2)}}{c^2 + d^2}
\]

\[
= \frac{\sqrt{a^2 + b^2}}{\sqrt{c^2 + d^2}} = \frac{|z_1|}{|z_2|}.
\]

18.87  Solution  
(a) By Exercise 18.86(a),

\[
|z| = |(1 - \sqrt{3}i)(4 + 3i)(12 - 5i)|
\]

\[
= |1 - \sqrt{3}i||4 + 3i||12 - 5i| = 2 \cdot 5 \cdot 13 = 130.
\]

(b) By Exercise 18.86(b), \( |z| = |(3 - i)^4| = |3 - i|^6 = \sqrt{10}^6 = 1000 \). ♦
18.89 **Proof**  Let \( z_1, z_2 \in C \). By Exercise 18.88, when \( n = 2 \),
\[
|z_1| = |(z_1 - z_2) + z_2| \leq |z_1 - z_2| + |z_2|.
\]
Therefore, \( |z_1 - z_2| \geq |z_1| - |z_2| \).  

18.91 **Solution**

(a) For the complex number \( \sqrt{3} + i, x = \sqrt{3}, y = 1 \) and \( r = \sqrt{x^2 + y^2} = 2 \). Also, \( \cos \theta = x/r = \sqrt{3}/2 \), \( \sin \theta = y/r = 1/2 \) and \( \tan \theta = y/x = 1/\sqrt{3} \). Since \( \theta \) is an angle in the first quadrant, \( \theta = \frac{\pi}{6} \). Therefore, 
\[
\sqrt{3} + i = r \cos \theta + i \sin \theta = 2 \left( \cos \frac{\pi}{6} + i \sin \frac{\pi}{6} \right).
\]

(b) For \( -\sqrt{3} - i, x = -\sqrt{3}, y = -1 \) and \( r = 2 \). Also, \( \cos \theta = -\sqrt{3}/2, \sin \theta = -1/2 \) and \( \tan \theta = -\sqrt{3} \). Since \( \theta \) is in the 3rd quadrant, \( \theta = \frac{-\pi}{6} \). Therefore, 
\[
-\sqrt{3} - i = 2 \left( \cos \frac{-\pi}{6} + i \sin \frac{-\pi}{6} \right).
\]

(c) For \( 1 - \sqrt{3}i, x = 1, y = -\sqrt{3} \) and \( r = 2 \). Also, \( \cos \theta = 1/2, \sin \theta = -\sqrt{3}/2 \) and \( \tan \theta = -\sqrt{3} \). Since \( \theta \) is in the 4th quadrant, \( \theta = -\frac{\pi}{6} \). Therefore, 
\[
1 - \sqrt{3}i = 2 \left( \cos \frac{-\pi}{6} + i \sin \frac{-\pi}{6} \right).
\]

(d) \( 5 = 5(\cos 0 + i \sin 0) \).

(e) For \( 4 - 4i, x = 4, y = -4 \) and \( r = 4\sqrt{2} \). Also, \( \cos \theta = 1/\sqrt{2}, \sin \theta = -1/\sqrt{2} \) and \( \tan \theta = -1 \). Since \( \theta \) is in the 4th quadrant, \( \theta = -\frac{\pi}{4} \). Therefore, 
\[
4 - 4i = 4 \left( \cos \frac{-\pi}{4} + i \sin \frac{-\pi}{4} \right).
\]

(f) For \( 2\sqrt{3} - 2i, x = 2\sqrt{3}, y = -2 \) and \( r = 4 \). Thus, \( \cos \theta = \sqrt{3}/2, \sin \theta = -1/2 \) and \( \tan \theta = -1/\sqrt{3} \). Since \( \theta \) is in the 4th quadrant, \( \theta = -\frac{\pi}{6} \). So 
\[
2\sqrt{3} - 2i = 4 \left( \cos \frac{-\pi}{6} + i \sin \frac{-\pi}{6} \right).
\]

18.93 **Solution**

(a) \( \sqrt{2} \left( \cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right) = \sqrt{2} \left( \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}} i \right) = 1 + i \)

(b) \( 2 \left( \cos \frac{-\pi}{4} + i \sin \frac{-\pi}{4} \right) = 2 \left( \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}} i \right) = 1 - i \)

(c) \( 2 \left( \cos \frac{\pi}{3} + i \sin \frac{\pi}{3} \right) = 2 \left( -\frac{\sqrt{3}}{2} + \frac{1}{2} i \right) = -\sqrt{3} + i \)

(d) \( 4 \left( \cos \pi + i \sin \pi \right) = 4(-1) = -4 \).

18.95 **Solution**  Here \( x = -1, y = -\sqrt{3} \) and \( r = \sqrt{x^2 + y^2} = 2 \). Thus, \( \cos \theta = -1/2, \sin \theta = -\sqrt{3}/2 \) and \( \tan \theta = \sqrt{3} \). Since \( \theta \) is an angle in the 3rd quadrant, \( \theta = \frac{2\pi}{3} \). Therefore, 
\[
-1 - \sqrt{3}i = 2 \left( \cos \frac{2\pi}{3} + i \sin \frac{2\pi}{3} \right).
\]
Hence,
\[
(-1 - \sqrt{3}i)^{12} = \left[ 2 \left( \cos \frac{4\pi}{3} + i \sin \frac{4\pi}{3} \right) \right]^{12} = 2^{12} \left( \cos 16\pi + i \sin 16\pi \right) = 4096.
\]

18.97 **Solution**  The roots of \( z^6 - 1 = 0 \) are \( \cos 0 + i \sin 0 = 1, \cos \frac{\pi}{3} + i \sin \frac{\pi}{3} = \frac{1}{2} + \frac{\sqrt{3}}{2}i, \)
\[
\cos \frac{2\pi}{3} + i \sin \frac{2\pi}{3} = -\frac{1}{2} + \frac{\sqrt{3}}{2}i, \cos \pi + i \sin \pi = -1, \cos \frac{4\pi}{3} + i \sin \frac{4\pi}{3} = -\frac{1}{2} - \frac{\sqrt{3}}{2}i \text{ and}
\]
\[
\cos \frac{5\pi}{3} + i \sin \frac{5\pi}{3} = \frac{1}{2} - \frac{\sqrt{3}}{2}i.
\]

18.99 **Solution**  Since \( \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}i = \cos \frac{\pi}{4} + i \sin \frac{\pi}{4}, \) it follows that
\[
\alpha = \left( \cos \frac{\pi}{4} + i \sin \frac{\pi}{4} \right)^8 = \cos 2\pi + i \sin 2\pi = 1.
\]
We therefore seek the eight roots of \( z^8 - \alpha = z^8 - 1 = 0 \) or equivalently of \( z^8 = 1 \). Since \( 1 = \cos 0 + i \sin 0, \) the roots are
\[
z_k = \cos \left( \frac{0 + 2k\pi}{8} \right) + i \sin \left( \frac{0 + 2k\pi}{8} \right) \text{ for } k \in \{0, 1, 2 \ldots, 7\}.
\]
Hence \( z_0 = 1, z_1 = \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}i, z_2 = i, z_3 = -\frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}i, z_4 = -1, z_5 = -\frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}i, z_6 = -i \) and \( z_7 = \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}i \).
12 Answers and Hints to Selected Odd-Numbered Exercises in Chapters 16–19

18.101 Solution

(a) For the complex number \(3 + 4i\), it follows that \(x = 3\), \(y = 4\) and \(r = \sqrt{x^2 + y^2} = 5\). Thus,
\[
\cos \theta = \frac{x}{r} = \frac{3}{5}, \quad \sin \theta = \frac{y}{r} = \frac{4}{5} \text{ and } \tan \theta = \frac{y}{x} = \frac{4}{3}.
\]
So \(\theta = \arctan\left(\frac{4}{3}\right)\). Therefore,
\[
3 + 4i = 5e^{\arctan(4/3)}.
\]
(b) For the complex number \(2 - 2i\), it follows that \(x = 2\), \(y = -2\) and \(r = 2\sqrt{2}\). So \(\theta = -\frac{\pi}{4}\). Therefore,
\[
2 - 2i = 2\sqrt{2}e^{-\frac{i\pi}{4}}.
\]
(c) For the complex number \(-\sqrt{3} + i\), it follows that \(x = -\sqrt{3}\), \(y = 1\) and \(r = 2\). Hence,
\[
\tan \theta = \frac{y}{x} = -1/\sqrt{3} \text{ and so } \theta = \frac{5\pi}{6}.
\]
Therefore, \(-\sqrt{3} + i = 2e^{\frac{5i\pi}{6}}\).

18.103 Solution We seek the two roots of the equation
\[
z^2 = 3e^{\frac{\pi}{3}i} = 3 \left(\cos \frac{\pi}{3} + i \sin \frac{\pi}{3}\right)
\]
\[
= 3 \left(\frac{1}{2} + \frac{\sqrt{3}}{2}i\right) = \frac{3}{2} + \frac{3\sqrt{3}}{2}i.
\]
The two roots are
\[
z_k = \sqrt{3} \left(\cos \frac{\pi}{6} + i \sin \frac{\pi}{6}\right) \text{ for } k = 0, 1.
\]
Hence,
\[
z_0 = \sqrt{3} \left(\cos \frac{\pi}{6} + i \sin \frac{\pi}{6}\right) = \sqrt{3} \left(\frac{\sqrt{3}}{2} + \frac{1}{2}i\right) = \frac{3}{2} + \frac{\sqrt{3}}{2}i
\]
\[
z_1 = \sqrt{3} \left(\cos \frac{7\pi}{6} + i \sin \frac{7\pi}{6}\right) = \sqrt{3} \left(-\frac{\sqrt{3}}{2} - \frac{1}{2}i\right) = -\frac{3}{2} - \frac{\sqrt{3}}{2}i.
\]

EXERCISES FOR CHAPTER 19

19.1 (a) Property (1) is not satisfied. For example, \(d(2, 1) = -1 < 0\).

Property (2) is satisfied since \(d(x, y) = y - x = 0\) if and only if \(x = y\).

Property (3) is not satisfied. For example, \(d(2, 1) = -1\) and \(d(1, 2) = 1\).

Property (4) is satisfied since \(d(x, y) + d(y, z) = (y - x) + (z - y) = z - x = d(x, z)\).

(b) Since \(d(x, y) = (x - y) + (y - x) = 0\), property (1) is satisfied.

Since \(d(1, 2) = 0\) and \(1 \neq 2\), property (2) is not satisfied.

Since \(d(x, y) = d(y, x) = 0\), property (3) is satisfied.

Since \(d(x, y) + d(y, z) = d(x, z) = 0\), property (4) is satisfied.

19.3 Hint: For \(P_1 = (x_1, y_1)\) and \(P_2 = (x_2, y_2)\), \(d(P_1, P_2) = d(x_1, x_2) + d(y_1, y_2) \geq 0 + 0 = 0\), so (1) is satisfied. If \(P_1 = P_2\), then \(x_1 = x_2\) and \(y_1 = y_2\). Thus, \(d(P_1, P_2) = d(x_1, x_2) + d(y_1, y_2) = 0 + 0 = 0\). Conversely, if \(d(P_1, P_2) = 0\), then \(d(x_1, x_2) + d(y_1, y_2) = 0\). Since \(d(x_1, x_2) \geq 0\) and \(d(y_1, y_2) \geq 0\), it follows that \(d(x_1, x_2) = 0\) and \(d(y_1, y_2) = 0\). So, \(x_1 = x_2\) and \(y_1 = y_2\) and it follows that \(P_1 = P_2\); so (2) is satisfied. Now properties (3) and (4) remain to be considered.

19.5 Hint: It is straightforward to show that properties (1)–(3) are satisfied. So, only property (4) needs to be investigated. Consider \(d(x, y)\) for various pairs \(x, y\) of elements of \(A\).

19.7 (a) Let \(P_1 = (1, 2)\) and \(P_2 = (1, 3)\). Since \(d(P_1, P_2) = 0\) and \(P_1 \neq P_2\), it follows that \((\mathbb{R}^2, d)\) is not a metric space.

19.9 (a) Hint: Consider beginning a proof as follows: Let \(O\) be an open set in \((\mathbb{R}^2, d)\). To show that \(O\) is open in \((\mathbb{R}^2, d')\), we show that every point \(P_0 = (x_0, y_0)\) is the center of an open sphere in \((\mathbb{R}^2, d')\) that is contained in \(O\).
Exercises for Chapter 19

19.11 (a) Hint: Consider beginning a proof as follows: Let \( P_0 = (x_0, y_0) \in \mathbb{R}^2 \), and let \( \epsilon > 0 \) be given. We show that there exists \( \delta > 0 \) such that if \( d(P, P_0) < \delta \), where \( P = (x, y) \), then \( d'(f(P), f(P_0)) < \epsilon \). Notice that \( d(P, P_0) = |x - x_0| + |y - y_0| \) and \( d'(f(P), f(P_0)) = \left| \frac{1}{2}(x - y) - \frac{1}{2}(x_0 - y_0) \right| \).

19.13 (a) No, since \( X \notin S_1 \).
(b) No, since \( \{a, b\} \cap \{a, c\} = \{a\} \notin S_2 \).
(c) Yes.

19.17 Hint: Consider beginning a proof as follows: Observe that the result is true if \( |X| \leq 1 \). So we may assume that \( |X| \geq 2 \). Assume that \((X, \tau)\) is a metric space, say \((X, d)\). First we show that \( \{a\} \) is open for every \( a \in X \). Let \( r = \min\{d(x, a) : x \in X - \{a\}\} \). Since \( X - \{a\} \) is finite, \( r > 0 \). Then \( S_r(a) = \{a\} \) is open. Now complete the proof of this implication.

For the converse, assume that \((X, \tau)\) is a discrete topological space. Then \( \tau = \mathcal{P}(X) \). Define the “discrete” metric \( d \) on \( X \) by \( d(x, y) = 1 \) if \( x \neq y \) and \( d(x, y) = 0 \) if \( x = y \).

19.19 Hint: It is useful to prove the following Lemma: If \( O_1, O_2, \ldots, O_n \) are countable sets, where \( n \in \mathbb{N} \), then \( \bigcup_{i=1}^{n} O_i \) is countable.

19.21 Let \( a \) and \( b \) be distinct real numbers, where, say \( a < b \), and let \( O_a \) and \( O_b \) be open sets containing \( a \) and \( b \), respectively. Since \((a, \infty) \subset O_a \) and \((b, \infty) \subset O_b \), it follows that \((b, \infty) \subset O_a \cap O_b \). So, \( O_a \cap O_b \neq \emptyset \).

19.22 We claim that \( f(1) = 1 \).

\textbf{Proof} \quad Let \( f(a) = 1 \). Since \( \{1\} \) is an open set and \( f \) is continuous, it follows that \( f^{-1}(\{1\}) = \{a\} \) is open. Since \( 1 \in \{a\} \), it follows that \( a = 1 \). Thus, \( f(1) = 1 \). \hfill \Box

19.27 (3) occurs. The fact that \( O_1, O_2, \ldots, O_n (n \in \mathbb{N}) \) are infinite sets does not imply that \( \bigcap_{a \in \mathbb{N} O_a} \) is infinite. For example, let \( X = \mathbb{Z}, n = 2, O_1 = \{k \in \mathbb{Z} : k \geq 0\} \) and \( O_2 = \{k \in \mathbb{Z} : k \leq 0\} \). Then \( O_1 \) and \( O_2 \) are infinite, but \( O_1 \cap O_2 = \{0\} \).

19.29 (a) \textbf{Solution} \quad The statement is true.

\textbf{Proof} \quad Let \( b \in X - \{a\} \), and let \( d(b, a) = r \). Then the open sphere \( S_r(b) \) is contained in \( X - \{a\} \). \hfill \Box

19.31 The statement is false. Now a counterexample must be found.

terms of, 373
Set(s), 14–34
cardinalities of, 16, 278–300
Cartesian product of, 33–34, 122–123
complement of, 24, 117
countable, 281
countably infinite, 281
denumerable, 280–287
describing of, 14–17
difference of, 24, 117
disjoint, 24
element of, 14
empty, 15
equal, 20
finite, 16, 279
index, 28
indexed collection of, 27–30
infinite, 16, 279
intersection of, 23, 117
member of, 14
null, 15
numerically equivalent, 279–280
operations on, 23–26, 117–121
pairwise disjoint, 31
partition of, 31–32, 236
power, 21
relative complement, 25, 117
uncountable, 281, 288–292
union of, 23, 117
universal, 20
void, 15
well-ordered, 153
Smaller cardinality, 294
Smallest element, 152
Stabilizer, 421
Statement(s), 38–40
biconditional, 53–55
characterization of, 76–77
component, 57
compound, 57
conditional, 45
conjunction of, 44
disjunction of, 43
equivalent, 54
implication of, 45–52
logically equivalent, 60–64
negation of, 41–42
quantified, 65–73, 205–209
testing, 211–218
truth value of, 38
Strategy
proof, 86
for a solution, 211–214
String, 328
bit string, \( n \)-, 329
length of, 328
Strong Form of Induction, 170
Strong Pigeonhole Principle, 338–339
Strong Principle of Mathematical Induction, 170–174, 189
Subcases, 94
Subgroup, 418–422
Subgroup Test, 418–419
Subsequence, 340
Subset(s), 18–21
proper, 21
Such that, 207
Sufficient, 47
necessary and, 54
Sum (of a series), 373
Surjective function, 257
Syntactic function, 257
Symbols
consistent, 8
frozen, 8
meaning of, 8
proper use of, 6–8
sentence structure with, 6–7
words separated from, 7
Symmetric
group, 411
relation, 226
Table
group, 407
operation, 407
truth, 40
Tautology, 57
Terms
of a sequence, 365
of a series, 373
Testing statements, 211–218
Theorem, 81
existence, 141
Three Prisoners Problem, 136–137
Transitive relation, 227
Tree diagram, 328
root, 328
Triangle
equilaterial, 50
isosceles, 50
Pascal, 348–349
Triangle inequality, 115–116
Trivial proof, 82–83
True (truth value), 38
Truth
table, 40
value, 38
Twain, Mark, 4
Twin primes, 41, 321
Uncountable set, 281, 288–292
Unimodal sequence, 357
Union
of indexed collection of sets, 29
of two sets, 23, 117
Unique element, 143
Uniqueness, 143
Universal
quantifier, 65
set, 20
Vacuous proof, 83–84
Vacuously, 84
Variables, dummy, 29
Venn diagram, 20–21
Void set, 15
Well-defined
addition in \( \mathbb{Z}_n \), 246
function, 262
multiplication in \( \mathbb{Z}_n \), 246
Well-ordered set, 153
Well-Ordering Principle, 153
Wiles, Andrew, 202
Without loss of generality, 96
WLOG, 96
WOLOG, 96
Word, \( n \)-letter, 347
Writing
common words and phrases, 10–12
displays, 8–9
mathematical, 5–12
mathematical expressions, 8–9
symbols, 6–8
Zermelo, Ernst, 299
